COLLISION.

COLLISION, from the Latin *Colliſio*, a breaking, knocking, or daſhing together, in *Philoſophy* and in *Mechanics*, means the meeting, mutual ſtriking, or congreſs, of two or more bodies, one of which at leaſt is in motion. The colliſions of bodies, and the reſults ariſing from thoſe colliſions, form by far the greateſt part of the operations of nature, as well as of artificial mechanics; hence the induſtry of man has ſpared no pains in the inveſtigation of the laws which regulate thoſe motions, and in the performance of experiments tending to confirm and to illuſtrate the ſame. In the theory of colliſion or percuſſion, the ſimpleſt caſes are conſidered firſt, and ſuch, indeed, as cannot actually take place in nature; for inſtance, two bodies are ſuppoſed to move equally (that is, each of them, or one at leaſt, to run through equal lengths in equal portions of time) in non-reſiſting mediums, and thoſe bodies are farther ſuppoſed to be either hard, or ſoft, or elaſtic. A hard body is that whoſe parts retain their reſpective ſituation or figure in all caſes, not yielding to any ſtroke or percuſſion. A ſoft body is that whoſe parts yield to any ſtroke, and have no power to recover their original ſituation; and laſtly, an elaſtic body is that whoſe parts yield to any ſtroke, but preſently regain their original form and ſituation.. Now, in nature, (as far as we know) there are no bodies perfectly elaſtic or perfectly unelaſtic; including under the latter name both thoſe that are perfectly hard and thoſe that are perfectly ſoft. All the bodies we are acquainted with are partially elaſtic, but in various degrees; nor can their motions take place without meeting with ſome obſtruction. Yet the laws of colliſion, under the above-mentioned ſuppoſitions, being demonſtratively deduced from the general laws of motion, which are juſtly aſſumed as axioms, determine the phenomena which would take place if thoſe ſuppoſitions were real; it being afterwards more eaſy and practicable to eſtimate, and to allow for thoſe deviations of practical reſults from the abſtract theory, which ariſe from the imperfect elaſticity of bodies, from reſiſtances of mediums, from friction, &c.

The theory of colliſion is derived from ſir Iſaac Newton's third law of motion, which ſays, that action and re-action are always equal and contrary to each other. See LAWS *of motion.*

Definition 1. *The reſpective velocities or celerities of bodies are proportional to the ſpaces which they deſcribe in a given time.* Thus, if a body, A, paſſes through an extenſion of 10 feet in one ſecond of time, whilſt the body, B, runs through an extenſion of 100 feet in the ſame time, then the reſpective celerities of thoſe bodies are ſaid to be as 10 to 100; or as one to ten.

Def. 2. *The bodies are ſaid to ſtrike directly againſt each other, when in ſtriking, there occurs no reaſon why they ſhould turn towards one ſide rather than towards another; ſo that both before and after the ſtroke, the motion is in the ſame ſtraight line, unleſs it be all deſtroyed.*

Def. 3. *In every other caſe the ſtroke is ſaid to be oblique.* The principal propoſition belonging to this theory, conſiders two bodies that ſtrike directly againſt each other, and the reſult is conciſely expreſſed by ſir Iſaac Newton in the following words: "the quantity of motion, that is gathered by taking the ſum of the motions made towards the ſame part, and the difference of thoſe made towards the contrary parts, is not altered by the action of bodies amongſt themſelves." For the ſake of perſpicuity we ſhall endeavour to demonſtrate this propoſition, by conſidering the two caſes ſeparately.

THEOREM I.

If a body, A, (*Plate* XV. *Mechanics*, fig. 1.) *ſtrike directly againſt another body*, B, *which is either at reſt, or moving in the ſame direction, but ſlower; the ſum of the motions in both the bodies towards the ſame parts, will remain the ſame after the ſtroke, as it was before that ſtroke.*

Let C D expreſs the motion of the body A, and E F the motion of the body B; *viz.* that whilſt A moves from C to D, B moves from E to F. Therefore, the ſum of the motions is C D plus E F. Now, ſince it moves with greater velocity than B moves with, it neceſſarily follows, that A muſt overtake, and ſtrike againſt B. And it will appear, that after the ſtroke the ſum of the motions is the ſame as it was before, *viz.* C D plus E F. For ſince action and re-action are equal (3d law of motion), if A, by ſtriking on B, communicates to it the additional motion F G; it muſt loſe as much itſelf; *viz.* D K (equal to F G) muſt be ſubtracted from C D. So that after the ſtroke, C K is the motion of A, and E G that of B; and the ſum of thoſe motions is C K plus E G, equal to C D plus E F; for, ſince F G is equal to D K, add E F and C K to both, and it will be $FG + EF + CK$ equal to $KD + CK + EF$; *viz.* $EG + CK = CD + EF$.

The various caſes of this propoſition are as follow: If F G is equal to C D, then K and C coincide, and C K vaniſhes or becomes equal to nothing (as in *fig.* 2.); hence, after the ſtroke, A will be at reſt.

If F G exceed C D; then K will fall beyond C; and the motion of A will become retrograde or negative (as in *fig.* 3.) Therefore, the ſum of the motions towards the ſame part is the difference between E G and C K; *viz.* E G minus C K.

If B ſtood at reſt, then its motion becomes equal to 0, and in that caſe the ſum of the motions is reduced to C D.

THEOREM II.

If two bodies, moving towards contrary parts, ſtrike directly againſt each other, the ſum of their motions towards the ſame parts (which is the difference of their motions towards contrary parts) before and after the ſtroke, will always remain the ſame towards the ſame parts.

Let the body, A (*fig.* 4.), move from C towards D, and let C D repreſent its motion, whilſt the body, B, moves in a contrary direction from E towards F, and let E F repreſent its motion.

Make D H equal to E F; then C H is the difference of the motions towards the contrary parts, and is, at the ſame time, the ſum of the motions towards the ſame part; *viz.* towards G. Now, after the ſtroke, the ſame, C H, will be as the ſum of the motions towards the ſame part, *viz.* towards G.

Let the motion of B, after the ſtroke, be towards G, and let it be repreſented by E G. Therefore, the force communicated to B is F E plus E G, that is, F G. But (by the 3d law of motion) making D K equal to F G, D K will repreſent the motion loſt by A; ſo that if D K be ſubtracted from C D, the remainder, C K, will be the motion of A towards G. Now, ſince D K is equal to F G, and D H is equal to F E; it will be D K minus D H, (*viz.* K H), equal to F G minus F E (*viz.* E G). Therefore, ſince K H is equal to E G; K H will repreſent the motion of B after the ſtroke, and C K will repreſent the motion of A; ſo that C K plus K H is equal to C H, and is the ſum of the motions of both the bodies towards G.

If F G is equal to C D (as in *fig.* 5.); then K and C coincide, conſequently the motion of A becomes equal to *o*.

If F G exceeds C D (as in *fig.* 6.) K will fall beyond C, and the motion of A will be retrograde; but (ſince F G is equal to D K, and F E to D H) K H will be equal to E G; therefore, taking C K from both, C H will be equal to E G minus C K. But C H was as the ſum of the motions towards G before the ſtroke, and E G minus C K is as the ſum of the motions towards the ſame part; namely, as the difference of the motions towards the contrary parts after the ſtroke. Therefore, the ſum of the motions towards the ſame part will be the ſame both before and after the ſtroke.

Having demonſtrated the two ſimpleſt theorems belonging to the doctrine of colliſion, wherein the equality of the motions before and after the ſtroke has been conſidered, it is now neceſſary to examine the direction, the velocity, and the momentum of the bodies after the ſtroke; and for this purpoſe the properties of the centre of gravity muſt be recollected.

But, that property of the centre of gravity, which is more immediately concerned with the preſent ſubject, is briefly expreſſed in the following lines:

If bodies, moving in the ſame ſtraight line, ſtrike againſt each other, the ſtate of their common centre of gravity will not thereby be altered; viz. *it will either remain at reſt, or it will continue to move in the ſame ſtraight line, exactly as it moved before the ſtroke.* See CENTER *of Gravity*.

THEOREM III.

Let there be two non-elaſtic bodies (*viz.* either perfectly hard or perfectly ſoft); *and if one of them move in a ſtraight line, whilſt the other is at reſt in that line, or is moving in the ſame direction, but at a ſlower rate, or is moving in the contrary direction; then thoſe bodies muſt ſtrike directly againſt each other, and after the ſtroke they will either remain at reſt, or they will move on together, conjointly with their common centre of gravity.—Their momentum, after the ſtroke, will be equal to the ſum of their momentums before the ſtroke, if they both moved in the ſame direction; but it will be equal to the difference of their momentums if they moved in contrary directions.—Their velocity, after the ſtroke, will be equal to the quotient that ariſes from dividing the ſum of their momentums, if they both moved the ſame way, or the difference of their momentums, if they moved contrary ways, by the ſum of their quantities of matter.*

That, after the ſtroke, the two bodies muſt either remain at reſt or move on together, is evident; for, ſince they are not elaſtic, there exiſts no power that can effect their ſeparation. With reſpect to the momentum, it muſt be obſerved, that where the bodies meet (by the 3d law of motion), whatever part of the momentum is loſt by one of the bodies, muſt be acquired by the other; therefore, if before the ſtroke the bodies moved the ſame way, their joint momentum, after the ſtroke, will be equal to the ſum of their momentums before the ſtroke. If one of the bodies was at reſt, then, as its momentum is equal 0, the joint momentum will be equal to the momentum of the other body before the meeting. If the bodies moved towards each other, then their momentum, after the meeting, will be equal to the difference of their former momentums; and if in this caſe their momentums are equal, then their difference vaniſhes; that is, the bodies will remain at reſt after their meeting.

The laſt part of the theorem is evident; for the momentum of a body in motion is equal to the product of the velocity multiplied by the quantity of matter. See MOMENTUM.

The weights and velocities of the two bodies before their meeting being given, the velocity, after the meeting, may be determined by the following method, which is applicable to the four caſes of *figs.* 7, 8, 9, and 10. Let A and B be the two bodies, C their common centre of gravity, and D the place of their meeting. Make D E equal to D C, ſo that the point, D, may be between C and E; then D E will repreſent the velocity after their meeting; for, ſince the bodies, after their meeting, move together conjointly with their common centre of gravity; and the centre of gravity has the property mentioned immediately before the third theorem; it follows that the velocity of their common centre of gravity after their meeting, muſt be equal to its velocity before the meeting; *viz.* D E muſt be equal to C D, and is the ſame as the velocity of the two bodies after the meeting, becauſe, then, they move together with the centre of gravity.

Fig. 7. ſhews when the bodies move the ſame way. *Fig.* 8. ſhews the body, B, at reſt before the ſtroke, in which caſe B and D coincide. In *fig.* 9. the two bodies move towards each other; and *fig.* 10. ſhews the two bodies moving towards each other with equal momentums, in which caſe they will remain at reſt after the meeting. In all thoſe four figures, the reſpective velocities of the bodies are repreſented by A D and B D, and A B is their difference. The reſpective momentums are repreſented by the product of the weight of A multiplied by A D, and of the weight of B multiplied by B D. The momentum after the meeting is repreſented by the weights of both the bodies multiplied by D E.

Example of the computation of the firſt caſe, fig. 7.—Let A weigh 10 lb. and move at the rate of 4 feet per minute. Let B weigh 6 lb., and move at the rate of 2 feet per minute, and let the diſtance A B be 32 feet. The centre of gravity is found by ſaying $16 : 32 :: 10 : BC = \frac{32 \times 10}{16} = 20$ feet; hence $AC = 12$ feet. Put $BD = x$, and A D will be equal to $32 + x$. Then the time employed by A in moving from A to D, is equal to the quotient of the ſpace, $32 + x$, divided by its velocity; *viz.* $= \frac{32 + x}{4}$. And the time employed by B in moving from B to D, is equal to the quotient of the ſpace, x, divided by the velocity of B, *viz.* $= \frac{x}{2}$. But, ſince the bodies meet at D, thoſe times muſt be equal; that is, $\frac{32 + x}{4} = \frac{x}{2}$; and by the reſolution of this ſimple equation, we have $64 + 2x = 4x$; and $x = 32 = BD$.

Then $DE = DB + BC = 32 + 20 = 52$ feet; *viz.* after the meeting, the two bodies will move from D to E, which are 52 feet apart, in as much time as each of them employed in going to D; *viz.* 16 minutes. Therefore, in order to find how many feet per minute the bodies will run over after the meeting, divide 52 by 16, and the quotient, $3\frac{1}{4}$, is the anſwer.

The magnitude or quantity of the ſtroke is deduced from the third general law of motion, and from the nature of the momentum of a body in motion, which is equal to the product of the quantity of matter, or weight of the body, multiplied by the velocity, conſequently in the ſame body the momentum is proportionate to the velocity. The particulars relative to the magnitude of the ſtroke, are expreſſed in the following theorem.

Theorem IV.

If a body in motion ſtrike directly againſt another body, the magnitude of the ſtroke is proportional to the momentum loſt, at the concourſe, by the more powerful body. Alſo, when the latter body is at reſt, the quantity of the ſtroke is proportional to the velocity of the former body.—If the ſecond body be moving in the ſame direction with the firſt, but at a ſlower rate, the magnitude of the ſtroke will be the ſame as if the ſecond body ſtood ſtill, and the firſt impinged upon it with a velocity equal to the difference of their velocities.—And, laſtly, if the bodies move directly towards each other, the magnitude of the ſtroke is the ſame as if one of the bodies ſtood at reſt, and the other ſtruck it with the ſum of their velocities.

Thus much may ſuffice with reſpect to the congreſs or colliſion of non-elaſtic bodies. It is now neceſſary to ſtate the particulars belonging to the congreſs of elaſtic bodies; *viz.* of thoſe whoſe parts yield to any impreſſion, but frequently recover their ſituation, by re-acting the contrary way with a force, which, in bodies perfectly elaſtic, is equal to the impreſſion or ſtroke received. There are innumerable degrees of elaſticity. See Elasticity.

Theorem V.

When two bodies, that are perfect elaſtic, ſtrike directly againſt each other, their relative velocity (by which is meant the exceſs whereby the velocity of the ſwifter body exceeds that of the ſlower) *will be the ſame before and after the ſtroke;* viz. *they will recede from each other with the ſame velocity with which they approached before the ſtroke.*

The magnitude of the ſtroke (Theor. IV.) is proportional to the reſpective velocities. And in bodies that are perfectly elaſtic, the reſtoring force is equal to the compreſſing one; therefore, if the momentums of the bodies produced a certain compreſſion, the elaſtic force muſt re-act on the bodies with equal power; hence the bodies will be forced to recede from each other with the ſame velocity with which they approached each other.

From what has been ſtated above, the reſults ariſing from the congreſs of bodies that are perfectly elaſtic, may be eaſily deduced in all the variety of caſes in which the two bodies may be conceived to meet. The particulars upon which thoſe reſults more immediately depend, are, firſt, that the diſtances of two bodies from their common centre of gravity are inverſely as their weights; (ſee Center *of Gravity* and its properties); ſecondly, that the ſtate or the uniform motion of the centre of gravity of bodies is not altered by the mutual action of thoſe bodies on each other; thirdly, that in bodies that are perfectly elaſtic, the reſtoring is equal to the compreſſing force; and fourthly, that the diſtances of the bodies from each other, and from their common centre of gravity, are equal in equal times taken before and after the ſtroke; for in thoſe two caſes they move with equal velocities.

All the caſes of direct congreſs of two perfectly elaſtic bodies are delineated in the figures 11, 12, 13, 14, 15, 16, 17, 18, and 19, in which A and B repreſent the two bodies; C is their common centre of gravity, D the place where they meet. A D expreſſes the velocity of A, B D the velocity of B, and C D that of the centre of gravity. Hence by inſpecting the figures it will be eaſily diſcerned when both the bodies are in motion, or one of them is at reſt; alſo their directions, &c. Then the rule for determining the velocities after the ſtroke is as follows:—Take a point E in the line A B, produced if neceſſary, ſo that the diſtance C E be equal to C D; then, after the ſtroke, the right line E A will expreſs the velocity of the body A from E towards A, and the right line E B will expreſs the velocity of B from E towards B.

In *fig.* 11, B is larger than A, (which is plainly indicated by the ſituation of the centre of gravity C), B is at reſt, and A ſtrikes againſt it. In this caſe, after the ſtroke, both the bodies will recede from the point D, with the velocities E A and E B.

In *fig.* 12, A, the larger body, runs againſt the body B, which is at reſt. In *fig.* 13, the body A is larger than B, and they are both in motion the ſame way. In *fig.* 14, A is leſs than B; the reſt as in the preceding caſe. In *fig.* 15, A and B meet at D, where A remains at reſt. In *fig.* 16, A and B are equal, and after the ſtroke they recede with interchanged velocities. In *fig.* 17, the bodies are proportional to their velocities; hence the points C, F, D, and E, coincide. In *fig.* 18, A remains ſtationary at the place of congreſs D. Laſtly, in *fig.* 19, though the bodies A and B meet at D between the points A and B, yet after the ſtroke they both move towards F.

The numerical computation of thoſe caſes may be eaſily comprehended by the following example, which is adapted to the caſe of *fig.* 13.

A and B are two elaſtic bodies. A weighs 2 lb., and moves at the rate of 8 feet per ſecond. B weighs 1 lb., and moves the ſame way at the rate of 5 feet per ſecond. The diſtance A B is 12 feet.

1. To find the place of the centre of gravity C, we have $A + B : B :: AB : CA$; *viz.* $3 : 1 :: 12 : 4$; ſo that $AC = 4$, and $CB = AB - AC = 8$.

2. To find the diſtance BD, put $BD = x$; and ſince the diſtances A D and B D are run over in the ſame time, the former at the rate of 8, and the latter at the rate of 5 feet per ſecond; therefore we have $\frac{x}{5} = \frac{x + 12}{8}$: hence $8x = 5x + 60$; and $3x = 60$; or $x = 20 = BD$.

3. If the diſtance B D; *viz.* 20, be divided by the velocity of B (*viz.* by 5); the quotient 4, is the number of ſeconds, during which the bodies moved from their reſpective places A and B, to the place of their congreſs D.

4. $EC = CD = CB + BD = 8 + 20 = 28$; and $EA = EC - AC = 28 - 4 = 24$; which being divided by 4 (the number of ſeconds found above) gives 6 for the velocity of A after the ſtroke, in the direction from E towards A. Alſo $EB = EC + CB = 28 + 8 = 36$; which being divided by 4 (the number of ſeconds, &c.) gives 9 for the velocity of B after the ſtroke in the direction from E towards B. So that after the ſtroke, the bodies A and B will both continue to move the ſame way, but the former at the rate of 6, and the latter at the rate of 9 feet per ſecond.

It is now neceſſary to apply the above theory to thoſe caſes which really occur in nature, and in the firſt, ſince all known bodies are partially elaſtic, we muſt ſhew how to eſtimate the reſults of the colliſion of ſuch bodies. Thus, let A and B, *figs.* 20 and 21, be two bodies imperfectly elaſtic, C their common centre of gravity and D the place of their meeting. Divide AC in *a*, ſo that AC may be to *a*C, as the force compreſſing the body, A, is to the force whereby it reſtores itſelf. Alſo divide BC in *b*; ſo that BC may be to *b*C as the force compreſſing the body B is to the force whereby it reſtores itſelf. Take CE equal to CD; then the right line E*a* will expreſs the velocity of A after the ſtroke in the direction from E towards *a*, and the right line E*b* will expreſs the velocity of B after the ſtroke in the direction from E towards D.

In the foregoing paragraphs the diſtances have been reckoned from the centres of the bodies; but ſince the bodies muſt ſtrike with their ſurfaces, and not with the centres, therefore, when great accuracy is required, the thickneſſes of the bodies muſt be deducted from the diſtances. However, when the diſtances are conſiderable, and the ſizes of the bodies proportionately very ſmall, it is immaterial whether the diſtances be reckoned from the centres or from the ſurfaces of the bodies; the difference becoming inſignificant.

When more than two bodies move in the ſame ſtraight line, the computation of the velocity of each body after the various ſtrokes cannot be expreſſed under any general rules; the variety of caſes being too great, and often very intricate: yet when any particular caſe preſents itſelf, the preceding rules will be found ſufficient to determine the particulars; obſerving to apply the computation to the two bodies which, from the circumſtances of the caſe, appear to ſtrike firſt, then to one of thoſe and the next, and ſo forth. But ſometimes the equality of the bodies, their being contiguous to each other, and other favourable particulars, render the calculation pretty eaſy and obvious. Thus, if any number of equal and perfectly elaſtic bodies lie at reſt, contiguous to each other in the ſame ſtraight line, and another body, equal to one of them, ſtrike the firſt of them in the ſame ſtraight line, with any velocity; then after the ſtroke the ſtriking body and all the reſt will remain motionleſs, and the laſt body only will move on with the velocity of the ſtriking body.

If the movements, inſtead of being equable, as we have hitherto ſuppoſed, be either accelerated or retarded, the momentum for each ſingle ſmall portion of time, muſt be reckoned ſuch as belongs to the velocity acquired at that particular moment. In curvilinear movements, the direction of the motion in each point is the ſame as that of the tangent to the curve at that point. Laſtly, if the movements, either accelerated or retarded, be likewiſe curvilinear (as in the vibration of pendulums;) the momentum for each ſingle point muſt be deduced from the degree of acceleration and from the direction of the tangent, at that particular point.

Hitherto we have conſidered the colliſion of bodies, which ſtrike directly againſt each other; that is, in a direction perpendicular to their ſurfaces, and in the direction of their centres. It is now neceſſary to treat of oblique colliſion; for which purpoſe the doctrine of the compoſition and reſolution of forces, or of movements, muſt be previouſly known. See *Compoſition and reſolution of* FORCES.

THEOREM VI.

If a body, perfectly elaſtic, as A, fig. 22, *ſtrike obliquely at* C *on the firm obſtacle* B F, *then, after the ſtroke, this body will be reflected from that obſtacle in the direction* C E, *in ſuch a manner as to form the angle of reflection* E C F, *equal to the angle of incidence* A C B.

The oblique force, A C, being reſolved into two forces, *viz.* D C perpendicular to the obſtacle, and A D parallel to it; the effect on the plane is the ſame as if the body had advanced towards it directly from D, and (according to the laws already ſtated) the body A, after the ſtroke, would be ſent back in the direction C D. But of the two forces into which the original force of A was reſolved, this body retains the one repreſented by A D, ſince this force was not concerned in ſtriking the obſtacle; therefore, after the ſtroke, the body, A, is actuated by two forces, *viz.* one repreſented by C D, equal to A B, equal to E F; and the other repreſented by C F, equal to D A, equal to D E; hence it muſt move in the diagonal C E; and ſince the lines C F, F E, are reſpectively equal to the lines C B, B A, and the angles at B and F are equal, being right angles; therefore the triangle, E F C, is in every reſpect equal to the triangle A C B; conſequently the angle of reflection, E C F, is equal to the angle of incidence A C B.

It evidently follows, from this propoſition, that the force of an oblique ſtroke is to that of the ſame ſtroke coming in a perpendicular direction, as the ſine of the angle of incidence is to radius.

If the body, inſtead of ſtriking upon a plane ſtrikes upon a curve ſurface, the effect is the ſame as if it ſtruck on a plane, tangent to that ſurface at the ſtriking point.

This being premiſed, the application of the foregoing rules to the oblique colliſion of bodies will be illuſtrated by the following examples.

Let two non-elaſtic bodies A and B, *fig.* 23, move, the former in the direction A C, the latter in the direction B D, and let them meet at C D. Draw the line, M G, through their centres, and through the point of contact. From A and B, *viz.* the original ſituation of thoſe bodies, drop A M and B N perpendicular on M G. Then the force of each body may be reſolved into two forces, *viz.* that of A into A M and M C; and that of B into B N and N D. Of its two forces, A retains the force A M, whilſt M C is exerted againſt the other body. Of the two forces of the body B, the force B N is retained by it, whilſt the force N D is exerted againſt the other body. Therefore, the actions of thoſe bodies upon each other is exactly the ſame as if they moved directly one from M and the other from N; hence the above ſtated rules of direct colliſion, will ſerve to find out whether the bodies, after the ſtroke, will proceed both the ſame way, or different ways, and at what rate. But when their velocities have been thus determined; for inſtance, if it be found, that had the bodies moved directly from M and N after the ſtroke, the body, A, would have moved as far as O, whilſt the body, B, would have moved as far as G; then it muſt be recollected, that, in the preſent caſe of oblique colliſion, the body, A, has retained the force A M; therefore, after the ſtroke, the body, A, is actuated by two forces, *viz.* one equal and parallel to A M, and another which is equal and parallel to C O, in conſequence of which this body muſt run a compound courſe, which is found thus: Through the centre, C, draw C I equal and parallel to A M; through I, draw I E equal and parallel to C O, then the diagonal C E exhibits the velocity and the direction of the body, A, after the oblique concourſe. With reſpect to the body, B, it has been ſaid, that at the concourſe this body retains the force B N, and that, if the bodies had moved directly towards each other, B would, after the ſtroke, have moved from D to G. Therefore, through D draw D H equal and parallel to B N, and through H draw H F equal and parallel to D G; and, laſtly, the diagonal, D F, will repreſent the velocity and the direction of the body, B, after the oblique concourſe.

If the bodies be perfectly elaſtic, then ſuppoſe it be found (by the rules for elaſtic bodies) that, after the ſuppoſed direct concourſe, the body, A, would have been ſent back to Q, in the ſame time that B would have been ſent back to R; it follows, that after the oblique ſtroke, the body, A, will be actuated by two forces, *viz.* one equal and parallel to A M, and the other equal and parallel to C Q. The body, B, will likewiſe be actuated by two forces, *viz.* one equal and parallel to B N, and the other equal and parallel to D R; therefore, in *fig.* 24, draw Q Z through Q, equal and parallel to A M; alſo through Z draw I Z equal and parallel to C Q; then the diagonal, C Z, repreſents the direction and the velocity of the elaſtic body, A, after the oblique ſtroke.—Again, through R draw the line, R X, equal and parallel to B N, and through X draw the line, X Y, equal and parallel to D R, then the diagonal, D X, will repreſent the velocity and the direction of the elaſtic body, B, after the oblique ſtroke.

Amongſt all the caſes of colliſion, we have hitherto omitted to mention the ſtriking of a body upon an immoveable obſtacle. This has been done merely becauſe the particulars belonging to it may be eaſily derived from the conſideration of the foregoing caſes; it being only neceſſary to conſider this caſe as if it were that of the colliſion of two bodies, either elaſtic or non-elaſtic, or partially ſo, and to ſuppoſe that one of the bodies, which repreſents the immoveable obſtacle, is infinitely great.

There is a difference between the ſtroke of an elaſtic body, and that of a non-elaſtic one, which, not being very obvious, deſerves to be mentioned. This is, that the effect of the blow of an elaſtic body upon another body, as upon a plane, is double to that of a non-elaſtic body, their maſſes and velocities being equal. This ariſes from the elaſticity of the former, which, after the ſtroke, by endeavouring to recover its original figure, acts upon the plane with a force equal to the firſt impreſſion; whereas a non-elaſtic body acts only with the firſt impreſſion. See the article PERCUSSION. Alſo, if the reader wiſh to ſee the original inveſtigation of the laws belonging to the colliſion of bodies, together with any analytical and experimental illuſtration of the ſame, he may peruſe Dr. Wallis's paper in the Phil. Tranſ. No. 43; Mr. Huygens's paper, Phil. Tranſ. No. 46; ſir Chriſt. Wren's paper, Phil. Tranſ. No. 43; Graveſande's Mat. Elem. of Nat. Phil. edited by Deſaguliers; Gregory's Mechanics, vol. i. chap. v.; and all the beſt works on mechanics.

COLLIUS, PETER, in *Biography*, of the college of Milan, flouriſhed in the beginning of the ſeventeenth century, and was the author of a curious treatiſe entitled "De Animalibus Paganorum," printed at Milan in two vols. 4to. in the years 1622-3. In this work he decides without heſitation on the future happineſs or miſery of many virtuous and truly illuſtrious characters of the Pagan world. His concluſions were founded on conjectures, deduced from a comparative view of their means of divine knowledge, their lives and manners, their opinions and writings, united with the teſtimony of ſacred and profane hiſtory. He publiſhed alſo a treatiſe "De ſanguine Chriſti," and a quarto volume entitled "Concluſiones Theologicæ." In them all is a great diſplay of ſingularity, accompanied with a good ſhare of talents. Nouv. Dict. Hiſt.

COLLIWILY, in *Geography*, a town of the iſland of Ceylon; 50 miles W. of Trincomaly.

COLLMEN, or CULLMEN, a town of Germany, in the circle of Upper Saxony, and circle of Leipſick; 6 miles E.N.E. of Mutſchen.

COLLOBRIERES, a town of France, in the department of the Var, and chief place of a canton, in the diſtrict of Toulon; 18 miles N.E. of Toulon. The place contains 1509, and the canton 2933 inhabitants: the territory includes 322½ kilometres, and two communes.

COLLOCOCCUS, in *Botany*, Sloan. See CORDIA *Collococca*.

COLLON, in *Geography*, a poſt and fair town of the county of Louth, Ireland, which is neat and well built; and which has improved conſiderably under the auſpices of the late lord chief baron Foſter, and his ſon the right honourable John Foſter, the much reſpected ſpeaker of the Iriſh houſe of commons, when the union took place. It is 29 Iriſh miles N. from Dublin.

COLLONGE, a town of France, in the department of Lèman, and chief place of a canton, in the diſtrict of Genève; the place contains 1178, and the canton 8947 inhabitants: the territory comprehends 212½ kiliometres, and nine communes.

COLLOPS, in *Ancient Geography*, an appellation diſtinguiſhing two towns of Africa; the one called "Collops Parva," appears to have been the ſame with *Cullucitanæ*, ſituate E. of the Sinus Numidicus; the other, called "Collops Magna," was, according to Ptolemy, the ſame with *Cullu*, and ſituated N.W. of the ſame gulf.

COLLOQUIA, in *Eccleſiaſtical Hiſtory*, a name given in Swiſſerland to aſſemblies of the proteſtant Griſon clergy. Each league is divided into a certain number of diſtricts, the miniſters of which aſſemble twice every year; and theſe aſſemblies are called *colloquia*. Each colloquium has its preſident, and each league a ſuperintendent, called a dean. The ſupreme authority in ſpiritual concerns is veſted in the ſynod, which is compoſed of the three deans, and the clergy of each league; the ſynod aſſembles every year alternately in each of the three leagues. Candidates for holy orders are examined before the ſynod. The neceſſary qualification for admiſſion into the church, ought to be the knowledge of Hebrew, Greek, and Latin; but many are ordained without the leaſt acquaintance with either of theſe languages. Formerly Latin was ſolely uſed, as well in the debates of the ſynod, as for the purpoſe of examining the candidates; but at preſent that tongue is more and more diſuſed, and German is employed in its ſtead. See Grisons.

COLLOQUIUM, in *Law, (a colloquendo)*, a talking together, or affirming of a thing, laid in declarations for words in actions of ſlander, &c.

COLLUCIANISTÆ, in *Church Hiſtory*, a deſignation given to the Arians, from the martyr Lucian, a preſbyter of Antioch.

COLLUM, in *Anatomy*. See Neck, and Cervix.

COLLURIO, in *Ornithology*, the name given by Briſſon to the *Lanius Collurio* of the Linnæan *Fauna Suecica;* red backed ſhrike of Engliſh writers.

Collurio *madagaſcarienſis*, of Briſſon, the hook-billed ſhrike, *lanius curviroſtris*.

COLLUSION, a ſecret underſtanding between two parties, who plead, or proceed, fraudulently againſt each other, to the prejudice of a third. This colluſion is either apparent, when it ſhows itſelf on the face of the act; or more commonly, it is ſecret and artfully concealed by a ſhow of honeſty. This is a practice which the law abhors; and, therefore, when detected, it makes void all things dependent upon it, though otherwiſe in themſelves good. Co. Litt. 109, 360. Plowd. 54. Colluſion may ſometimes be tried in the ſame action, wherein the covin is, and ſometimes in another action, as for lands aliened in mortmain by a *quale jus;* and where it is apparent, the proof of it is unneceſſary; but when it is ſecret, it muſt be proved by witneſſes, and found by a jury like other matters of fact. 9 Rep. 33. The ſtatute of Weſtm. 2. 13 Ed. I. c. 33. gives the writ *quale jus*, and inquiry in theſe caſes; and there are ſeveral other ſtatutes relating to deeds, made by colluſion and fraud. The caſes particularly mentioned by the ſtatute of Weſtm. 2. are of *quare impedit*, *aſſiſe*, &c. which one corporation brings againſt another, with intent to recover the land or advowſon, for which the writ is brought, held in mortmain, &c. See Fraud.

In the canon law, colluſion, in matters of benefices, vacates the benefice, and incapacitates the perſon from holding any benefice at all.

COLLUTHIANS, in *Eccleſiaſtical Hiſtory*, a religious ſect, which roſe about the beginning of the fourth century; on occaſion of the indulgence ſhewn to Arius by Alexander, patriarch of Alexandria.

Several people being ſcandalized at ſo much condeſcenſion; and, among the reſt, Colluthus, a prieſt of the ſame city; he hence took a pretence for holding ſeparate aſſemblies, and by degrees proceeded to the ordination of prieſts, as if he had been a biſhop; pretending a neceſſity for this authority, in order to oppoſe Arius. To his ſchiſm he added hereſy; teaching, that God did not create the wicked; that he was not author of the evils that befal men, &c.—He was condemned by a council held at Alexandria by Oſius, in the year 330.

COLLUTHUS, in *Biography*, a preſbyter of Alexandria, was founder of the temporary Chriſtian ſect, at the beginning of the fourth century, above-mentioned. By the decrees of the council held by Oſius, Colluthus was deſpoiled of the epiſcopal honours with which he had inveſted himſelf, and the preſbyters whom he had ordained were degraded. Colluthus ſubmitted to the decree, and returned quietly to the duties of his office as a parochial preſbyter; his followers likewiſe re-united themſelves to the orthodox church. Nouv. Dict. Hiſt.

COLLUTION, *Collutio*, in *Medical Writers*, is ſometimes uſed for the waſhing of the mouth, particularly, when done to clean or faſten bad or looſe teeth; or free the gums, &c. from ulcers.

COLLUVIES, a term which Calcott and other writers on the univerſal deluge have applied to the fluid maſs, into which, according to their opinion, the ſtrata of the antediluvian earth were diſſolved, and their conſtituent corpuſcles ſeparated. See Deluge.

COLLYBUS, Κολλυϐος, in *Antiquity*, the ſame with what is now called the rate of exchange.

COLLYRÆ, or Collyrides, a certain ornament of hair, worn by women on their necks. It was made up in the form of the ſmall, roundiſh, cakes, called κολλυραι, *collyræ*.

COLLYRIDIANS, in *Church Hiſtory*, a ſect, towards the cloſe of the fourth century, denominated from a little cake, called by the Greeks κολλυριδιαι, *collyridia*, which they offered to the Virgin Mary.

This ſect, it ſeems, conſiſted chiefly of Arabian women, who brought it from Thrace to Arabia, and who, out of an extravagance of devotion to the Virgin, met on a certain day in the year, to celebrate a ſolemn feaſt, and to render divine honours to Mary as to a goddeſs; eating the cake which they offered in her name.—St. Epiphanius, who relates the hiſtory of this ſuperſtitious ceremony, ridicules it. They ſprung up in oppoſition to the Antidico-Marianites.

COLLYRIUM, κολλυριον. This term was formerly applied, to any medicament, ſolid, or liquid, employed to reſtrain defluxions; but it is now entirely confined to wet applications, topically applied for this purpoſe in complaints of the eyes.

Collyrium is alſo a name given to unguents uſed for the ſame purpoſe; as unguent of tutty, and ſeveral others.

Collyrium is alſo a denomination given, though improperly, to ſome liquid medicines uſed againſt venereal ulcers.

Collyrium *Samium*. See Samia *terra*.

COLLY-WESTON *Slate*, a whitiſh kind of micaceous grit ſtone, which ſplits into very thin lamina, and is much uſed for ſlating of buildings in the eaſtern and ſome of the midland counties of England; it is the produce of a ſtratum ſituated not far in the ſeries from the Oalite or Ketton ſtone, ſo well known to builders. In this ſtratum, particularly near Stonesfield, in Oxfordſhire, bones of animals of ſome unknown kind are frequently found lodged. See Slate.

COLM, in *Geography*, a ſmall iſland of Scotland, in the Frith of Forth, ſix miles S.E. of Dumferline.

COLMAN, George, in *Biography*, an Engliſh writer, was the ſon of Mr. Thomas Colman, Britiſh reſident at the court of the duke of Tuſcany. He was born at Florence about the year 1733. He received his ſchool education at Weſtminſter; and was entered as ſtudent at Chriſt-church, Oxford, where he engaged with Bonnel Thornton, in writing "the Connoiſſeur," a periodical paper of conſiderable merit, which was afterwards publiſhed in four volumes, 12mo. This work is remarkable for the humorous delineations of the manners of the age, and diſplays claſſical reading and taſte. On leaving the univerſity he entered at Lincoln's Inn, and was in due courſe called to the bar, but never followed his profeſſion. In 1760, he produced two dramatic pieces which were received with great ſucceſs, the firſt was entitled, "Polly Honeycombe," and the other "the Jealous Wife;" this laſt ſtill keeps its place on the ſtage. In 1764, lord Bath died and left Mr. Colman a handſome annuity, which was increaſed on the death of general Pulteney, in the year 1767. In conjunction with Garrick, he brought out the "Clandeſtine Marriage," a comedy of great merit, and which maintains an undiminiſhed reputation. In 1768, he purchaſed a ſhare of the Covent Garden theatre; this, however, he ſoon diſpoſed of, and purchaſed Mr. Foote's theatre in the Haymarket, which he held till his death in 1794, though he had for the five preceding years been incapable of any buſineſs, owing to a paralytic ſtroke with which he was ſeized in 1789, and which affected his underſtanding in ſuch a manner as to bring on derangement and idiocy. Mr. Colman tranſlated Terence's plays into a ſort of blank verſe: alſo "Horace's Art of Poetry," which added to his reputation as a claſſical ſcholar. In 1787, he collected, in three ſmall volumes, a variety of pieces which he had publiſhed at different times, under the title of "Proſe on ſeveral occaſions, accompanied with ſome pieces of verſe." Gen. Biog.

COLMAR, in *Geography*, a town of Germany, in the duchy of Holſtein, five miles S.E. of Gluckſtadt.

Colmar, a large and well built town of France, and capital of the department of the Upper Rhine, ſeated on the river Fecht, and ſurrounded by a wall, flanked with towers. It has a prefect and four courts of juſtice. The town contains 13,396, and the canton 14,429 inhabitants; the territory includes 55 kiliometres, and two communes; $10\frac{1}{2}$ leagues N. of Bâle. The principal trade of the inhabitants of Colmar, who are ſaid to be very induſtrious, is in corn, and wine; and their chief manufactures are thoſe of woollen cloth. callico prints, ſtockings, hardware, and gun-powder. The diſtrict conſiſts of 142 communes or townſhips, diſtributed into 13 cantons, and comprehending a population of 144,821 inhabitants. Its whole territory includes 1680 kiliometres. It has ſilver, copper, lead, antimony, arſenic, and beautiful cryſtal mines; and alſo a manufacture of gold and lace. N. lat. 48° 4′ 44″. E. long. 7° 22′ 11″.

COLMARS, a town of France, in the department of the Lower Alps, and chief place of a canton, in the diſtrict of Caſtillane; 22 miles N. of it. The place contains 898, and the canton 3585 inhabitants; the territory includes 285 kiliometres and five communes.

COLMBERG, or Kolbenberg, a town of Germany, in the circle of Franconia, and principality of Anſpach; 9 miles N.W. of it.

COLME, La, a river of France, branching from the river, Aa, at Watte, in the department of the ſtraits of Calais.

COLMENAR, a town of Spain, in Old Caſtile, on the confines of New Caſtile; 7 leagues N.W. of Talavera de la Reina.—Alſo, a town of Spain in New Caſtile, five leagues N.E. of Eſcurial.

COLMITZ, a town of Germany, in the archduchy of Auſtria, four miles S.S.W. of Droſſendorf.

COLMWORTH, a rectory in the county of Bedford, and hundred of Barford: the lofty ſpire of its ſteeple forms a very conſpicuous object to the ſurrounding country. In the Government Trigonometrical Survey in 1799, its ſituation was determined by obſervations from Lilley-Hoe ſtation, diſtant 97,617 feet, and bearing 0° 12′ 52″ S.E. from the parallel to the meridian of Greenwich; and from Lidlington ſtation 75,944 feet; whence is deduced its latitude 52° 12′ 49″.3 N. and its longitude 22′ 27″, or 1^m $29^s.8$ W. of Greenwich.

COLN, a river of England, which paſſes by Uxbridge and Colnbrook, and runs into the Thames, near Staines, ſeparating the county of Middleſex from Buckinghamſhire. The clearneſs and purity of the water of this river, iſſuing almoſt entirely in ſprings out of the chalk hills of Hertfordſhire, have always been proverbial. This circumſtance probably occaſioned the cutting, at ſome diſtant periods, of two channels many miles in length, for diverting part of its waters acroſs Hownſlow-heath to Twickenham, and into Buſhey-park; and a very principal part of the deſign of the Paddington branch of the Grand Junction Canal, in latter times, was for diverting part of its limpid ſtreams, in order to ſupply the metropolis with water, to which purpoſe it is admirably adapted.

Coln, a river of Eſſex, which is navigable from the mouth of the Thames at Merſey iſland up to the town of Colcheſter. See Canal.

Coln, a river which runs into the Thames at Cricklade.

COLNBROOK, a town of England, in the county of Bucks, on the river Coln, with a weekly market on Wedneſday, three miles E. of Windſor, and 17 W. from London.

COLNE, a conſiderable market-town of Lancaſhire, England, is advantageouſly ſituated on a dry and elevated ridge. This place, ſays Dr. Whitaker, "is unqueſtionably the *colunio* of the anonymous Ravennes, and was probably never abandoned entirely, in the long and obſcure period of Saxon hiſtory." At this place, there have been ſeveral Roman coins, and other antiquities found. The church is a ſpacious ſtructure, and appears to have been "reſtored about the time of Henry VII or VIII." Here are a market on Wedneſday, and two annual fairs. Colne is 218 miles N. of London, and contains 782 houſes, with 3626 inhabitants. This town is ſituated in the hundred of Blackburn, near to the grand ridge on its weſtern ſide, and alſo to the Leeds and Liverpool canal, and to the famous Foulridge tunnel upon it. It was once an object of contemplation to conduct a branch of the Rochdale canal to this town; but it was never accompliſhed. Whitaker's Hiſtory of Whalley, 4to. See Canal.

COLNUD, *de Cayenne*, of Buffon, in *Ornithology*, the bare-necked crow, *corvus nudus*.

COLOMBAUDE, the name given by Buffon to *motacilla atricapilla*, or black cap.

COLO, in *Geography*, a town of Poland, in the palatinate of Kaliſch, 20 miles N. of Kaliſch.

Colo, in *Ancient Geography*, a Roman colony, near the city of Conſtantina, in the kingdom of Algiers, in Africa; the ruins of it now remain, having a caſtle on a very high rock towards the ſea-coaſt, with a garriſon, under the command of an aga; under the protection of which is a ſmall French factory, that deals with the Moors for hides, wax, and wool. The mountains of Colo abound with a large and fierce kind of monkeys, which the Moors have the art of catching with great facility.

COLOBI, a people of Africa, placed by Ptolemy in the Troglodytic territory.

COLOBIUM, [illegible]ον, from κολοω, *I mutilate*, among the *Ancients*, an upper garment, without ſleeves, longer than the tun[illegible]

COLOBOMA, in *Medical Writers*, is uſed for the preternatural growing together of the lips, or eyelids, or for the adheſion of the ears to the head.

COLOBON Promontorium, in *Ancient Geography*, a promontory of Ethiopia, near Egypt, placed by Strabo and Ptolemy in the Arabic gulf.

COLOBONA, a town of Spain, in Bætica, placed by Pliny in the diſtrict of Hiſpalis: now Trebuxena.

COLOBRASUS, a town of Aſia, ſituate in the interior part of Cilicia Montana, which, according to Ptolemy, was a country of Pamphylia.

COLOCASIA, in *Botany*, Cluſ. See Arum *Colocaſia*.

COLOCASITES, in *Ancient Geography*, an iſland of the Red ſea, on the coaſt of Azania, a country of Ethiopia, according to Pliny.

COLOCOLO, in *Ornithology*, a name given by the people of the Philippine iſlands, to a bird called alſo there *caſſili*, and by ſome authors the *water raven*, corvus fluviatilis. This bird, as it is deſcribed in the Philoſophical Tranſactions (n. 285.) "is of the ſhape of a common raven, but is truly an amphibious bird, living more of its time under water than in the air; it is black in colour; its neck is remarkably long, and it feeds on fiſh, which it hunts under water, as they do one another; it feeds likewiſe on frogs, ſerpents, and ſhell-fiſh. It is common to ſee it under water in clear rivers, where it ſeems perfectly at eaſe, and runs about with great ſwiftneſs; at times it comes up to the ſurface, and dries its wings in the air and ſunſhine." It is underſtood by naturaliſts pretty generally, that the colocolo of the Philippines is no other than the common corvorant, *pelecanus carbo*, a bird known to inhabit moſt parts of the world, and to delight eſpecially in maritime ſituations, or in marſhes, and other watery places. near the ſea-coaſt.

COLOCYNTHIS, Coloquintida, *Bitter Apple*, in the *Materia Medica*. The colocynth is a ſpecies of gourd (*cucumis colocynthis*, Linn.) brought from Aleppo and Cyprus, of a globular ſhape, about the ſize of the fiſt, white, ſmooth, of a fungous texture, divided internally into large cells, which contain a number of oblong ſeeds.

The pulp, which is the part uſed medicinally, is intenſely bitter, nauſeous, and acrid. It contains a remarkably large portion of mucilage, ſo as to render ſlimy a conſiderable quantity of water when boiled with it; and, on this account too, the ſpirituous tincture is too thick to paſs through a paper filter.

The colocynth, taken in ſubſtance, without any mixture or preparation, is one of the moſt violent purgatives that we are acquainted with, producing, when in a large doſe (that is, when more than eight or ten grains), very ſevere griping pains, and often a diſcharge of blood, and leaving for ſome days ſymptoms reſembling thoſe of dyſentery. It is ſaid, too, to act upon the bowels when applied externally to the abdomen.

The activity of the colocynth renders it a valuable medicine, when uſed with caution. It is ſeldom or never employed by itſelf, but is mixed with aloes, and other purgatives, and much adds to their efficacy.

The only preparation of it retained in the London Pharmacopœia, is the extract (*extractum colocynthidis compoſitum olim ext. catharticum*), which is prepared by digeſting in proof ſpirit, colocynth, aloes, ſcammony, and cardamom ſeeds, and afterwards evaporating the tincture to the proper conſiſtence. This is one of the moſt certain and powerful purgatives we are acquainted with, and generally operates without much griping or inconvenience. It may be properly combined with calomel, if neceſſary, or, in caſes of ſpaſmodic pain of the bowels, with opium.

Colocynthis, in *Botany*. Tourn. Bauh. Pin. Ray. Moris. See Cucumis *colocynthis*.—Plum. See Trichosanthes *amara*.

COLOCZA, in *Geography*, a town of Hungary, on the Danube, the ſee of an archbiſhop. This was formerly an important place, but it is now ſunk into decay, in conſequence of repeated wars; 136 miles S.E. of Vienna. N. lat. 46° 33′. E. long. 18° 36′.

COLODI, a town of Italy, in the republic of Lucca; 7 miles from Lucca.

COLOE, in *Ancient Geography*, a marſh of Ethiopia, according to Ptolemy, which, he ſays, was the ſource of the river Aſtapus.—Alſo, a town, ſituated, according to Ptolemy, in the interior of Ethiopia; but, according to Arrian, it was a maritime town, and carried on a conſiderable commerce in ivory.

COLOEPHRYGES, a people of Greece, in Bæotia, called alſo *Anticondyles*, according to Steph-Byz.

COLOEPHRYX Mons, a mountain of Bæotia. Heſychius.

COLOES, *Enli-Gheul*, a lake of Aſia Minor, in Lydia, according to Strabo; called *Gigæa* by Homer. It was two leagues, or 40 ſtadia, to the N.E. of Sardes. Diana, ſurnamed *Coloëne*, had a temple on the bank of this lake, ſurrounded by the tombs of the kings of Lydia, and, among others, that of Aliattes, deſcribed by Herodotus, and compared by him with the grandeſt works of the Babylonians and Egyptians.

COLOGENBAR, a town of Aſia, ſituate near the Euphrates, and the town of Edeſſa.

COLOGNA, in *Geography*, a town of Italy, in the Paduan; 15 miles from Vicenza.

COLOGNE, Peter De, in *Biography*, a proteſtant miniſter at Metz, in the 16th century. He was born at Ghent, and educated at Paris, from whence, at the advice of Robert Stevens, he retired to Geneva, to avail himſelf of the inſtructions of John Calvin, who perſuaded him to devote his life to the work of the miniſtry. He embarked in the proteſtant cauſe with great zeal and ardour, and the ſuperiority of his talents above thoſe of his contemporaries, recommended him to the peculiar friendſhip of Calvin and Beza. He commenced his miniſterial functions at Metz, in the year 1558, where he continued in the exerciſe of them either openly, or from houſe to houſe, in a private way, during the reigns of Francis II. and Charles IX. In the performance of his duty, he was occaſionally ſubjected to the miſeries of impriſonment and exile, until the diſperſion of the proteſtant church at Metz, in 1659. From this town he went to Heidelberg, where he undertook the charge of a congregation, and where he died while he was a young man. He was the author of ſome original works, and tranſlated others from the German into the French language, but, as they were moſtly on temporary ſubjects, it is not neceſſary to enumerate them. Nouv. Dict. Hiſt.

Cologne, in *Geography*, an archi-epiſcopal electorate of Germany, in the circle of the Lower Rhine, divided into ſeveral diſtricts by other eſtates, and deriving its name from the city of Cologne. It was a biſhopric in the year 314, and, in 799, was erected into an archbiſhopric by Charlemagne. In the ancient conſtitution of Germany, the archbiſhop aſſumed the title of born legate of the holy ſee, and arch-chancellor of the ſacred empire for Italy. He gave his vote after the elector of Treves, and ſat at the right hand of the emperor, at aſſemblies held in his own dioceſe, in Gaul, or in Italy. The metropolitan church, and chapter, which is compoſed of 25 canons, and 36 dignitaries, are at Cologne. Since the French revolution, and the ſubſequent arrangement of its territories, Cologne is a diſtrict of Roer, or Roor, comprehending 10 cantons, *viz.* Cologne, Bergheim, Bruhl, Dormagen, Elſen, Juliers, Kerpen, Lechnich, Wayden, Zulpich, which include 294 communes, 1375 kilometres, and 137,215 inhabitants. Although this electorate is reckoned one of the moſt fertile countries of Europe, the bigotry, ignorance, and idleneſs of its inhabitants, who are moſtly Roman Catholics, prevent its deriving thoſe advantages from its productions, and particularly its commerce, which might reaſonably be expected.

Cologne, the capital of the archbiſhopric above mentioned, and formerly one of the free and imperial cities of Germany, in the circle of Weſtphalia. It was taken poſſeſſion of by the French in 1794, and is now the capital of the diſtrict that bears its name in the French department of Roer, and is ſaid to contain 38,844 inhabitants. Cologne is ſituated, in the form of a creſcent, on the banks of the Rhine, and fortified in the ancient manner; but its walls are in ſo decayed and tottering a ſtate, that they are incapable of affording it any defence. The whole of its length, along the river, is about 3½ miles, two-thirds of which ſpace is uninhabited; ſeveral of the ſquares and ſtreets more reſembling a field, or an uncultivated garden, than parts of an inhabited city. In traverſing its environs one may obſerve more than 150 miſerable farm-houſes, with gardens, which furniſh the city with all ſorts of greens, butter, cheeſe, milk, &c. The ſtreets are narrow, winding, and gloomy, and moſt of the houſes are very high, old, and ruinous; and yet this city is ſaid to contain, within its compaſs, more churches, chapels, and monaſteries, than there are days in the year. The Roman Catholic univerſity ſcarcely merits the appellation. The number of beggars that diſgrace its police is very great, and it is ſaid, that the propenſity to idleneſs, gluttony, and begging, which prevails through the city and adjacent country, is ſanctioned and encouraged by the example of the different orders of monks; whoſe chief object is to keep the people, who, with the exception of a few Proteſtant families, are Roman Catholics, in a ſtate of ignorance and ſuperſtition. Two thirds of the inhabitants are either profeſſed beggars, or eccleſiaſtics. The other third conſiſts of a few patricians, merchants, and mechanics, on the produce of whoſe exertions and induſtry the reſt live.

Cologne, upon the whole, is at leaſt two centuries behind the other parts of Germany, with regard to improvement in the arts and ſciences. Although no city in Germany is more favourably ſituated for commerce, the natural bigotry and idleneſs of the inhabitants lead them to forego the benefits which their ſituation affords them; and their trade has dwindled away to the manufacture of a few ribbands, ſtockings, lace, and tobacco. The veſſels that may be always ſeen in the port of Cologne are very numerous; the quay, more than 1½ mile long, is continually crowded with ſhips; but the goods on board are almoſt wholly the property of foreign merchants. About a fortnight before the fair at Frankfort begins, there is a great concourſe of theſe merchants at Cologne, who repair daily from thence to Frankfort, by means of two commodious veſſels containing from 150 to 200 paſſengers, which perform this voyage every other day during the fair. The Jews were expelled from Cologne in the year 1485, and from that remote period not one of them has ever obtained leave to ſettle there, or dared even to enter the city without permiſſion of the magiſtrate. Under the old police, if a Jew came into the city, he was accompanied by a guard during his ſtay, and obliged to pay a ducat for every hour of his continuance there. In the year 1618, the Proteſtants were alſo expelled, but ſome years after they obtained permiſſion to return. The magiſtrates indeed gave them leave to erect a place of worſhip, which was deſtroyed by the infatuated mob as ſoon as it was finiſhed. Since that event they have erected for themſelves ſeveral handſome churches at Mulheim, three miles from Cologne, on the right bank of the Rhine. The trifling commerce of Cologne has been confined to a few Proteſtant families ever ſince the period of their return, who, it is obſerved, are the only opulent inhabitants of the place. The wealth of the churches at Cologne, at leaſt before it was taken poſſeſſion of by its new occupiers, was immenſe, particularly that of the cathedral. Theſe churches are repoſitories of various relics that are held in high eſtimation by the ſuperſtitious catholics. The theatre is a roomy building, but not elegant. The town-houſe is an irregular ſtone edifice, aukward and in a ruinous ſtate. The arſenal occaſions part of a very narrow ſtreet; its contents are chiefly ancient arms, not proper for modern uſe; and the building itſelf is in a ſtate of decay. The dealers of Nuremberg and Augſburg bring their toys in large quantities to Cologne for exportation to Holland, England, and America. The Spaniards and Portugueſe carry on a very profitable trade with them in both the Indies. The inhabitants of Cologne derive a very conſiderable advantage from the importation of coals out of the adjacent countries of Berg, the electorate of Treves, the principalities of Saarbruck, and duchy of Deuxponts, which come by the Saar down the Moſelle and the Rhine, and ſupply the want of wood-fuel, that is very ſcarce about Cologne. Some of theſe coals are round and large, and another ſort conſiſts of duſt, which is mixed with clay and water, and formed into ſmall cakes, manufactured in ſummer; and which, being gradually hardened by the heat of the ſun, are ſtored up in large magazines erected for that purpoſe. Theſe coal-cakes are ſold at 12 ſtivers (about 1 *s.* Engliſh money) per hundred; and it is ſaid, that 100 of them will go as far as three buſhels. Near this city ſome pſeudo-volcanic remains have been traced, which are thought to be ſuch as are mentioned by Tacitus at the cloſe of the 13th book of his Annals, the effects of ſubterranean fire which ravaged the country of the Juhones. N. lat. 50° 55′ 21″. E. long. 6° 55′.

Cologne, a town of France, in the department of Gers, and chief place of a canton, in the diſtrict of Lombès; ſix leagues E. of Auch. The place contains 769, and the canton 6096 inhabitants; the territory comprehends 117½ kilometres, and 17 communes.

Cologne *Earth*, a ſubſtance uſed in painting, as a water colour, much approaching to amber in its ſtructure, and of a deep brown. It has generally been eſteemed a genuine earth, but has been diſcovered to contain a great deal of vegetable matter, and, indeed, it is a very ſingular ſubſtance.

It never conſtitutes an entire ſtratum in the earth, but is lodged among other ſtrata in large flat detached maſſes. It is moderately dry, while in the earth, and of a ſoft crumbly texture. When dried, it is of a deep, duſky brown, of a very cloſe, compact, and fine texture, and very remarkably light; it is of a ſmooth, even ſurface, dry, but not harſh to the touch, crumbles eaſily to pieces between the fingers, and ſlightly ſtains the hands; it adheres firmly to the tongue, but not at all reſembling the aſtringency of the boles, or any thing elſe of the mineral kingdom, but plainly reſembling the taſte of oak bark. It makes no efferveſcence with acids; if thrown into water, it ſwims on the ſurface, till thoroughly wetted; and if brought into contact with burning coals, it takes fire and burns of itſelf, till reduced to yellowiſh aſhes.

It is eaſy to diſcern from this account, that, though this is generally eſteemed an earth, and known to the world by no other name, it is no pure native foſſil, but contains more vegetable than mineral matter, and owes its origin to the remains of wood which has been long buried in the earth. It is dug in Germany and France; the quantities conſumed in painting, in London, are brought from Cologne, where it is found very plentifully; but our own kingdom is not without it, it being found near Birmingham, and on Mendip hills in Somerſetſhire; but what has been yet found there is not ſo pure or fine, as that imported from Cologne. Hill's Hiſt. of Foſſils. p. 64. and Da Coſta's Hiſt. of Foſſils, p. 121.

COLOGNOLI, in *Geography*, a town of Italy, in the duchy of Tuſcany; 6 miles E. of Leghorn.

COLOKITIA, or KOLOKITIA, a town of European Turkey, on the ſouthern coaſt of the Morea, in a gulf to which it gives name; 25 miles S.E. of Miſitra. N. lat. 36° 47′. E. long. 22° 34′.

COLOMAY, a town of Poland, in the palatinate of Red Ruſſia; 5 miles N.E. of Halecz.

COLOMBA, in the *Materia Medica*. See COLUMBO.

COLOMBEL, NICOLAS, in *Biography*, a French painter who was born in 1646, at Sotteville near Rouen, and became the ſcholar of Le Sueur, under whom he ſtudied ſeveral years; he then went to Italy, where he aſſiduouſly copied the works of Raffaelle and Nicolo Pouſſin; but though he enjoyed every advantage of education, and laboured to form his ſtyle upon the model of thoſe great maſters, the poverty of his genius ever appeared; and his pictures, though correctly drawn and carefully finiſhed, generally wanted that elevation of thought and ſtriking expreſſion, which can alone give value to hiſtoric painting. However, in 1682, he ſent four pictures which he had painted at Rome to Paris, and thereby gained ſufficient reputation to cauſe his being choſen a member of the Academy upon his return to Paris in 1694. One of his moſt eſteemed pictures is an "Orpheus playing on his Lyre," in the apartment of the menagerie in the royal palace. He died in the year 1717. D'Argenville.

COLOMBES, in *Geography*, a town of France, in the department of Paris, and chief place of a canton, in the diſtrict of St. Denys; 1½ league N.W. of Paris.

COLOMBEY, a town of France, in the department of the Meurthe, and chief place of a canton, in the diſtrict of Toul; 15 miles S.W. of Nancy. The place contains 858 and the canton 12,887 inhabitants; the territory includes 315 kiliometres and 32 communes.

COLOMBIEN, DE, in *Biography*. See VALENTINE.

COLOMBIER, in *Geography*, a town of France, in the department of the Upper Saone, and chief place of a canton, in the diſtrict of Veſoul; four miles N. E. of Veſoul.

COLOMBIER, a town of Swiſſerland, in the principality of Neuchatel; two miles S.W. of Neuchatel.

COLOMBIERE, CLAUDE DE LA, in *Biography*, a celebrated French jeſuit, was born near Lyons, in which city he proſecuted his ſtudies, devoting moſt of his time to rhetoric and theology. Of the former branch of ſcience he became a profeſſor, and in the latter he was diſtinguiſhed as a popular and impreſſive preacher. In this character he was noticed at the court of the duke of York, afterwards James II. of England, being made chaplain and confeſſor to the ducheſs, until he was baniſhed under ſuſpicion of being engaged in a conſpiracy. He returned to his native country in the year 1682,, where he died at the age of 41. Colombiere publiſhed ſix volumes of ſermons, which are elegant, pious, and ſimple; they have been often reprinted. He publiſhed alſo a "Collection of Orations" in Latin, delivered by the author as profeſſor of rhetoric; a volume of "Moral Reflections;" two volumes of "Spiritual Letters;" and "A Syſtem and Office for the Solemnity of the Worſhip of the Heart of Jeſus," which the jeſuits employed a conſiderable time in every Catholic country, as a powerful inſtrument in favour of the papal cauſe. Patru, a well known writer, deſcribes Colombiere as one who thoroughly underſtood the niceſt refinements of the French language. Nouv. Dict. Hiſt.

COLOMBINI, COSIMO, an engraver of Florence, who engraved a great part of the portraits of painters inſerted in the magnificent work of the "Muſeum Florentinum." He flouriſhed about 1754. Strutt. Heinecken.

COLOMBONI, DON ANGIOL MARIA, a very celebrated painter of miniature and natural hiſtory, was born at Gubbio in the year 1608, and at a very early period of life became a monk of the order of Mount Oliveto. He made conſiderable progreſs in literature, and in the mathematics, and publiſhed at Bologna, in the year 1669, a book on ſundialling, entitled "Pratica Gnomonica, ovvero Tavole, colle quali ciaſcuno agevolmente puo far da ſe gli Orologi da Sole." But he was not leſs admired for his miniatures, and for his excellent drawings of herbs, flowers, and birds, which he drew with ſuch taſte and correctneſs, and finiſhed with ſuch extraordinary delicacy and ſoftneſs, that he was ſtyled the Giovanni da Udine of his time, and the great Guercino uſed to call him the Raffaelle of his profeſſion. He left two volumes of theſe drawings of birds, in which not only the beautiful colours and the delicacy of the plumage were admirably repreſented, but, what was more extraordinary, each appeared exactly in the attitude moſt uſual to it or moſt characteriſtic. He ſpent great part of his life in Bologna, highly eſteemed, and died in the place of his nativity in the year 1672. Baldinucci.

COLOMBRARO, in *Geography*, a town of Naples, in the province of Baſilicata; 4½ miles S.S.W. of Turſi.

COLOMIES, PAUL, in *Biography*, was born at Rochelle; he embraced the Proteſtant religion, and followed his friend Iſaac Voſſius into England, where he attached himſelf to the cauſe of epiſcopacy, and even attacked the party among whom he had been educated, in a work entitled "Theologorum Preſbyterianorum Icon," which raiſed him many enemies. He was, however, rewarded by being made librarian at Lambeth, and reader at the epiſcopal French church in London. Here he died in January 1692, leaving the reputation of great ſkill in bibliography. He was author of "Gallia Orientalis," in 4to. which was an account of Frenchmen eminent for oriental learning; of a ſimilar work reſpecting Italy and Spain, with many others of conſiderable note at the time in which he flouriſhed. Bayle.

COLOMNA, FABIUS. See COLUMNA.

COLON, in *Anatomy*, from κοιλος, *hollow*; is a name applied to the greater part of the large inteſtine. See INTESTINE.

COLON, in *Grammar*, a point, or character, formed thus (:) ſerving to mark a pauſe, and to divide the members of a period. See POINTING. See alſo PERIOD, COMMA, and SEMICOLON.

Grammarians generally aſſign the uſe of a colon to be to mark the middle of a period; or to conclude a ſenſe leſs perfect than the dot, or period: but a ſenſe leſs perfect than the period, is an expreſſion extremely vague and indeterminate.

Others ſay, a colon is to be uſed when the ſenſe is perfect, but the ſentence not concluded: but neither is this ſufficiently clear and expreſs. Add to this, that in practice, our beſt writers confound the colon with the ſemicolon.

F. Buffier attempts to fix the uſe of the colon; but he does not much diſtinguiſh it from the ſemicolon: he preſcribes the uſe of either, indifferently, and calls them by a common name, *intermediate pointings;* as being mediums between the comma, and full point, or period. Their uſe, according to this author, is to diſtinguiſh the ſupernumerary members of a period. By ſupernumerary members are meant ſuch as the precedent ones do not raiſe any expectation of; *i. e.* ſuch parts as have indeed a dependence on what goes before, even though what goes before has a complete ſenſe, independent hereon: v. gr. "the Auguſtan age was ſo eminent for good poets, that they have ſerved as models to all others: yet did it not yield any good tragic poets;" where the ſupernumerary member, and the uſe of the colon, are obvious. The moſt obvious and ſenſible uſe of the colon, he adds, is, when the ſupernumerary member is diſtinguiſhed by ſome conjunction; as, "notwithſtanding, however, but, except that, unleſs, inaſmuch as, yet, ſince, the rather as, provided that," &c. Some, indeed, uſe the colon in the middle of long periods, without any regard to ſupernumerary members: which cuſtom was probably introduced to mark, that the breath is here to be taken almoſt as much as in a common period, in the place where the ſupernumerary period commences. But this, at beſt, is arbitrary; and the intermediate pointings may always be omitted in a period, if there be no ſupernumerary member, *i. e.* if there be no ſubſequent member, but what is expected from the precedent. As to the occaſions where the colon is to be uſed, rather than the ſemicolon, there is nothing preciſe to be ſaid of it; except that the colon ſhews the ſupernumerary member more detached, and ſets it at a greater diſtance from the reſt; and therefore marks a longer pauſe than the ſemicolon.

Accordingly, it ſeems preferable to uſe the ſemicolon before conjunctions adverſative, reſtrictive, conditional, &c. as, "nevertheleſs, but, excepting that, however, otherwiſe, provided that." Again, where the ſupernumerary phraſes not only ſuppoſe the precedent, but depend on them for their regimen, and are, as it were, new parts thereof; there the ſemicolon ſeems preferable to the colon: v. gr. "You are regardleſs of the goodneſs of God, who firſt choſe you; a God who is only jealous of your heart for your own happineſs; a God who could be equally glorious in deſtroying you by his juſtice, as in ſaving you by his mercy." Or thus: "The diſcourſe conſiſted of two parts; in the firſt was ſhewn the neceſſity of fighting; in the ſecond, the advantages that would redound from it." But this difference, it muſt be owned, has a dependence on ſomething that influences all the points, and ſways the whole doctrine of punctuation; *viz.* the length, or ſhortneſs, of the members and periods: for, when the phraſes are long, we point higher than when ſhort.

A later author, in an ingenious diſcourſe, "De Ratione Interpungendi," marks the office of the colon, and its difference from the ſemicolon, &c. more preciſely; a colon, on his principles, ſerves to diſtinguiſh thoſe conjunct members of a ſentence, which are capable of being divided into other members, whereof one at leaſt is conjunct. Thus, in the ſentence, "as we cannot diſcern the ſhadow moving along the dial-plate, ſo the advances we make in knowledge are only perceived by the diſtance gone over;" the two members being both ſimple, are only ſeparated by a comma: in this, "as we perceive the ſhadow to have moved, but did not perceive it moving; ſo our advances in underſtanding, in that they conſiſt of ſuch minute ſteps, as are only perceivable by the diſtance;" the ſentence being divided into two equal parts, and thoſe conjunct ones, ſince they include others, we ſeparate the former by a ſemicolon, and the latter by commas: but in this, "as we perceive the ſhadow to have moved along the dial, but did not perceive it moving; and it appears the graſs has grown, though nobody ever ſaw it grow: ſo the advances we make in knowledge, as they conſiſt of ſuch minute ſteps, are only perceivable by the diſtance." The advancement in knowledge is compared to the motion of a ſhadow, and the growth of graſs; which compariſon divides the ſentence into two principal parts: but ſince what is ſaid of the movement of the ſhadow, and likewiſe of the growth of graſs, contains two ſimple members, they are to be ſeparated by a ſemicolon; conſequently a higher pointing is required to ſeparate them from the other part of the ſentence, which they are oppoſed to; and this is a colon.

Biſhop Lowth obſerves, that a colon diſtinguiſhes a member of a ſentence, whether ſimple or compounded, which of itſelf would make a complete ſentence, and ſo requires a greater pauſe than a ſemicolon, yet is followed by an additional part, making a more full and perfect ſenſe. He adds, that a colon may be alſo uſed, when a ſemicolon has preceded, and a greater pauſe is ſtill neceſſary, though the ſentence be incomplete; and that it is commonly uſed, when an example, or a ſpeech, is introduced. Introd. to Eng. Gram. ed. 1772. p. 207.

COLONA, in *Botany*, Boſc. Nouv. Dict. Hiſt. Nat. Cavan. tab. 370. Claſs and order, *polyandria monogynia.*

Gen. Ch. *Cal.* five-leaved; leaves linear, coloured on the inſide, caducous. *Cor.* Petals five, with a nectareous ſcale at the baſe. *Stam.* Filaments numerous, inſerted into the top of a pentagonal column. *Piſt.* Germ placed at the top of the column, in the centre of the ſtamens, tetragonous-globular; ſtyle longer than the ſtamens; ſtigma ſimple. *Peric.* Drupe globular, with four wings, opening into four parts. *Seeds* oval, two in each diviſion of the drupe. Nearly allied to Grewia, and differing chiefly in the ſtructure of the pericarp.

Sp. C. *dentata.* A tree. *Leaves* alternate, almoſt ſeſſile, oval, toothed, very large. *Flowers* reddiſh, in axillary, ſolitary racemes, which ſometimes form a panicle. A native of the Philippine iſlands.

COLONÆ, in *Ancient Geography*, a town of Aſia Minor, in the Troade, placed by Strabo at the diſtance of 140 ſtadia from Ilium, in the territory of Lampſacus; it was a colony of Mileſians.—Alſo, a town of the ſame name, placed by Strabo near Chryſa; by d'Anville, S. of Troas.—Alſo, a town, mentioned by Anaximenes, cited by Strabo, and placed in Erythræa.—Alſo, a town of Greece, in Meſſenia, according to Ptolemy; now *Griſſo.*—Alſo, a town of Greece, in the Phocide.—Alſo, the name of a rock, on the bank of the Thracian Boſphorus, over-againſt the Cyanæan iſlands, at the entrance of the Euxine ſea.—Alſo, a town of Greece, in Theſſaly.—Alſo, a promontory near the river Lycus.

COLONEL, the officer who has the chief command of a regiment of horſe, foot, dragoons, or artillery. The lieutenant-colonel commands it in chief in the abſence of the colonel, to whom he is ſubordinate, as the other officers are in like manner to him, when he is preſent.

Colonel *of a regiment of horſe*, is the firſt officer in it, and commands it when preſent. His duty conſiſts chiefly in keeping the regiment complete; in having it compoſed of men and horſes that are fit for ſervice; in taking care to have them well exerciſed and inſtructed in the different evolutions, ſo that they may be able, on all occaſions, to form themſelves ſuitably to the ground they occupy or act on, or to the manner in which they may wiſh either to make or receive an attack. In France, Spain, and ſome other ſouthern nations of Europe, colonels of horſe have been uſually called *maîtres de camp*. But in Germany, and moſt northern nations, they are called *ritmeſters*.

Colonel *of dragoons*. His principal functions are the ſame as thoſe of a colonel of horſe. But he ought to be alſo in ſome meaſure acquainted with the duties of a colonel of infantry, as his men are liable to act either mounted or diſmounted.

Colonel *of foot, or infantry*. His functions are more extenſive and diverſified than thoſe of a colonel of horſe, as the infantry are employed for a greater variety of purpoſes, and on a greater diverſity of ſervices. Colonels of infantry ſhould be well acquainted with fortification, and with field-engineering (which, however, they ſeldom or ever are); ſince ſuch a thorough and comprehenſive knowledge of their principles, as enables an officer to apply them expeditiouſly and judiciouſly, is the beſt and ſafeſt guide to the proper formation and arrangement of troops in various ſituations, and to the advantageous occupation of ground and poſitions. A colonel of infantry ſhould be particularly careful to maintain union and harmony among his officers, and contentment among his men; to acquire the eſteem and confidence of both, and to make himſelf be reſpected by them; to which nothing contributes more than a ſteady, uniform, and impartial enforcement of ſubordination and diſcipline. He ſhould likewiſe be peculiarly attentive to the health and comfort of his men.

Colonel *of Artillery*; the commander of a battalion of artillery. His duties, when properly underſtood and attended to, are various and laborious, both in war and peace, and require, in order to be well performed, not only abilities, but alſo application, knowledge, and experience. He ought to be an able mathematician and mechanic, and ſhould be acquainted with all the duties of an engineer, that are connected with the uſe and application of artillery in different ſituations, and to different purpoſes; the conſtruction of batteries, platforms, field-works, the occupying of poſitions with artillery, to the beſt advantage, both as to direct and flanking fires, &c. Whatever ſituation he may be placed in, or on whatever ſervice he is going, he ſhould underſtand thoroughly what nature and ſpecies of ordnance is beſt adapted to it. He ſhould be acquainted with all the beſt and moſt uſeful experiments, that have been made with artillery in the different nations of Europe; he ſhould know the greateſt diſtance at which walls can be battered in breech effectually; the different charges of powder, beſt adapted for different ſervices, and different diſtances. And he ſhould not only be well acquainted with the wide differences between the ranges of cannon-ſhot and ſhells in the air, and thoſe which the parabolic theory gives for them *in vacuo*, but alſo be able to approximate, nearly to the truth, the diſtances to which projectiles will go in the air, thrown with given charges of powder, and given degrees of elevation. In ſhort, he ought to know a variety of things, which few officers of artillery actually do know.

Colonel *of Engineers*. See the article Engineer.

Colonel, *Lieutenant*, is, as has been already obſerved the ſecond officer belonging to a regiment, and commands it in the abſence of the colonel.

Colonel *General of the French Infantry*, or Colonel *General d'Infanterie Françoiſe*: an appointment of great truſt and authority, which took its birth, or originated, under Francis I. in 1544. It became an immediate gift of the crown, under Henry III. in 1584. It was at laſt ſuppreſſed, becauſe it gave too many prerogatives, and too much power to the perſon who was inveſted with it. Under Louis XV. however, it was re-eſtabliſhed in 1711, in favour of Louis, the firſt duke of Chartres. This officer had originally the right of nomination to every commiſſion and place of truſt in the infantry. He could order courts martial, and enforce the ſentences awarded by them, without any ſuſpenſion of his power in that reſpect. by an appeal to a ſuperior tribunal; and he had a company in every regiment of infantry, which was called the colonel general's company.

Colonel *Général d'Infanterie de Suiſſes et Griſons*. This appointment was not held of the crown; but it was almoſt always given to a prince. It took its riſe in right of office under Charles IX. in favour of the ſon of the conſtable of Montmorency, killed at the battle of St. Denis. All the Swiſs and Griſon troops were ſubordinate to the colonel general, the company *des cent Suiſſe de la garde* excepted. He appointed colonels and captains. The ſovereigns at laſt aſſumed, or reſumed, this right of nomination. But he ſtill retained the right of naming and preſenting to the king the officers of the nation, to be included in the promotion of general officers, and enjoyed ſeveral other prerogatives.

Colonel *Général de la Cavalerie légére et étrangére*. This charge, or employment, was created in right of office under Charles IX. It was, however, known before his time, in 1449, under the title of "capitaine general de la cavalerie Albanoiſe." Under Louis XIII. there were two ſuch colonels general, one of the French cavalry, and the other of the German cavalry. Though theſe general officers enjoyed great honours and prerogatives, the generals of the Roman cavalry, under the emperors, were perſons of ſtill greater importance. For they had the ſame authority over the troops and militia, that the kings and dictators had. The emperors treated them in their regulations and conſtitutions, as ſeignors of the higheſt rank, eminence, magnificence, and celebrity. They enjoyed an authority almoſt abſolute, over all military people.

Colonel *General des Dragons*, colonel general of dragoons. This appointment was created in 1688, by Louis XIV. It was, like the preceding ones, favoured with an attribution of great honours and particular prerogatives.

Colonel *de Troupes Légères*, colonel of light troops. This officer ought to be well inſtructed, both by ſtudy and experience, in the art of petty warfare, and the management of detachments. For, as he is almoſt always reſponſible for the corps confided to his charge, and forced to take advanced poſitions in an enemy's country, he is of conſequence the more expoſed to be ſurpriſed, taken, or at leaſt beaten.

COLONELLE, Compagnie, the firſt company in a French regiment.

COLONI, Adam, called the Old, in *Biography*, a painter who was born at Rotterdam, in 1634, but afterwards reſided and died in London, in 1685. The ſubjects of his pictures were generally wakes, country fairs, rural ſubjects, and cattle; beſides which, he made ſeveral copies from the pictures of the Baſſans, with ſucceſs. He had a ſon called Adrian Coloni the young, who received inſtructions from his brother-in-law, Van Dieſt, in addition to the leſſons beſtowed on him by his father. He frequently painted the figures in the landſcapes of Van Dieſt, as well as in thoſe of other maſters; and ſometimes imitated the touch of Salvator Roſa. At other times he produced pictures of hiſtory, but more generally thoſe of cattle, converſations, or landſcapes. Adrian died in the year 1701, aged 33. Pilkington.

Coloni, *Cape*, in *Geography*, lies on the W. coaſt of Aſiatic Turkey, N. of the gulf of Smyrna. N. lat. 39°. E. long. 26° 36′.

COLONIA, in *Ancient Geography*, an epiſcopal town of Aſia, under the metropolis of Sebaſte; ſituate in the firſt Armenia, and called alſo *Taxara*.—Alſo, an epiſcopal town of Aſia, in Cappadocia.—Alſo, a town of Italy, in Etruria.—Alſo, a town of the Iſle of Albion, in the route from Londinium to Lugwallium ad Vallum, between Cæſaromagus and Villa Fauſtini, according to the Itinerary of Antonine. Although our antiquarians are divided about the ſituation of Colonia, it ſeems, upon the whole, to be moſt probable that it was at Colcheſter, on the river Colne, from whence it derived its name.—Alſo, a town of the Damnii, according to Ptolemy, which ſome, as Camden and Baxter ſuppoſe, to have been Coldingham in the Mers, but which was more probably ſituated at or near Lanark, in Clydeſdale. See Coldingham.

Colonia, in *Geography*, a town of Iſtria; five miles S.S.E. of Rovigno.

Colonia *Agrippina Ubiorum*, in *Ancient Geography*, a town ſeated on the banks of the Rhine; now Cologne. It was built by the Ubii, when they left Germany to eſtabliſh themſelves in Gaul. Agrippina, the mother of Nero, fixed a colony of veterans in this place, and gave it her name in honour of the place of her birth.

Colonia *Equeſtris*, a town of Gallia Belgica, aſſigned by Pliny to the Helvetians; but by Ptolemy to the Sequani. The Itinerary of Antonine marks it under the name of "Equeſtris," between Bautas and Lacu Lauſanio. It was alſo called "Noiodunus," or "Nividunum;" but when it became a colony, the Romans called it "Colonia Equeſtris." It is now *Nion*.

Colonia *Flavia*, the town called Cæsarea of *Paleſtine*.

Colonia *Julia*, a town and Roman colony of Germany; now *Bonn*.

Colonia *Julia Celſa*, a town of Spain, which was a Roman colony; now a village called *Xelſa*.

Colonia *Julia Hiſpella*, a town and Roman colony of Italy, in Umbria; now *Spello*.

Colonia *Marcia*, a town of Spain, which had the title of Roman colony; now *Marchana*.

Colonia *Senenſis*, a town of Italy, in Etruria, which was a Roman colony; now *Sienne*.

Colonia *Septimanorum Juniorum*, a town of Gaul, with the title of colony; now *Beziers*.

Colonia *Trajana*, now *Koln*, or *Keln*, was ſituated at a ſmall diſtance from the Rhine, and about a mile from Cleves.

Colonia *Ulpia*, is now *Cleves*, which ſee.

COLONIDES, called *Colone*, by Ptolemy, a town of Meſſenia, ſeated on an eminence on the coaſt which bore northwards to the weſt of the gulf of Meſſenia. Its inhabitants are ſaid to have been conducted under the direction of an oracle, by a perſon named Colonus, from Attica to this country. In proceſs of time they aſſumed the manners and language of the Dorians. The mountain Temathea, called by Pauſanias Temathia, commenced towards Colonis, and extended itſelf towards the north-weſt, as far as mount Egaleus.

COLONIS, an iſland of Greece in the Argolic gulf, according to Pliny.

COLONNA, Giov. Paolo, Maeſtro di Capella di San Petronio di Bologna, in *Biography*, was the ſon of Antonio Colonna, alias del Corno, a celebrated organ builder of Breſcia. He compoſed but few operas; indeed, we know of but one, Amilcar in Cipro, for the theatre of Bologna, 1692; but he publiſhed about the latter end of the laſt century many excellent works for the church, of which P. Martin has given a liſt, to the amount of twelve, in the ſecond volume of his Hiſtory of Muſic.

It was the opinion of the late Dr. Boyce, that Colonna was Handel's model for choruſes accompanied with many inſtrumental parts, different from the vocal. But it muſt, however, be owned, that Handel has greatly ſurpaſſed his model in energy, fire, and vigour of genius. The pſalms of Colonna in eight real vocal parts, publiſhed at Bologna in 1694, have been very juſtly admired for their maſterly compoſition. Paolucci has inſerted the hymn, "Pange lingua," ſet in plain counterpoint of four parts by him, in a manner ſufficiently ſimple and ſyllabic for the moſt zealous reformers of church muſic. His "Sacre lamentationi della ſettimana ſanta, a voce ſola," publiſhed 1689, contain many pleaſing and elegant fragments of pathetic recitative, which we ſhould have admired much more if we had not previouſly been acquainted with the works of Cariſſimi, who had anticipated not only all the thoughts of Colonna in this ſpecies of muſic, but almoſt all thoſe of every compoſer of the preſent century. The airs of theſe lamentationi are too ſhort to make much impreſſion on the hearer.

Colonna had a controverſy with Corelli in 1685, concerning the conſecution of fifths in the firſt movements of the third ſonata of his Opera 2da. Every lover of muſic will be ſorry that the charge againſt Corelli ſhould be well-founded; but it muſt be owned that the baſe is indefenſible in the paſſage which has been condemned by Colonna, and was not likely to have paſſed uncenſured, even in an age much more licentious than that of Corelli.

Antimo Liberati, with whom Colonna was in correſpondence at the time of this controverſy, ſeems to defend Corelli's violation of the known rule againſt the conſecution of fifths, in a letter written 1685, "Sopra un ſeguito di quinte," in which he reaſons thus: "If a quaver reſt, or even a ſemiquaver, were not ſufficient to ſatiſfy the rule againſt fifths and eighths, a compoſer writing in many parts would have very narrow limits for the expanſion of his genius and fancy, or for varying the harmony." But with due reſpect for the authority of Antimo Liberati, and with peace to the aſhes of the gentle Corelli, the paſſage is unwarrantable, and ſeems the more inexcuſable, as ſeveral better baſes were eaſy to find, without altering his deſign, or deſtroying the effect of his trebles. It appears that the excellent theoriſt Berardi had a reverence for the profeſſional erudition of Colonna, by his dedicating to him the ſeventh chapter of his "Miſcellenea Muſicale."

Colonna, Michale Angelo. See Angelo.

Colonna, Marc-Antonio, bore arms from an early age in the ſervice of the Spaniards, and roſe to great military reputation. He was appointed by pope Pius V. general of his galleys, and ſerved in the famous battle of Lepanto, gained againſt the Turks in 1571. On his return, the pope honoured him with a triumphal entry after the manner of the ancient Roman conquerors. He poſſeſſed ſeveral high civil poſts, as conſtable of Naples, and viceroy of Sicily, and died in Spain in 1584. Moreri.

Colonna, Ascanio, was ſon of Marc Antonio, and educated under his father's roof by the celebrated Muretus.

He accompanied his father into Spain, and ſtudied at the univerſities of Alcala and Salamanca. Philip II. gave him an abbacy, and he was made cardinal by Sextus V. At the death of the king his patron, he delivered a funeral oration, which he printed. He was himſelf a promoter of literature, and collected a magnificent library. Owing to his great ſkill in canonical law, and the ſupport which he gave to the claims of the Catholic king, he was made viceroy of Catalonia. He afterwards wrote a canonical defence of the pope's conduct in his diſpute with the republic of Venice. This and ſome other letters and harangues he publiſhed, and died at Rome in 1608. Moreri.

Colonna, Fabius. See Columna.

Colonna, Francisco, was born about the middle of the fifteenth century, probably at Venice, and entered young into the order of Dominicans. The work by which he is chiefly known is "Hypnerotomachia di Poliphilo," which ſignifies *the combat of Love in a dream*, and *the Lover of Polia*. It conſiſts of fable, hiſtory, allegory, architecture, mathematics, &c. and is written in a language compounded of words taken from ſix or ſeven different languages. It was printed by Aldus in 1499, and a French tranſlation was publiſhed in 1546, and has been ſeveral times re-printed. The original and tranſlation have been in great requeſt among collectors of books, as well on account of their ſcarcity, as for the ſake of the beauty of the numerous wooden cuts with which the work is decorated. Colonna died at an advanced age, at Venice, in the year 1527.

Colonna, Prospero, a diſtinguiſhed military commander, was younger ſon of Anthony prince of Salerno, and born about the year 1452. He engaged in the ſervice of Ferdinand king of Naples, and after his death, in that of Charles VIII. king of France. When that prince undertook the conqueſt of Naples, Colonna, with his couſin Fabritio, rendered him ſome ſignal ſervices, but upon a change of politics, they returned to their former allegiance. Proſpero aſſiſted in the recovery of the kingdom of Naples; he was at the battles of Barletta and Garigliano, at which the French were worſted; and he ſignalized his valour and conduct at a variety of ſieges and other military actions. In the year 1515, while attempting to defend the paſſage of the Alps againſt the French, he was made priſoner, and carried to France, but being liberated, he reſumed his profeſſion in order to revenge the diſgrace that attached to him while a captive. He died in 1523, aged ſeventy-one, leaving behind him a very high character as a general; he was rather prudent and cautious than formed for remarkable enterpriſes. Though ſlow and inactive, he was, by conſtant vigilance, generally ſecured from ſurpriſe. He was the friend and patron of learned men. Moreri. Robertſon's Hiſt. ch. v. vol. ii.

Colonna, Pompeo, was brought up by his uncle Proſpero, and deſtined by him for literary purſuits. The young man inclined to the profeſſion of arms, and diſtinguiſhed himſelf as a military man till he was compelled to aſſume the eccleſiaſtical character. He was made biſhop of Rietti, and obtained many lucrative benefices. He was, however, little attentive to the duties of his ſacred office, and ſo regardleſs of the decorum that ought to be attached to it, that he accepted a challenge, and tore his caſſock to pieces that he might not be prevented from fighting. On a falſe report of the death of pope Julius II. in 1512, Pompeo joined in raiſing the cry of liberty, and took poſſeſſion of the capitol. For this he was deprived of his benefices, but by the intereſt of his uncle, matters were again accommodated, and in 1517, he was elevated to the rank of cardinal. Still, however, inclined to turbulent meaſures, his conduct gave his enemies the opportunity of charging him with the intention of putting the pope to death, in order that he might ſucceed to that high dignity; he was accordingly deprived of his offices, in which he was reinſtated on account of ſome important ſervices which he rendered to the reigning pontiff. He was afterwards viceroy of Naples, where he died in 1532. He was eſteemed a patron of literature, and wrote a poem "De laudibus mulierum," chiefly in praiſe of Vittoria Colonna. Moreri. Robertſon's Hiſt. ch. v. vol. ii.

Colonna, Vittoria, a learned lady and poeteſs, was born at Marino in 1490. At the age of ſeventeen, ſhe married Ferdinand Francis D'Avalos, marquis Peſcara, who, by her influence, was diſſuaded from accepting the kingdom of Naples, which was offered him after the victory of Pavia, in order to detach him from the ſervice of the emperor Charles V. After his death, which happened in 1525, ſhe lived in retirement, devoting herſelf to poetry; ſhe kept up, with much credit to herſelf, a friendly and learned correſpondence with ſome of the moſt celebrated literary characters of the age. In 1541, ſhe retired to the monaſtery at Orvieto, and from thence ſhe went to St. Catharine in Viterbo, but in 1547, ſhe returned to Rome, where ſhe died. Her poems have paſſed through many editions, and have been printed with the commentaries of learned men. Moreri.

Colonna, in *Geography*, a town of European Turkey in Dalmatia; 24 miles N. of Spalatro.—Alſo, a town of Italy, in the Campagna di Roma; 12 miles from Rome.—Alſo, a cape of Naples, on the E. coaſt of Calabria Ultra. N. lat. 39° 6'. E. long. 17° 26.'

COLONNADE, the name given to any range of inſulated columns. See Portico.

COLONNE, in *Geography*, a town of France, in the department of the Jura, and chief place of a canton in the diſtrict of Poligny; 2 leagues W.N.W. of Poligny.

COLONNI, a cape on the coaſt of the Morea, in the Mediterranean. N. lat. 37° 32'. E. long. 24° 11'.

COLONOSSIS, in *Ancient Geography*, a place of Aſia, in Lycaonia.

COLONSAY, in *Geography*, one of the iſlands of Scotland, called the Hebrides. It belongs to Argyllſhire, and as it is ſeparated from Oranſay, merely by a narrow channel, which is dry at low water, Colonſay and Oranſay may be conſidered but one iſland. Although the eminences of the former cannot correctly be termed mountains, they are high, rugged, and covered with heath. The arable land, which conſiſts of about 3000 acres, produces early and tolerable crops, as the ſoil is light and mixed with ſand along the ſhores; part of this land has lately been converted into paſture, and numbers of black cattle are fed on the two iſles. A monaſtery of Ciſtertian monks formerly flouriſhed in Colonſay, and the remains of the walls of the abbey gave place ſome years paſt to a farm houſe; a priory attached, ſtood in Oranſay, where the ruins ſtill remain, and are conſidered ſuperior to any other religious building in the Hebrides, with the ſingle exception of Icolmkill; there are beſides fragments of ſeveral chapels in Colonſay. The inhabitants make large quantities of kelp from the ſea-weed found on the coaſt; and the banks which ſurround the iſlands produce plenty of fine coral. The population is eſtimated at about 720, and the duke of Argyll is the principal proprietor.

Colonsay, *Little*, an iſland, and one of the Hebrides, ſituated between Gometra and Staffa. There are ſeveral ſpecimens of baſaltic pillars in the Leſſer Colonſay, but it has no other inhabitants than one family who attend a few ſheep.

COLONUM, a place of Greece, in Attica. Here was
a foreſt

a foreſt conſecrated to the Eumenides. Sophocles, according to Suidas, was born in this place.

COLONUS, an huſbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year, to plow ſome part of the lord's land; and from hence comes the word *clown*, who is called by the Dutch *boor*.

COLONY, Colonia, is properly a number of perſons of all ſexes and conditions, tranſported into a remote province, with a view of remaining there, and for the purpoſe of cultivating and inhabiting it; but among commercial nations, the term is uſed in a larger but leſs proper ſenſe, and applied to the temporary reſidence of merchants and agents in another country. The word colony originally ſignified no more than a *farm*, i. e. the habitation of a peaſant, *colonus*, with the quantity of land ſufficient for the ſupport of his family; "quantum colonus unus arare poterat." It is derived from the Latin word *colo*, I till or cultivate; hence *colonus*, a huſbandman, and *colonia*, a body of farmers, ſent to cultivate the ground in a diſtant country, and, by metonymy, the place itſelf. From the Latin the word has paſſed, with ſcarcely any alteration, into the modern languages of the weſt of Europe.

We may diſtinguiſh, generally, four kinds of colonies; *viz.* 1. Thoſe that ſerve to eaſe or diſcharge the inhabitants of a country, where the people are become too numerous, ſo that they cannot any longer conveniently ſubſiſt together. 2. Thoſe eſtabliſhed by victorious princes and people, in the middle of vanquiſhed nations, to keep them in awe and obedience. 3. Thoſe that are formed by emigrants, driven from their native country by oppreſſion and perſecution to ſeek a foreign ſettlement, and to ſubſiſt firſt by agriculture, and afterwards by commerce. 4. Thoſe that may be called "colonies of commerce;" becauſe trade is the ſole occaſion and object of them.

To the *firſt* claſs we may refer the colonization which took place in the earlier ages of the world, and which ſerved to diſſeminate the human race, firſt through the various regions of the eaſt, and afterwards through other more remote parts of the globe. At this early period colonization was of courſe more frequent than it is at preſent. The increaſe of a tribe beyond the limits of a comfortable ſubſiſtence upon the lands which were occupied, would be a ſufficient motive for inducing the younger members of the ſociety to remove from the proſpect or actual preſſure of want, to ſome unoccupied territory. Some authors, however, are of opinion that ſoon after the deluge, when the deſcendants of Noah became numerous, a diviſion of the ancient continent and its adjacent iſlands was made, probably by lot, among the heads of the ſeveral families. This opinion ſeems to be in ſome meaſure ſupported by the authority of Moſes, who ſays, (Gen. x.) on mentioning the children of Eber, that the name of one of them was "Peleg" (diviſion), for in his days was the earth divided." (See Dispersion.) However this be, the gradual extenſion of the habitations of mankind muſt have correſponded with their increaſe; and it ſeems to have been unreſtrained by claims made upon the uncultivated ſpots. But this unlimited right of diſperſion has long ſince ceaſed in moſt parts of the world; and hence it has become neceſſary for coloniſts, who ſeek new ſcenes for their labours, either to unite with the natives as friends, or to ſubdue them by conqueſt, if the colony is founded upon hoſtile principles. At a ſubſequent period, the different ſtates of ancient Greece, ſuch were Athens, Sparta, Corinth, and Argos, poſſeſſed territories of very limited extent; and the increaſe of population gave riſe to various emigrations from all thoſe ſtates. The colonies of the Dorians reſorted chiefly to Italy and Sicily, which, in the times preceding the foundation of Rome, were inhabited by barbarous and uncivilized nations; thoſe of the Ionians and Eolians, the two other great tribes of the Greeks, to Aſia Minor and the iſlands of the Ægean ſea, the inhabitants of which ſeem at that time to have been pretty much in the ſame ſtate as thoſe of Sicily and Italy. The emigrations now mentioned, and ſome others of a ſimilar nature, were undertaken by private individuals, with no authority from the government; and as they were generally directed towards diſtant and tranſmarine ſettlements, they retained but a ſlight connection with their original countries. The parent ſtate, indeed, conſidered the colony as a child, at all times entitled to great favour and aſſiſtance, and owing in return much gratitude and reſpect; but, moreover, conſidered it as an emancipated child over whom no direct authority or juriſdiction was claimed. The colony ſettled its own form of government, enacted its own laws, elected its own magiſtrates, and made peace or war with its neighbours as an independent ſtate, which had no occaſion to wait for the approbation or conſent of the parent city. The coloniſts, indeed, remembered the land of their fathers with filial affection and reſpect; they honoured its gods, by offerings of firſt-fruits to their temples; they retained a predilection for its cuſtoms and laws, as well as its religion and language; they yielded to its citizens the place of diſtinction at public games, and to its prieſts the holy honour of firſt inſpecting the entrails of ſacrifices. In war they generally followed the fortunes of the metropolis, as allies upon equal terms; but as they were perfectly independent, received no protection from her, and often equalled her in reſources, they always refuſed to come forward as auxiliaries, when unfair terms were propoſed. Thus, the Sicilian colonies refuſed to admit an Athenian army into their territories, for the purpoſe of reſting, on an expedition; and, in the Perſian war, the republic of Syracuſe, when intreated by the Lacedæmonians to aid the common cauſe, refuſed to ſend any aſſiſtance, unleſs their chief magiſtrate, Gelon, were allowed to command the united forces. Sometimes the parent country, conſcious of her ſuperiority and ſtrength, attempted to exact from the colonies, as matter of right, the uſual marks of filial attachment. Thus, Corinth was deſpiſed by her colony at Corcyra, for her inferiority of wealth and trade; and ſhe endeavoured to obtain by force, the uſual tokens of remembrance. The coloniſts appealed to Athens, who took their part, and retained them as uſeful allies, eſpecially during the Peloponneſian war. Potidæa, another Corinthian ſettlement, took the part of Athens, until her impolitic tyranny urged it to throw off the yoke, and appeal to Sparta and Corinth. After a long and ſevere ſtruggle, the Athenians were ſucceſsful; ſent new colonies to occupy the confiſcated and vacant lands; continued their oppreſſive government; and retained their dominion over Potidæa, until the invaſion of Philip. When the progreſs of Cyrus expoſed the Aſiatic colonies of Greece to extreme danger, they in vain applied to Sparta for aſſiſtance; and, being ſoon conquered by the Perſian monarch, they remained in ſubjection, until the victories of Plateæ and Mycale reſtored them to freedom; but deſpairing of long maintaining their independence, they formed a ſtrict alliance with Athens, who availed herſelf of the opportunity of a general alarm, to propoſe an univerſal contribution from all her colonies and allies, for the great purpoſe of reſiſting the Perſian power. We might cite many other inſtances to exemplify the independence of the Grecian colonies on the ſtates from which they originated. Nevertheleſs, the benefits in point of civilization reſulting to barbarous countries from colonies of private adventurers, migrating from countries more advanced in the knowledge of thoſe arts which meliorate the condition of human life, have entailed honour on thoſe who imparted them, and claimed returns of reſpect and gratitude from thoſe on whom they were beſtowed. From this mode of colonization, reciprocal advantages have been derived. The natives already in poſſeſſion of the country, to which colonies have migrated, are benefited by the introduction of new arts; while, at the ſame time, the adventurers receive the reward of their knowledge, valour, and conduct, by the ſuperior degree of influence which they acquire beyond what they would have poſſeſſed if they had remained in their own country. Thus individual adventurers, who have fitted out expeditions at their own charge, and conducted colonies to a permanent ſettlement by their own ſkill and valour, have, in ſome memorable inſtances, attained even to ſupreme authority. This ſeems to have been the caſe with regard to the colonies anciently eſtabliſhed by Ægialeus in Sicyon, by Inachus in Argos, by Cecrops in Attica, by Janus in Italy, and by Cadmus at Thebes in Greece. From the veneration in which the memory of theſe adventurers, who were moſtly of Egyptian origin, were held, it is evident that they had imported into the countries where they ſettled great and important improvements. The great literary renown which Athens acquired in progreſs of time has rendered us better acquainted with its early hiſtory; ſo that we can form ſome idea of its primitive laws. The regulation of the connexion between the ſexes is recorded as being due to Cecrops; from whence ſome etymologiſts, as Euſtathius, deduce the origin of the appellation διφυὴς, by which he was diſtinguiſhed. The collection of the inhabitants into towns and villages, is ſaid to have been an improvement of his immediate ſucceſſors, who, it is probable, alſo introduced the regulation of local juriſdictions, and the diviſion of the land in property among the then exiſting heads of families, to be inherited by their deſcendants. This ſeems to be, in fact, the main foundation of perfect civilization, by introducing this inequality of condition, as ſome of the families increaſed or proſpered more than others, which, notwithſtanding the reveries of ſome ſpeculative politicians, is abſolutely neceſſary to civilized life. This mode of colonization is ſeldom attempted in more modern times, becauſe the maritime nations of Europe have laid claim to all heathen lands which their ſubjects diſcovered, and have prevented even their own ſubjects from endeavouring to ameliorate the condition of theſe countries, by attempting the formation of independent Chriſtian ſtates. The Jeſuits had, indeed, formed a conſiderable eſtabliſhment for the improvement of the natives in South America; but it gave umbrage to the Portugueſe government, and the neglect of military affairs rendered the overthrow an eaſy undertaking. The Moravian brethren have ſimilar ſettlements in the moſt northern parts of America and Europe, where the inhoſpitality of the climate is ſuch, that the country is not worth contending for. The eſtabliſhment of the Macedonian dynaſties in Aſia and Egypt; and, in later times, that of the northern tribes in the ſouthern parts of Europe and of Aſia, are ſignal examples of this mode of colonization. It is notorious, that it was for the eſtabliſhment of colonies, referred to the firſt claſs abovementioned, that, during the declenſion of the Roman republic, thoſe torrents of barbarous nations, iſſuing, for the generality, out of the north, over-ran the Gauls, Italy, and the other ſouthern parts of Europe; and, after ſeveral bloody battles, divided it with the ancient inhabitants, and blended their own habits and manners with thoſe of the nations which they ſubdued, or in which they obtained either temporary or permanent ſettlements.

To the *ſecond* claſs of colonies belong thoſe of a military nature, which ſerved as guards or garriſons, for the maintenance of a conquered country. The Romans recurred to this mode of colonization more frequently than any other nation; and added, to the original motive, that of providing retreats for the aged and worn-out ſoldiers; as alſo for the ſettlement of the poorer claſſes of Roman citizens. Nor were the intereſts of the rich forgotten, in the eſtabliſhment of Roman colonies. The ſpirit of the Roman laws having reſtrained the mercantile claſſes to their proper rank in ſociety, the capital accumulated by their commanders, during the long continued and widely extended ſucceſſes of the Roman republic, was of courſe inveſted in land. The extent of Italy was too ſmall for the capital, thrown, by this means, into agriculture; and the capitaliſts were therefore obliged to ſeek new lands, on which it might be employed. It appears that the eaſtern ſhores of the Mediterranean ſea were, at the time of their falling under the Roman dominion, in the higheſt poſſible ſtate of cultivation. The provinces ſeated on theſe ſhores, were, therefore, the ſcenes of oppreſſion rather than of improvement, and the plunder, accumulated there, was transferred to Gaul, and other weſtern provinces, to be employed in the purchaſe and improvement of land, or in loans to thoſe who reſided there. The high rate of intereſt allowed by the Roman laws, made it alſo far better to employ money in loans than in commercial ſpeculations, which cannot be ſuppoſed, in the reſtricted and degraded ſtate of Roman commerce, to have yielded the ſame profit as the former. Seneca, the philoſopher, is ſaid to have had, at the time of his death, no leſs than 600,000 *l.* ſterling due to him from the coloniſts in Britain; the ſudden calling in of which produced a rebellion. Beſides, Rome, like moſt of the other ancient republics, was originally founded upon an Agrarian law, which divided the public territory in a certain proportion, among the different citizens who compoſed the ſtate. The courſe of human affairs, by marriage, by ſucceſſion, and by alienation, neceſſarily deranged this original diviſion, and frequently threw the lands, which had been allotted for the maintenance of many different families, into the poſſeſſion of a ſingle perſon. To remedy this diſorder, a law was made reſtricting the quantity of land which any citizen could poſſeſs to 500 jugera, or about 350 Engliſh acres. This law, however, was neglected or evaded, and the inequality of fortunes went on continually increaſing. The greater part of the citizens had no land, and without it the manners and cuſtoms of thoſe times rendered it difficult for a freeman to maintain his independency. The people, therefore, became clamorous to get land, and the rich and great, we may readily imagine, were determined not to give them any part of theirs. To ſatisfy the unquiet and clamorous people, it was frequently propoſed to ſend out a new colony. Accordingly, Rome aſſigned them lands, generally in the conquered provinces of Italy, where, being within the dominions of the republic, they could never form any independent ſtate; but were, at beſt, merely a ſort of corporation, which, though it had the power of enacting by-laws for its own government, was at all times ſubject to the correction, juriſdiction, and legiſlative authority of the mother city. The ſending out of a colony of this kind, not only gave ſome ſatisfaction to the people, but often eſtabliſhed a ſort of garriſon, too, in a newly conquered province, of which the obedience might otherwiſe have been doubtful and precarious. Some of theſe colonies were of a civil, and others of a military nature. In their manners and internal policy, the colonies formed a perfect repreſentation of their great parent; and they were ſoon endeared to the natives by the ties of friendſhip and alliance; they effectually diffuſed a reverence for the Roman name, and a deſire, which was ſeldom diſappointed, of ſharing, in due time, its honours and advantages. A Roman colony, whether we conſider the nature of the eſtabliſhment itſelf, or the motives for making it, was altogether different from a Greek one. The words, accordingly, which, in the original languages, denote thoſe different eſtabliſhments, have very different meanings. The Latin word, *colonia*, ſignifies ſimply a plantation. The Greek word *αποικια*, on the contrary, ſignifies a ſeparation of dwelling, a departure from home, or a going out of the houſe. In conformity to this diſtinction of names, we may obſerve, that the colonial ſettlements of the Greeks were planted in diſtant countries, and amongſt barbarous tribes. They were eſtabliſhed, not in Greece, or in the ſtates immediately in the neighbourhood, which had already been well peopled, but in Gaul, Sicily, and the ſouth of Italy; in Cyrene and Egypt; in Illyria and Aſia Minor. The Roman colonies, on the other hand, were at firſt planted in the immediate vicinity of Rome. During the ſecond Punic war, the city was ſurrounded by no fewer than 30 eſtabliſhments of this kind; which ſerved as ſo many garriſons or advanced poſts for her defence. Ancient authors mention no leſs than 164 colonies ſettled in Italy, from the foundation of Rome to the death of Auguſtus; whereas thoſe planted in all the provinces were only 199. From this conſideration it appears, that the Italian colonies were materially different in their conſtitution and uſes from the colonies of the provinces. The emigrations from Rome to the conquered towns and lands of Italy, and afterwards of the foreign provinces, were the operations of war and plunder. Whenever an Agrarian diviſion of conquered territory was proclaimed, the diſcontented citizens preſented themſelves in a body; and if a ſufficient number did not offer to form a legion for retaining the conqueſt, which they called a colony, the deficiency was ſupplied from all the tribes by lot. As this ſyſtem of conquering policy was effected ſlowly, until the whole of Italy had been ſubdued no emigration ever took place to any tranſmarine, or tranſalpine countries. Among the Romans there were two kinds of colonies; thoſe ſent by the ſenate, and thoſe that were military, conſiſting of old ſoldiers, broken and diſabled by the fatigues of war, who were thus provided with lands, as the reward of their ſervices. The colonies ſent by the ſenate were either Roman or Latin, *i. e.* they were compoſed of Roman or Latin citizens. The colonies of Roman citizens had the right of ſuffrages, and could reclaim the rights of citizens whenever they choſe to remove to the capital. The Latin coloniſts loſt their rights for ever, nor had they any right of ſuffrages without an expreſs permiſſion. According to Ulpian (lib. i. D. de Cens.), there were other colonies, which had little more than the name; only enjoying what they called *jus Italicum*, *i. e.* they were free from the tribute and taxes paid by the provinces; ſuch were the colonies of Tyre, Berytus, Heliopolis, Palmyra, &c. Between all the Roman colonies and the metropolis, there ſubſiſted the cloſeſt connexion. The form of colonial government was modelled upon that of Rome. The laws, if not changed at once, were gradually moulded by the ſpirit of the Roman juriſprudence; the officers were almoſt all ſent from the capital; the mandates of the republic were more promptly obeyed in the provinces than in the city itſelf;—in a word, the eſtabliſhments which have been called colonies, and, compared to thoſe of modern times, or of the Greeks, were military ſtations; garriſons, placed in conquered countries; advanced poſts of a great army, of which the commander in chief held his head quarters in Rome, and occaſionally made a progreſs through the different cantonments. From theſe ſettlements taxes were levied, according to a cenſus; and, after paying the expences of their own government, they tranſmitted a revenue to the Roman treaſury. Men were raiſed for the Roman army according to a muſter-roll. When the grandeur of the Roman name extended acroſs the ocean and the Alps, the rights of citizenſhip became valuable, as the title to power, honours, and plunder. The allies, or colonial and provincial ſettlements of Italy, then demanded the communication of this privilege; and the refuſal produced that "Social war," which may be juſtly deemed the end of the regular republican conſtitution. In conſequence of the Julian law, which terminated this war, and of other laws afterwards paſſed, all the ſtates of Italy, whether allies, colonies, or prefectures, obtained the full rights of Roman citizens. Until the year U.C. 640, no colony but one, which never flouriſhed, had been planted beyond the confines of Italy. The military colonies, introduced by Sylla, and much favoured by Auguſtus, were remarkable only for a form of government more entirely military than that of the other ſettlements. All were equally ſubordinate to the central government, and equally obedient to its decrees.

The firſt foreign colony which the Romans planted was in Carthage, A.U.C. 710, when Julius Cæſar formed the plan of reſtoring that deſerted city by means of a colonial eſtabliſhment. The firſt colony planted in Italy was that of Cænnia, A.U.C. 4. The practice of ſending Roman colonies to the provinces, where they did not enjoy all the privileges of the Italian coloniſts, was very common after the experiment of Julius Cæſar. He himſelf tranſplanted 80,000 citizens in this manner. (Sueton. in Jul. Cæſ. c. 42.) After the time of Auguſtus, who planted 28 colonies in Italy (Suet. in Octav. c. 46.), the cuſtom of planting Italian colonies ſeems to have been abandoned. His ſucceſſors did not plant ſo many as 20; and preferred forming thoſe ſettlements beyond ſeas. Livy does not even mention a tranſmarine or tranſalpine colony; although he conſtantly relates the foundation of thoſe in Italy. Dacia and Britain, the moſt difficult and inſecure of the Roman conqueſts, had only, the former four, and the latter five, Roman colonies. Twenty-five colonies were ſettled in Spain; and Africa, the moſt peaceable of all the Roman poſſeſſions long before the downfal of the commonwealth, received, after the uſurpation of Julius Cæſar, no leſs than 57 colonies, excluſive of Egypt. From theſe circumſtances we may be led to conclude, that the Italian eſtabliſhments were founded with different views, and in a different age of the Roman hiſtory, from the ſettlements in the provinces.

M. Vaillant has filled a volume in folio with medals ſtruck by the ſeveral colonies, in honour of the emperors who founded them. The ordinary ſymbol they engraved on their medals was either an eagle, as when the veteran legions were diſtributed in the colonies; or a labourer holding a plough drawn by a pair of oxen, as when the colony conſiſted of ordinary inhabitants. On all the medals are ſeen the names of the Decemviri, who held the ſame rank, and had the ſame authority there as the conſuls had at Rome.

In the political relations of the Roman ſettlements with their parent city, there is ſome reſemblance to the political relations of modern colonies with their mother countries. But in the policy of a ſtate ſo neglectful of every thing, except war, we cannot expect to find any parallel to thoſe commercial views, by which the plantation of modern colonies has been undertaken, and their connexion with the European governments maintained. The objects of the Romans, in planting their colonies, were conqueſt and plunder; ſo that detachments of emigrants incorporated with, and governed, the old poſſeſſors of the ſoil. In modern times the chief objects have been trade and agriculture; the moſt important ſettlements have been made in deſert countries, or diſtricts, whoſe ancient inhabitants were extirpated by the firſt ſettlers. In this reſpect then, the Roman colonies rather bear a reſemblance to the Aſiatic eſtabliſhments of modern Europe; but they differ from theſe too, in the ſtructure of their government. The conſtitution of the Italian colonies was formed upon the Roman model, and varied with its changes. The provincial governments of Hindooſtan, and the iſlands of the Indian ocean, very little reſemble thoſe of their European maſters, and are rather allied to the ſpirit of the oriental legiſlation. The provincial governments of the Roman tranſmarine territories bore, in every reſpect, the ſame kind of relation to the metropolis, which the Eaſt Indian eſtabliſhments do to the ſtates of Europe. The inhabitants retained, in a great degree, their own laws; they were ruled and oppreſſed by a Roman magiſtrate, and an army, compoſed partly of Roman, partly of native troops; their country was the ſcene of every criminal exceſs in politics and manners, and the ſource of large ſupplies to the plunderers of the world.

The ſpecies of colonies now deſcribed is not reſtricted to the Romans, but it has been adopted by almoſt every nation, both ancient and modern, with very little variation. To it we may refer the eſtabliſhment of the Normans in England, and of the Engliſh in Ireland. In a ſtill later period, the Portugueſe and Dutch have eſtabliſhed themſelves in India; but the Engliſh Eaſt India company have, on the contrary, repreſſed, as far as poſſible, the colonization of the countries they poſſeſs there, as theſe directors obſerve that "the energy of the European character becomes obliterated in the courſe of a few generations."

The commerce of Carthage, together with her extenſive continental poſſeſſions, enabled her to provide for her increaſing population at home. The want of an outlet for inhabitants formed no part of the motives that induced the Carthaginians to ſettle foreign colonies. Their colonial eſtabliſhments, indeed, were moſt probably founded in the ſame manner with the tranſmarine and tranſalpine provinces of the Romans;—conquered countries, retained in ſubjection, from ambition and pride, by means of a Carthaginian governor, and a few followers, prompted by idleneſs, or the love of change, or the deſire of diſtinction to follow in his retinue. However, the relations of the new eſtabliſhments with the mother country were different, in ſeveral reſpects, from the relations which connected the diſtant parts of the Roman dominions with the metropolis. The Carthaginian colonies were, in reality, trading correſpondents to the mother country; and ſhould have found a place under the 4th claſs of colonies rather than here, if they had not been immediately connected with the Roman. It is probable that the Carthaginians received the ſurplus of the rude produce of Sicily, Sardinia, and Spain, which Africa did not yield, and exported thither thoſe manufactures, which would naturally be raiſed in a country fully peopled, and long habituated to traffic. From the ſuperiority of their navigation too, the ſkill of the Carthaginian merchants, their connexions long eſtabliſhed with the Levant, more particularly with the great emporiums of the Eaſt, Tyre and Smyrna, and from the greater trading capitals of thoſe rich merchants; they would moſt likely furniſh the colonies or provinces with Aſiatic commodities, of which Carthage would be the natural entrepôt for the countries to the weſt of the Mediterranean. Hiſtory has preſerved two treaties of commerce and navigation between the Carthaginians and Romans, conceived in the true ſpirit of the modern colonial policy; for which ſee Polyb. l. iii. c. 22. or Brougham's Colonial Policy, &c. vol. i. p. 21, &c.

In this connection we might mention another ſpecies of external colonies, produced by the diſpoſſeſſion of weaker ſtates by thoſe who are ſtronger, in order to extend their borders, or to poſſeſs ſome advantageous ſituations for trade, or for war. The bigotry of the Europeans, at the time of the diſcovery of the Weſt Indies, led them to look upon the natives of thoſe countries in a very unfavourable and contemptuous light, on account of their being heathens and idolaters, and made them heedleſs as to the meaſures they adopted for their own ſecurity, ſo that they could but obtain the object of their wiſhes. The great diſproportion alſo in the numbers of the invaders and of the natives, in ſome meaſure, impelled the Europeans to adopt the moſt ſevere methods, to perpetuate the terror which the natives had originally manifeſted at the effects of their fire-arms. The conſequence of thoſe ſeverities was, that the natives of moſt of the iſlands were ſoon exterminated, except in ſome very ſmall ones which the Europeans left unnoticed. On the continent, however, the natives ſtill exiſt, as they have there ſufficient ſpace to retire from the neighbourhood of their viſitors.

To the *third* claſs belong thoſe colonies that have been formed by refugees from countries, in which they were oppreſſed or perſecuted. Thus the emigrants, who fled from the religious broils in which France, the Low Countries, and Germany have been involved, found ſafety in England, and introduced many of thoſe manufactures and arts, which have contributed to the commercial ſuperiority of Great Britain. Norwich, Canterbury, and even ſome of the moſt populous diſtricts of the metropolis, have owed the induſtry and productions of their inhabitants to theſe colonies; and, in like manner, part of Pembrokeſhire, in South Wales, has been peopled by a colony from Flanders. The colonies of North America were originally planted by men who had quitted their native country, either from a love of civil and religious liberty; or from a deſire to better their fortunes, by laying out a ſmall capital in the improvement of land; or from the neceſſity of finding employment in a country where labour bore a high price. Anxious only to live in peace and freedom, with a competency for themſelves and their families; theſe men centered all their views in the ſpot to which they removed their fortunes and perſons; they gave up for ever the thoughts of returning to the countries which they left behind them; and transferred to their new homes all thoſe ties which had formerly bound them to Europe. The woods of the northern continent were cleared by men of ſmall capital content with a living profit, attached to the ſoil, which owed its cultivation to their labours, and entertaining no idea of removing from it. By degrees the influence of local attachment binds them to a ſpot, which neceſſity had made the object of their choice; and in proceſs of time the deſire of depoſiting their bones in a country which had received and cheriſhed them, ſucceeded to the obliterated partiality for the place of their birth. The firſt ſettlers of all the colonies of N. America were men of irreproachable characters, though not very enlightened in their views, or poliſhed in their manners. Many of them fled from perſecution; others on account of an honourable poverty; and all of them with their expectations limited to the proſpect of a bare ſubſiſtence in freedom and peace. The greater part of them viewed their emigration beyond the Atlantic, as a taking up of the croſs; and bounded their hopes of riches to the gifts of the ſpirit, and their ambition, to the deſire of a kingdom beyond the grave. A ſet of men more conſcientious in their doings, or ſimple in their manners, never founded any commonwealth. It is, indeed, the peculiar glory of N. America, that, with a very few exceptions, its empire was originally founded in charity and peace. In proceſs of time, however, new emigrants

grants flocked to this extenſive country, as it became more open and improved, whoſe views, principles, and character were very different from thoſe of the firſt ſettlers. Many of them were perſons in very indigent circumſtances; they were of different ſects, or of no perceptible religion at all; and of different nations, though the Engliſh greatly predominated. Some of them were convicts, who after confinement in goals were baniſhed for their crimes; many of them perſons of deſperate fortunes, to whom every place was equally uninviting; or men of notoriouſly abandoned lives, to whom any region was acceptable, that offered them a ſhelter from the vengeance of the law, or the voice of public indignation. But a change of ſcene would naturally produce ſome ſalutary effect upon characters the moſt diſſolute. This mixture of various population was ſoon blended, by the influence of thoſe ſimple manners that are formed by an agricultural life, into one nation of huſbandmen, whoſe character has communicated itſelf, in a great degree, to the moſt profligate of thoſe whom compulſion or deſpair from time to time introduced. While purity of manners was in this way preſerved, that firmneſs of principles in religion and politics was maintained, which had ſo eminently contributed to the eſtabliſhment of the colonies. Sentiments of freedom might find an aſylum in America, when, even in Swiſſerland, it ſhould no longer be lawful to think beyond the rules. Neverthele ſs, the circumſtances of the N. American colonies produced ſome other effects not quite ſo favourable, upon the taſte, and in what, in common converſation, we call the manners of the people. The ſolitary nature of agricultural labour, and the ſecluſion of the huſbandman's reſidence, ſurrounded only by his own family and ſervants, are very inimical to all ſorts of refinement, and to every ornamental accompliſhment; whilſt the ſettlers of the new colonies were occupied with the uſeful, they neglected the agreeable arts of life; and voluntarily threw themſelves back ſome centuries, in moſt branches of civilization, inſtead of proſecuting the improvements of thoſe branches, from the point to which the mother country had brought them at the æra of their emigration. In conſequence of their peculiar circumſtances and occupations, the Americans have always poſſeſſed a numerous, virtuous, and athletic peaſantry; but they have numbered few fine artiſts, or accompliſhed orators; and, indeed, an ingenious writer, to whom we are much indebted in the compilation of this article, proceeds ſo far as to obſerve, with a latitude of expreſſion ſcarcely allowable, that "the word American has never yet (ſo far as I know) been coupled with either poetry, or painting, or muſic." The hiſtory of manners in N. America, ſays this writer, is the general hiſtory of manners in every new community, of which agricultural induſtry forms the baſis. The peculiarities (perhaps accidental), which marked the ſituation and habits of the firſt ſettlers, have likewiſe produced ſome effect upon thoſe of their deſcendants, without in the leaſt modifying their character as an agricultural nation. The love of civil and religious freedom was connected with an anxious attention to all matters of controverſy, whether in politics or in faith; and as the ſettlers were equally incapable of underſtanding either, ſo they were chiefly captivated with the more abſtruſe of the two ſciences; and affected great depth in the things appertaining to grace, ſpirit, incarnation, and all the ſublime myſteries of the Chriſtian diſpenſation. Theſe fruitleſs ſpeculations were the only literary inheritance which they tranſmitted to their children. But although they had left the old world for the ſake of liberty of conſcience, they too ſoon manifeſted what they underſtood by liberty of conſcience. By that term they meant (like many other advocates of liberty) the propagation of their own peculiar tenets; and they ſhewed that they only wanted the power to propagate their creed (like their European oppreſſors) by that method of mental perſuaſion which conſiſts in burning the body. They allowed every man entire liberty of conſcience, provided that he uſed that liberty in adopting their own ſtandard of faith. Accordingly, while in Old England the ſpirit of fanaticiſm was operating the downfal of government, and mingling itſelf with every purſuit of the age, to the univerſal debaſement of manners and ſentiment; in New England, the heterodox were perſecuted by the impulſes of the inward light; or parties were formed, and armies marſhalled, and millions led by the ſubtle principles of a metaphyſical theology. But the Falklands and Sydneys had no parallels to temper the unclaſſical rage of the American bigots; and even the Cromwells and Bradſhaws found but poor repreſentatives in the ſtupid fanatics of Boſton and Salem. Long after the mother country had relinquiſhed, for ever, the acts of perſecution, they found votaries in the conſtituted authorities of the colonies; and the northern ſtates at the end of the 17th century, afforded the diſgraceful example of that ſpiritual tyranny, from which their territories had originally ſerved as an aſylum. The century, which has juſt elapſed, moderated this odious ſpirit; but to this day, the northern ſtates are chiefly diſtinguiſhed from the others, by a taint of religious bigotry;—as the character of the middle ſtates is modified by the greater mixture of different nations, which have contributed to people them;—and that of the ſouthern provinces, by the admixture of negro ſlaves. In the middle ſtates, the mercantile ſpirit has gained more ground than in any of the reſt: the diverſities of race have rendered the ſentiments of patriotiſm, and the love of liberty, leſs ardent; while the variety of religions has prevented the introduction of that fanaticiſm, of which we have traced the effects in the north. In the ſouthern ſtates the contraſt of ſervitude has mingled an ariſtocratical ſpirit with the manners of ſimple huſbandmen; and the climate, by promoting the growth of an article, belonging to the claſs of luxuries, has given riſe to a ſpecies of agriculture bordering upon the great gains and uncertain proſpects of commercial ſpeculation. In all the colonies, however, of the northern continent, a reſpectable national character may be ſaid to prevail. If their intercourſe with the mother country would have had no tendency to civilize or adorn her, it could certainly have in no degree contributed to the corruption, either of her moral or political habits; and the moſt rapid interchange of population could only have tended to embelliſh the American ſociety and to vary its accompliſhments, while it rendered a ſervice to the Britiſh manners, by the intercourſe of a more ſimple and virtuous people. Unfortunately, the very circumſtances which neceſſarily laid the foundation of thoſe habits and that national character inſulated the population of the country from that of the old world. The colonies were ſtationary for the ſame reaſon that they were reſpectable; and the circulation of its inhabitants, with all its effects upon both parts of the empire, has been maintained and accelerated in other colonies, placed in circumſtances which rendered thoſe effects unfavourable, at leaſt to the mother country. For the change that has taken place with regard to the principles and manners, the religion and liberty of the ſeveral colonies of N. America, ſince they have acquired a new government, and been formed into the *United States*; ſee this article, and alſo an account of the ſeveral ſtates themſelves under their appropriate titles.

The *fourth* claſs of colonies comprehends thoſe that are denominated *commercial*, and which have been eſtabliſhed at different periods, by the Engliſh, Dutch, French, Spaniards, Portugueſe, and other nations; and which are ſtill maintained, in a greater or leſs degree, with a view of keeping up a regular intercourſe with the natives, or of cultivating the ground, by planting ſugar-canes, rice, indigo, tobacco, cotton and other commodities. See CHARTER *Governments*.

The principal of this kind of colonies are thoſe that have been eſtabliſhed in North and South America; particularly Peru, Mexico, Canada, Virginia, New England, Carolina, Louiſiana, Hudſon's bay, the Antilles iſlands, Jamaica, Domingo, and the other iſlands of the Weſt Indies: alſo, in Africa, Madagaſcar, the cape of Good Hope, cape Verd, and its iſlands, and all the coaſts extended thence as far as to the Red ſea; and likewiſe in Aſia, the famous Batavia of the Dutch, and Ceylon; Goa, Diu, of the Portugueſe; and ſome other leſs conſiderable places of the Engliſh, French, Danes, and other nations, in the Eaſt and Weſt Indies.

The eſtabliſhment of the European colonies in America and the Weſt Indies, if we except thoſe of North America to which we have already alluded, did not originate in neceſſity; but it was the reſult of ambitious and intereſted views. The Dutch, indeed, may plead in favour of the extenſion of their own ſettlements and commerce, that the colonial ſyſtem is neceſſary to their ſubſiſtence and proſperity. Their territory is ſmall, and generally undiſtinguiſhed by its fertility; and therefore they have recurred for the neceſſaries of life to the ports of more fruitful and leſs populous countries. Habituated to induſtry, and excelling other nations in nautical ſkill, inſtead of confining themſelves to the exchange of their own manufactures for the rude produce, or the manufactures of other nations, they employed themſelves in circulating the produce and manufactures of other countries; and, more attentive to this occupation than to the arts of working up the produce which they imported or raiſed, they became a nation, not of farmers or manufacturers, but of fiſhermen, merchants, and ſailors. Conſtrained by other circumſtances belonging to their country, when compared with other nations, they were obliged, by the diſadvantages of their ſituation and the oppreſſion of their Spaniſh maſters, to put forth every poſſible effort of fortitude and perſeverance. By induſtry, frugality, and labour, theſe people not only ſoon outſtripped all their contemporaries in riches and naval ſkill, but amaſſed a much greater ſhare of wealth, and gained a more formidable influence over the deſtinies of the world, than ſo ſmall a tribe ever acquired in any age. Their ſteady attachment to the principles of freedom and toleration ſerved as a concurring mean of their advancement and proſperity. The neceſſary conſequence of extenſive opulence, acquired by a people who have not a proportionably great territory, is, that the means of advantageouſly employing their capital will become gradually more and more difficult; the profits of its employment more confined, and its accumulation more ſlow. Such a people will naturally ſeek ſome new opening for ſettlement or commerce, by acquiring territory in diſtant quarters of the globe. Should they fail in this way, the overflowing wealth of the nation muſt infallibly emigrate, as it were, into the ſervice of foreign countries, where the profits are greater than they are at home. Hence we find that the Dutch became, in a ſenſe, the brokers of Europe; and that they advanced ſums to foreign ſtates and their ſubjects, which were enormous. It is probable, ſays an ingenious and accurate writer, (Mr. Brougham), that the Dutch have frequently been creditors, at one time, to the amount of much more than 300 millions ſterling to their own government, and to foreign ſtates, of which we may reckon two-thirds in foreign loan: an immenſe ſum of ſurplus capital to have been accumulated by a nation poſſeſſed of no greater territory than the principality of Wales, without any good harbours, or any natural produce fit for exportation; a territory, 120 times leſs extenſive than the European dominions of Ruſſia, which is conſtantly running in debt with all the world! A people poſſeſſed of ſuch an overflowing capital, was, of all people, that which ſtood the moſt in need of foreign colonies; and this for two reaſons:—in order to obtain a new opening, of whatever kind, for the ſtock which could not be employed at home, or which, for want of this employment, was drawn into the ſervice of foreigners; and in order to ſecure the poſſeſſion of this opening at all times under its own command. The acquiſition of colonial poſſeſſions is the only means by which the United Provinces can poſſibly avoid the decline of its mercantile proſperity and political importance, and ſupply their natural deficiency of territory, the cauſe of their inſtability, as it was the cauſe of their riſe and progreſs. An opening for capital may then be obtained always under the command of the ſtate. The poſſeſſion of colonies muſt be as advantageous to the community of the United Provinces, as agreeable to individual capitaliſts and adventurers. It has certainly preſerved the commercial exiſtence of the republic for a long ſeries of years, and enabled this ancient ſtate to retain its place among the great powers of Europe inſtead of being ſwallowed up by its neighbours, or reduced to a few fiſhing villages. No nation of Europe depends ſo much upon colonial policy as Holland; nor is any ſo liable to be affected, in every member, by the ſlighteſt variation of colonial affairs. See *Dutch Eaſt India* COMPANY and *Dutch Weſt India* COMPANY. The whole return of the Dutch colonies, above 20 years ago, was calculated (ſays Mr. Brougham) at 24 millions of florins—exported in 150 veſſels, navigated by 1000 men, and paying, in freight, 4 millions 5 hundred thouſand florins—in commiſſion and inſurance, 2½ millions. The Dutch merchants exported to them merchandize (including negro ſlaves) to the value of 6 millions. The moſt unfortunate circumſtance in the colonial policy of the Dutch has always been their bad treatment of ſlaves. (See NEGROES and SLAVES.) The colonies of Holland have alſo ſuffered, in general, from the importation of negroes being too ſcanty to anſwer the demands of the proprietors. Upon the whole, it is obſerved by the writer ſo often cited in this article, that in no country is there ſo great a demand for new colonies as in the United Provinces. To no part of Europe are colonial poſſeſſions ſo valuable; none would be ſo irretrievably ruined by their loſs; none would be ſo much benefited by their extenſion.

The views of Spain in its colonial eſtabliſhments were directed from the beginning of their connection with America to the pecuniary advantages likely to reſult from them. In conſequence of the repreſentation of Columbus, the council of Caſtile determined to take poſſeſſion of countries of which the inhabitants were incapable of defending themſelves. The pious purpoſe of converting them to Chriſtianity ſanctified the injuſtice of the project. But the hope of finding treaſures of gold there was the ſole motive which prompted them to undertake it; and to give this motive the greater weight, it was propoſed by Columbus, that the half of all the gold and ſilver which might be found there ſhould belong to the crown. This propoſal was approved of by the council. The tax was eaſily paid whilſt the defenceleſs natives were plundered; but as they were ſtripped of all that they had, which, in St. Domingo, and the other countries diſcovered by Columbus, was completely done in ſix or eight years; and when it became neceſſary to dig for it in the mines, it was impoſſible to pay the tax. The rigorous exaction of it occaſioned firſt the total abandonment of the mines of St. Domingo, which have never been wrought ſince; and it was afterwards reduced, by ſucceſſive defalcations, to a 20th part of the produce of the gold mines. The tax upon ſilver, which was a fifth of the groſs produce, was reduced to a tenth in the courſe of the laſt century. All the other enterpriſes of the Spaniards in the New World, ſubſequent to thoſe of Columbus, ſeem to have been prompted by the ſame motive. It was the ſacred thirſt of gold that carried Oieda, Nicueſſa, and Vaſco Nugnes de Balboa, to the iſthmus of Darien, that carried Cortez to Mexico, and Almagro and Pizarro to Chili and Peru. Impelled by the proſpect of immenſe gain to eſtabliſh colonies in America, the firſt object of the Spaniſh monarchs was to ſecure the productions of theſe colonies to the parent ſtate, by an abſolute prohibition of any intercourſe with foreign nations. They took poſſeſſion of America by right of conqueſt; and, having reaſon to apprehend the loſs of their infant ſettlements, on account of their feebleneſs, their extent, and the reluctance with which the vanquiſhed nations ſubmitted to their dominion, they guarded, by every poſſible method, againſt the intruſion of ſtrangers. As their poſſeſſions were extended, the ſpirit of jealouſy and excluſion increaſed; and, in order to their greater ſecurity, a ſyſtem of colonizing was introduced, to which the hiſtory of mankind afforded no parallel. In the ancient world, as we have already ſeen, colonies were of two kinds; either migrations from a country overſtocked with inhabitants, or military detachments, ſtationed as garriſons in a conquered province. The colonies of ſome Greek republics, and the ſwarms of northern barbarians which ſettled in different parts of Europe, were of the firſt kind; and the Roman colonies were of the ſecond kind. In the former, the connection with the mother country quickly ceaſed, and they became independent ſtates; in the latter, the dependence continued, becauſe the ſeparation was not complete. The Spaniſh monarchs, in their American ſettlements, took what was peculiar to each, and ſtudied to unite them. By ſending colonies to regions ſo remote, by eſtabliſhing in each a form of interior policy and adminiſtration, under diſtinct governors, and with peculiar laws, they disjoined them from the mother country. By retaining in their own hands the rights of legiſlation, as well as that of impoſing taxes, together with the power of nominating the perſons who filled every department, civil or military, they ſecured their dependence. At firſt, as we have already obſerved, the precious metals were the only objects that attracted their attention. Afterwards they ſought for ſuch productions of the climate as, from their rarity or value, were of chief demand in the mother country; and they forbade the eſtabliſhment of ſeveral ſpecies of manufacture, that were likely to interfere with thoſe of the mother country. Their clothes, furniture, inſtruments of labour, luxuries, and even a conſiderable part of the proviſions which they conſumed, were imported from Spain. In return, the coloniſts ſupplied the produce of their mines and plantations, which was conveyed only in Spaniſh bottoms. The commercial intercourſe of one colony with another was either abſolutely prohibited, or limited by many jealous reſtrictions. All that America yields flows into the ports of Spain; all that it conſumes muſt iſſue from them. No foreigner can enter its colonies without expreſs permiſſion; no veſſel of any foreign nation is received into their harbours; and the pains of death, with confiſcation of moveables, are denounced againſt every inhabitant who preſumes to trade with them. Thus the colonies are kept in a ſtate of perpetual pupillage; and by the introduction of this commercial dependence, a refinement in policy, of which Spain ſet the firſt example to the European nations, the ſupremacy of the parent ſtate hath been maintained over remote colonies, during 2½ centuries. Several maxims were alſo adopted and enforced with regard to the reſtrictions of ſettlers, the ſtate of property, and the eccleſiaſtical policy of the colonies, which ſerved very much to diſcourage emigration from Europe, and the increaſe of population in America. If we advert to the ſtate of Spain, and compare it with that of Holland, we ſhall ſoon perceive, that the Spaniards, poſſeſſing a country fifteen times more extenſive than Holland, of incalculably greater fertility, enjoying all the benefits of the fineſt climate in the world, ſurrounded with natural barriers of defence, and bleſſed with every advantage of ſituation which can facilitate commercial intercourſe, and yet maintaining not much more than one-fourth of the Dutch population, are evidently independent of colonial poſſeſſions. All the induſtry, ſkill, and capital of the natives, may find ample employment in raiſing, manufacturing, and circulating the produce of the ſoil, or in exchanging the ſuperfluous part of that produce for the commodities which abound in other countries. But, though it would have been ſounder policy in the Spaniſh government to have promoted a ſpirit of induſtry at home, than to have eſtabliſhed diſtant colonies, yet it cannot be denied, that ſhe has received very great benefits from them, and ſuch, in their nature and value, as more than counterbalance the injury they have occaſioned. At the period of their firſt eſtabliſhment, the interior induſtry and manufactures of Spain were ſo proſperous, that, with the product of theſe, ſhe was able both to purchaſe the commodities of the New World, and to anſwer its growing demands. Under the reigns of Ferdinand and Iſabella, and Charles V., Spain was one of the moſt induſtrious countries in Europe. Her manufactures in wool, and flax, and ſilk, were ſo extenſive, as not only to furniſh what was ſufficient for her own conſumption, but to afford a ſurplus for exportation. When a market for them, formerly unknown, and to which ſhe alone had acceſs, opened in America, ſhe had recourſe to her domeſtic ſtore, and found there an abundant ſupply. By this new demand, furniſhing anſwerable employment, the ſpirit of induſtry muſt have been enlivened and encouraged; and the manufacture, population, and wealth of Spain might have gone on increaſing in the ſame proportion with the growth of her colonies. However, by the great and ſudden augmentation of power and revenue, which the poſſeſſion of America brought into Spain, ſober plans of induſtry were overturned, and opulence, rapidly acquired, produced a taſte for what is wild and extravagant, and daring in buſineſs or in action. The genius of Charles V in ſome meaſure counteracted the pernicious influence of this inundation of wealth and of the ſubſequent interruption of it; but under Philip II. its effect, both on the monarch and the people, became conſpicuous. Philip, poſſeſſing an extravagant opinion of his inexhauſtible reſources, and, at the ſame time, an ambition connected with moderate talents, thought himſelf equal to any undertaking. Accordingly he waged open war with the Dutch and Engliſh, encouraged and aided a rebellion in France, conquered Portugal, and maintained armies and garriſons in Italy, Africa, and both the Indies. Thus Spain was drained both of men and of money. Under the weak adminiſtration of his ſucceſſor, Philip III., the vigour of the nation declined, and the bigotry of the monarch expelled near a million of his moſt induſtrious ſubjects; ſo that early in the 17th century, Spain felt ſuch a diminution in the number of her people, that from inability to recruit her armies, ſhe was obliged to contract her operations. Her flouriſhing manufactures were fallen into decay. Her fleets, which had been the terror of all Europe, were ruined. Her extenſive foreign commerce was loſt. Agriculture was neglected, and one of the moſt fertile countries in Europe hardly raiſed what was ſufficient for the ſupport of its own inhabitants. In proportion as the population and manufactures of the parent ſtate declined, the demands of her colonies continued to increaſe. The rage of emigration prevailed, and the ſtrength of the colonies was augmented by exhauſting that of the mother-country. The emigrants depended upon Spain for almoſt every article of neceſſary conſumption. But Spain, thinned of people and deſtitute of induſtry, was unable to ſupply their increaſing demands. She had recourſe to her neighbours; and the manufactures of the Low Countries, of England, of France, and of Italy, which her wants called into exiſtence, or animated with vivacity, furniſhed in abundance whatever ſhe required. In a ſhort time not above one-twentieth part of the commodities exported to America was of Spaniſh growth or fabric. All the reſt was the property of foreign merchants, though entered in the name of Spaniards; ſo that the treaſure of the New World may be ſaid henceforward not to have belonged to Spain. Before it reached Europe, it was anticipated as the price of goods purchaſed from foreigners. Thus the poſſeſſions of Spain in America have not ſerved as a ſource of population and of wealth to her, in the ſame manner as thoſe of other nations. From the cloſe of the 16th century ſhe was unable to ſupply the growing wants of her colonies; and the pernicious effects of this diſproportion between their demands and her capacity of anſwering them, were farther aggravated by the mode in which ſhe endeavoured to regulate the intercourſe between the mother-country and the colonies. Such was the monopoly at which ſhe aimed, and which ſhe wiſhed to maintain, that ſhe did not veſt her trade with her colonies in an excluſive company; a plan which had been adopted by nations more commercial, and at a period when mercantile policy was an object of greater attention, and ought to have been better underſtood. The Dutch gave up the whole trade with their colonies both in the Eaſt and Weſt Indies, to excluſive companies. The Engliſh, French, and Danes, have imitated their example with reſpect to their Eaſt-Indian commerce; and the two former have laid a ſimilar reſtraint upon ſome branches of their trade with the New World. The wit of man cannot, perhaps, deviſe a method for checking the progreſs of induſtry and population in a new colony, more effectual than this. From this error in policy Spain was preſerved, probably by the high ideas which ſhe early formed concerning the riches of the New World. Gold and ſilver were commodities of too high value to veſt a monopoly of them in private hands. The crown retained this alluring branch of commerce; and in order to ſecure it, enjoined the cargo of every ſhip fitted out for America to be inſpected by officers at Seville, and then to receive a licence for the voyage; and on its return, that a report of the commodities which it brought ſhould be made to the ſame board, before it ſhould be permitted to land them. By this regulation all the trade of Spain with the New World centered in the port of Seville, and was brought into a form, in which it has been continued with little variation, almoſt to our own times. See GALEONS and FLOTA.

The trade of Spain with her colonies being thus reſtricted, was conducted on the ſame principles which directed that of an excluſive company; and the whole of it was exported by a few wealthy houſes, formerly in Seville, and ſince the year 1720 in Cadiz; theſe, by combinations eaſily formed, prevent that competition which preſerves commodities at their natural price; and, by acting in concert, to which mutual intereſt prompts them, they may raiſe or lower the value of them at pleaſure. This reſtraint of the American commerce to one port, not only affects its domeſtic ſtate, but limits its foreign operations. In theſe circumſtances, and whilſt the evils reſulting from them found no effectual remedy, Spain, with dominions more extenſive and more opulent than any European ſtate, poſſeſſed neither vigour, nor money, nor induſtry. At length the violence of a great national convulſion rouzed the ſlumbering genius of Spain. As ſoon as the Bourbons acquired poſſeſſion of the throne, it was the firſt object of Philip V. to prohibit the admiſſion of foreign veſſels into any port of Peru and Chili; and a Spaniſh ſquadron was employed to clear the South Sea of intruders, whoſe aid was no longer neceſſary. After the treaty of Utrecht, which terminated the war, new embarraſſments occurred in conſequence of the aſſiento, or contract for ſupplying the Spaniſh colonies with negroes, conveyed to Great Britain, as the price of peace; (See ASSIENTO) and the additional privilege of ſending annually to the fair of Porto-Bello, a ſhip of five hundred tons, laden with European commodities. By the operations that ſucceeded theſe grants, and by the activity of private interlopers, almoſt the whole trade of Spaniſh America was engroſſed by foreigners. Guarda coſtas, and regiſter ſhips were introduced. (See each of theſe articles). Since the reign of Philip V., ſentiments with regard to commerce, more liberal and enlarged, began to ſpread in Spain. At length Charles III. in 1764, appointed packet-boats to be diſpatched on the firſt day of each month, from Corugna to the Havannah or Porto-Rico. From thence letters are conveyed in ſmaller veſſels to Vera-Cruz and Porto-Bello, and tranſmitted by poſt through the kingdoms of Terra Fermé, Granada, Peru, and New Spain. Other packet-boats ſail regularly once in two months, to Rio de la Plata, for the accommodation of the provinces to the eaſt of the Andes. With this new arrangement for conveying ſpeedy and regular intelligence, a ſcheme of extending commerce has been more immediately connected. Each packet boat is a trading veſſel, and is uſed for facilitating the exchange of Spaniſh product, for an equal quantity of that of America. This was ſoon followed by a greater degree of enlargement. In the year 1765, Charles III. laid open the trade to the windward iſlands, Cuba, Hiſpaniola, Porto-Rico, Margarita, and Trinidad, to his ſubjects in every province of Spain. He reduced the duties on goods exported to America, to the moderate tax of ſix in the hundred, on the commodities ſent from Spain. He allowed them to return to any port at pleaſure. This ample privilege was afterwards extended to Louiſiana, and to the provinces of Yucatan and Campeachy. Such have been the benefits experienced from the relaxation of the ancient ſyſtem of commerce between the mother-country and her colonies, that Spain has been induced to permit a more liberal intercourſe of one colony with another. In 1774 Charles III. publiſhed an edict, granting to Peru, New Spain, Guatimala, and Granada, the privilege of a free trade with each other. The towns to which Spain has granted the liberty of trade with any of her colonies, are Cadiz and Seville, for the province of Andaluſia; Alicant and Carthagena, for Valencia and Murcia; Barcelona, for Catalonia and Arragon; Santander, for Caſtile; Corugna, for Galicia; and Gijon, for Aſturias. Theſe are either the ports of chief trade in their reſpective diſtricts, or thoſe moſt conveniently ſituated for the exportation of their reſpective productions. Prior to the allowance of free trade, the duties collected at the Cuſtom-houſe at the Havannah, were computed to be 104,208 peſos annually. During the five years preceding 1774, they roſe at a medium to 308,000 peſos a year. In Yucatan, the duties have riſen from 8,000 to 15,000. In Hiſpaniola, from 2,500 to 5,600. In Porto-Rico, from 1,200 to 7,000. The total value of goods imported from

Cuba into Spain, was reckoned, in 1774, to be 1,500,000 peſos. From another ſtatement, it appears, that the exports to Spaniſh America in 1778, were made in 170 ſhips; were worth about 74 millions of reals vellon, and paid above 3½ millions of duty. The imports from thence, in the ſame year, were made in 130 ſhips, valued at 74½ millions, and paid nearly 3 millions duties. In 1788, the value of the exports had riſen to above 300 millions, and that of the imports to above 804½ millions. The duties upon both exports and imports exceeded 55 millions. This rapid increaſe can be aſcribed to nothing but the effects of the free trade; and notwithſtanding all the clamours raiſed by the Cadiz merchants, we find that this city was the firſt to enjoy the advantage of the change; for the imports of Cadiz from America in 1788, were three-fourths of the whole colonial imports; and the exports of Cadiz thither were conſiderably above two-thirds of the whole colonial exports. Spain has likewiſe directed particular attention to the interior government of her colonies. For an account of the Philippine colony, ſee ACAPULCO and MANILA.

The revenues which Spain derives from America, ariſes from taxes of various kinds, which may be divided into three capital branches. The firſt contains what is paid to the king, as ſovereign of the New World; to this belongs the duty on the gold and ſilver raiſed from the mines, and the tribute exacted from the Indians; the former called "the right of ſigniory," and the latter "the duty of vaſſalage." The ſecond branch comprehends the numerous duties upon commerce, which are very minute and oppreſſive. The third includes what accrues to the king, as head of the church, and adminiſtrator of eccleſiaſtical funds in the New World. In conſequence of this he receives the firſt-fruits, annats, ſpoils, and other ſpiritual revenues, levied by the apoſtolic chamber in Europe; and is entitled likewiſe to the profit accruing from the bull of *Cruzado*, which ſee. The whole amount of the net public revenue of Spain, raiſed in America, is ſtated by Dr. Robertſon as not exceeding a million and a half ſterling. Spain and Portugal are the only European powers which derive a direct revenue from their colonies, as their quota towards defraying the general expence of government. All the advantage, that accrues to other nations from their American dominions, ariſes from the excluſive enjoyment of their trade; but, beſides this, Spain has brought her colonies to contribute towards increaſing the power of the ſtate, and, in return for protection, to bear a proportional ſhare of the common burden. The amount of the Spaniſh revenue, above ſtated, comprehends only the taxes collected there, and is far from being the whole of what accrues to the king from his dominions in the New World. The heavy duties impoſed on the commodities exported from Spain to America, as well as what is paid by thoſe which ſhe ſends home in return; the tax upon negro ſlaves, with which Africa ſupplies the New World, together with ſeveral ſmaller branches of finance, bring larger ſums into the treaſury, the preciſe extent of which Dr. Robertſon cannot pretend to aſcertain. But if the revenue which Spain draws from America be great, the expence of adminiſtration in her colonies bears proportion to it.

The total amount of the public revenue of Spain from America and the Philippines, from the moſt recent information ſtated by Dr. Robertſon, is as follows:

Alcavalas (exciſe) and aduanas (cuſtoms), &c. in peſos fuertes, - - -	2,500,000
Duties on gold and ſilver, - -	3,000,000
Bull of Cruzado, - - -	1,000,000
Tribute of the Indians, - -	2,000,000
By ſale of quickſilver, - -	300,000
Paper exported on the king's account, and ſold in the royal warehouſes, - -	300,000
Stamped paper, tobacco, and other ſmall duties,	1,000,000
Duty on coinage of, at the rate of one real de la Plata, for each mark, - -	300,000
From the trade of Acapulco, and the coaſting trade from province to province, -	500,000
Aſſiento of negroes, - - -	200,000
From the trade of *Mathé*, or herb of Paraguay, formerly monopolized by the Jeſuits, -	500,000
From other revenues formerly belonging to that order, - - - -	400,000
Total	12,000,000
Total in ſterling money	£ 2,700,000
Deduct half, as the expence of adminiſtration, and there remains net free revenue, -	£ 1,350,000

From the above detail, and upon a general view of the ſubject, it appears to be abſurd to deny, that Spain has derived very great benefits from her colonial poſſeſſions. Nevertheleſs, many very enlightened men have maintained, that the downfal of the Spaniſh power has been owing, in a great meaſure, to the extenſion of dominion which followed the diſcovery of America. To this purpoſe an appeal has been made to the authority of Dr. Smith, the well known and much approved author of the "Wealth of Nations." "That the monopoly," he obſerves, "of the trade of populous and thriving colonies is not alone ſufficient to eſtabliſh, or even to maintain, manufactures in any country, the examples of Spain and Portugal ſufficiently demonſtrate. Spain and Portugal were manufacturing countries before they had any conſiderable colonies. Since they had the richeſt and moſt fertile in the world, they have both ceaſed to be ſo." However, Mr. Brougham has remarked, that the tenor of this obſervation is confined to the ſtatement of a fact which cannot be denied, that the period of the decline which the Spaniſh and Portugueſe manufactures have experienced, coincided with the period of the Spaniſh and Portugueſe colonial greatneſs. But the whole argument proceeds upon a view of the ſubject, formerly diſcuſſed, that colonial monopolies in general have been hurtful, from their effects on the wealth of the mother-country. Mr. Brougham has accurately examined this ſubject; and in the proſecution of his inquiry, he has ſhewn, in what manner the proſperity of Spain has been influenced by the diſcovery of America; and he has inveſtigated the queſtion, whether the acquiſition of rich and extenſive colonies can be charged with having cauſed the decline of the mother-country, and whether, in ſhort, any bad conſequence whatever is imputable to this augmentation of empire.

By thoſe who have maintained, that Spain has been materially injured by her colonies, it has been alleged, that by an immoderate extenſion of territory, the Spaniards have been led to the neglect of the territory, which they formerly poſſeſſed. But although Spain, and alſo Portugal, may have ſeverely ſuffered in this reſpect, it is ſeldom, if ever, that, from the nature of colonial power, any ſuch conſequences can ariſe to the mother-country from the poſſeſſion of the moſt widely ſpread colonial dominions. In the caſe of Spain eſpecially, whatever neglect there may have been in the management both of the mother-country and the colonies, the mal-adminiſtration of both thoſe parts of the empire muſt evidently have ariſen from other cauſes beſides their being united under one crown. Farther, the vaſt outlet to population which the Spaniſh colonies afford has been thought by many to be detrimental to the mother-country. They allege that the population of Spain has been drained by the demands and temptations for men which the colonies afford. Our author ſuggeſts a variety of conſiderations that tend to invalidate this objection. The indolent and adventurous, the nobles and ſoldiers of fortune, and men of conſiderable property, were the principal emigrants at the firſt ſettlement of the Spaniſh colonies in America; as conqueſt or plunder, and mining in ſearch of the precious metals were the only modes in which wealth was then ſought. Beſides, the drain of emigration has been chiefly confined to the population of the maritime provinces of Spain; and the whole amount of the emigration, at different periods, cannot be eſtimated very high. It has been ſaid that the rage for emigration to America was ſo much abated in a ſhort time after the diſcovery, chiefly by the ruin of many who flocked thither, that in the year 1550, there were not above 15 thouſand Spaniards in all the New World. From other documents it has been inferred, that the whole amount of thoſe who have emigrated to the Spaniſh colonies, during a period of three centuries, does not exceed 500,000. The drain of the Spaniſh population muſt therefore be wholly inadequate to account for the decline of the Spaniſh reſources, and the ſlow progreſs of the Spaniſh population. It is no leſs chimerical to imagine that the capital which has been drawn to the colonial agriculture and mining, can have impoveriſhed the mother-country in any conſiderable degree, than to ſuppoſe that the colonial emigration can have drained her population: and it is, therefore, to cauſes different from the emigration of inhabitants, and of capitals, that we muſt aſcribe the depopulation, the indolence, and the poverty of Spain. In order to account for the depopulation of Spain we may recur to the ravages of the plague, which, during three years in the middle of the 14th century, carried off two-thirds of the whole population of the peninſula, and which about three centuries afterwards, deſtroyed 200,000 perſons in the ſouthern provinces;—to the deſtruction occaſioned by dearth and famine;—to the cruel and inſane policy of Ferdinand, who, as an expreſſion of gratitude to God for the ſucceſſes of his arms, expelled from his dominions the whole tribe of Iſrael;—to the ſtill more bloody and impolitic meaſures of his ſucceſſor, who, about a century afterwards, drove out all the Mooriſh race;—and to the conſtant perſecutions and rebellions of theſe two claſſes during the interval between the great and general expulſions, which produced the effect of ſuddenly eradicating from the kingdom all the induſtry and ſkill which had raiſed it to ſuch a pitch of opulence and glory. The number of the Jews, who, in the year 1492, were butchered or driven out, is reckoned by ſome authors at 800,000 perſons, by others at 800,000 families; and the number of the Moors driven away by the edict of 1609, cannot be computed at leſs than a million. The beſt informed writers ſtate the loſs to the country at theſe two periods, and intervening intervals, to have amounted to between two and three millions; conſiſting of the moſt uſeful and valuable part of the community. We might enumerate other cauſes of the decline of Spain, ariſing from reſtrictions and impoſts, and a miſerable ſyſtem of law and police, both at home and in the colonies, which operated much more fatally than the acquiſition of colonial dominions, and which, indeed, counteracted any benefit they might otherwiſe have afforded. It is ſurely a proof, ſays Mr. B., that the downfal of a country was not cauſed by its colonial poſſeſſions, but by ſome evil in the national policy common to all its branches, when we find that the æra of adverſity was common to both the contiguous and remote provinces, and that the ſame circumſtances which raiſed up the colonies, and increaſed their beneficial effects upon the wealth of the parent ſtate, have elevated the parent ſtate alſo, reſcued her from inactive obſcurity, and placed her in the career of general improvement, in which her neighbours are engaged in both quarters of the globe.

The Portugueſe, incited by a ſpirit of diſcovery, and by a view to the great profits accruing to the Venetians from their commerce, during the 14th and 15th centuries, made ſeveral attempts, in the courſe of the 15th century, to find out a way by ſea to the countries from which the Moors brought them ivory and gold duſt acroſs the deſart. In proceſs of time they diſcovered the Madeiras, the Canaries, the Azores, the Cape de Verd iſlands, the coaſt of Guinea, that of Loango, Congo, Angola, and the Cape of Good Hope. They alſo extended their views to the Eaſt Indies, and afterwards to America. During the 16th century, the empire of Portugal was more extenſive than any over which the dominion of other ſtates has ever prevailed; and the territories that compoſed it, though almoſt all held by the right of recent diſcovery and conqueſt, were not, like thoſe of Spain and Ruſſia, ſubdued and retained with eaſe; nor were they tracts of uſeleſs country, thinly peopled, poſſeſſed only of unimproved natural reſources, and inhabited by a few tribes of wandering ſavages mingled here and there with nations ſomewhat more civilized. The Portugueſe conqueſts were gained with difficulty from nations far advanced in refinement and capable of reſiſtance; the extenſion of their territory obtained from right of diſcovery, that is, ſeized from leſs civilized nations, was equal to the moſt opulent of the dominions poſſeſſed by Spain, and poſſeſſed by tribes much more warlike than the Mexicans or Peruvians; and the length of ſea-coaſt, with various convenient ports, which bounded the eaſtern dominions of Portugal during this brilliant period, was ſufficient to inſure the moſt important commercial advantages from their intercourſe with the metropolis. The whole weſtern coaſt of Africa, with the greater part of the eaſt coaſt and the Cape of Good Hope, was ſubject to the dominion of the Portugueſe, and occupied at favourable intervals by their garriſons and factories. They alſo poſſeſſed the whole ſouthern coaſt of Aſia, together with as many of the Indian iſlands as they choſe to ſettle in, from the gulf of Perſia to China and Japan, where they had a few important commercial ſtations. This unparaleled extent of naval territory gave them the undiſputed command of all thoſe ſeas, and enabled them to carry into execution the ordinary ſchemes of the mercantile ſyſtem with uncommon vigour and ſucceſs, by confining all intercourſe with Aſia and Africa to their own European territories. The power, adds the writer whom we are now citing, which they poſſeſſed over the interior of thoſe vaſt and opulent regions, ſupported their commercial eſtabliſhments, and enabled them to gratify with unexampled licence that tyrannical ſpirit which has always, though in different degrees, ſignalized the intercourſe of European ſtates with the refined and amiable inhabitants of their Oriental provinces. Such, during the whole of the 16th, and the greateſt part of the 17th century, was the magnificent outline of the Portugueſe empire in Africa and Aſia. The romantic deſcriptions of their own authors, corroborated by the teſtimony of other nations, their rivals and enemies, are ſufficient to prove that the achievements and wealth of their nation in the provinces of the Eaſtern empire were ſuperior to any which it could boaſt of elſewhere; and the remains of the Portugueſe dominions in Africa, where at this day 15 kings are tributary to the court of Liſbon, together with the glittering fragments of the Aſiatic empire, corrupted by bad policy, as well as diſmembered by foreign conqueſt, may convince us of the important relations which the provincial wealth and power of this nation muſt have formerly borne to its whole reſources. The Eaſt Indian poſſeſſions of Portugal, during the 16th century, threw into their hands the whole commerce of Aſia, which, long before the diſcovery of the paſſage by the Cape of Good Hope, had formed one of the greateſt trades carried on between any two parts of the world; had enriched and refined the whole European empire of Rome, and raiſed the inconſiderable republic of Venice to a degree of power formidable to all the great nations of the continent. The ſame commerce, divided among ſeveral ſtates, has, ſince the downfal of the Portugueſe dominions, ſenſibly enriched all thoſe nations, and continues to form a very great part of their extended trade. We may judge, in ſome degree, of the extent of the trade carried on by the Portugueſe in their Aſiatic ſettlements, ſome time after their eaſtern empire had begun to decline from the competition of the Engliſh and Dutch, by a ſingle fact. In the year 1611, the Engliſh company's ſervants, in one of their voyages to Surat, ſaw a ſingle Portugueſe merchant fleet, conſiſting of 240 ſail, bound for one place, and deſtined only for the commerce of the northern and moſt trifling ſettlements. (Anderſon's Hiſt. of Commerce, ii. 245, 263.) The African and Aſiatic provinces, however, muſt be conſidered as conquered territories, held in ſubjugation by a few troops and ſquadrons of ſhips; not as colonies peopled by emigrants from the mother country, or by a race in which thoſe emigrants and their deſcendants bore a conſiderable proportion. Of theſe vaſt dominions the Portugueſe were nominal poſſeſſors; the treaſure and blood of the metropolis were waſted in wars with the native powers, and the relations of commerce were on every occaſion poſtponed for thoſe of conqueſt and dominion. Theſe circumſtances have eventually proved fatal to the Portugueſe dominion in the Eaſt, which has at length been transferred to other powers of ſuperior policy and ſtrength.

The Portugueſe trade with India, though rigorouſly confined to the ſubjects of the mother country, was never put into the hands of an excluſive company, incorporated by charter, except for a ſhort time, about the year 1731, when the experiment was unſucceſsfully tried. The ſovereign granted, from time to time, privileges of fitting out veſſels, under limitations, to private co-partners and individuals, who thus enjoyed a monopoly of the ſupplies required both by the Aſiatic and European provinces. The monopoly had been generally veſted in the crown, until the year 1752, when it was ſaid to be aboliſhed; but ſeveral important articles ſtill continued ſubject to the royal privileges, and could only be bought in India and ſold in Europe on the king's account. From the ſplendid pre-eminence which the Portugueſe trade with India once poſſeſſed, it has ſunk to a few annual voyages, in conſequence of the reduction of the Portugueſe empire in the Eaſt, and the bad management of the trade and ſettlements that ſtill remain. With a view to its revival, new excluſive grants have been made to mercantile adventurers in Europe, and an excluſive company has been eſtabliſhed at Goa (the chief Eaſt Indian ſettlement) for the management of the whole trade with China. Theſe abſurd managements have taken place ſince the year 1752, when the evils perceived to ariſe from monopolizing policy, induced the ſovereign to abandon ſeveral of his excluſive rights, and to pretend that the Eaſt Indian commerce was thrown open. While the Portugueſe conqueſts were rapidly ſurviving each other in the Eaſt, the diſcovery of Bengal, opened a new field of exertion in the Weſt. Brazil, however, compared with Aſiatic conqueſts, was regarded with indifference, and ſlowly peopled by malefactors, and by thoſe whom the perſecuting ſpirit of the times drove, from the mother-country. Among the emigrants of this period, ſacrificed to the cruel bigotry of the inquiſition, was a great body of Jews, who carried over with them to the colony the ſkill and induſtry with which they had enriched and ſtrengthened the European dominions of Portugal. Under their cultivation the natural wealth of this fruitful territory began to appear, and by degrees to attract the attention of government. All the Portugueſe ſubjects, who choſe to ſettle in Brazil, were permitted to ſubdue large tracks of country, and to hold them as fiefs of the crown, with abſolute power over the natives whom they had conquered, and with all the prerogatives of royalty, except capital juriſdiction, coinage, and tithes, which were invariably reſerved to the ſovereign. Theſe great territorial lords thus acquired an almoſt abſolute authority, over domains often extending 40 or 50 leagues along the ſea-coaſt; and generally leaſed out parts of their poſſeſſions to ſub-vaſſals for terms of 2 or 3 lives. This arrangement immediately attracted to the colony a number of adventurers and opulent perſons from the mother country. The importance of this colony, in conſequence of the whole territory of Brazil, and the cultivation of various uſeful articles, gradually increaſed; and its traffic with the parent ſtate, would have proved a great mutual benefit; if an erroneous policy had not confined it to a few ports in each part of the empire. Annual fleets from Liſbon and Oporto alone were permitted to carry on this rich commerce, under regulations ſimilar to thoſe of the Spaniſh flotas and galleons. Four emporiums, *viz.* Olinda, St. Salvador, Paraiba, and Rio Janeiro, were appointed for the deſtination of thoſe ſquadrons, and the ſupply of the whole colony. The 18th century opened with a diſcovery of gold and diamond mines; and ſince that period many regulations have been adopted, which have proved pernicious both to the colonies and to the parent ſtate. Companies were eſtabliſhed at Peru, Fernambuco, and Maragnan, which did not long ſurvive the downfal of Pombal, the Portugueſe miniſter: theſe have ceaſed to exiſt above 20 years, after proving highly injurious to both the mother-country and the colony during an equal period of time. A new and more liberal ſyſtem has been introduced; but the royal monopolies ſtill exiſt in their full force, and obſtruct the growth, as well as the circulation, of the moſt valuable ſtaple produce which Brazil ſupplies. Since Portugal has experienced the irretrievable loſs of her rich Eaſt Indian commerce, and a diminution of the traffic formerly carried on with Africa, Brazil is of great importance to her. This colony is better governed and peopled than any of the Spaniſh dominions; its proximity to Africa and connection with the Portugueſe ſettlements there, afford great facility in the increaſe of its cultivation, by means of negroes; the poſſeſſions of Brazil gives Portugal conſiderable weight in the continental politics; and the poſſeſſion of this noble colony, beſides yielding a clear revenue to the mother-country (above one-fourth of the whole national income) is the ſource of a great proportion of her whole commerce;—the imports from them being nearly equal to the whole imports from the other countries of Europe.

The colonies of Sweden and Denmark, are too inſignificant to influence, in any conſiderable degree, the proſperity of the parent ſtates, and bear a leſs proportion to the whole imperial reſources than thoſe of any other nation. The excluſive companies, which for a long ſeries of years monopolized all the colonial trade of both theſe countries, have been peculiarly injurious. See Company, *Daniſh* and *Swediſh*.

For an account of the colonies of France and England, the limits of our article oblige us to refer to the articles FRANCE and ENGLAND, WEST INDIES, EAST INDIES, and COMPANY, and the ſeveral individual iſlands of the Weſt Indies.

There are ſome other kinds of colonies, beſides thoſe above enumerated, of which we ſhall give a brief account. Conquered ſubjects or priſoners of war have been ſometimes removed to particular and ſelect places, either for ſafe cuſtody, or for the cultivation of waſte lands. The ancients more frequently practiſed this ſpecies of colonization than the moderns, who prefer exchanging the priſoners on each ſide. The Romans, in particular, were conſtantly accuſtomed to remove the more active and daring nations to a diſtance from their native abodes, and to oblige them to reſide in ſome ſelect place which was probably leſs defenſible than their own country, and where, of courſe, they would be more under command. We are not, however, without ſome examples of this kind, even in our own times. The Maroons, or remnant of the Spaniſh ſlaves, who had been relinquiſhed by their maſters, and left on the iſland of Jamaica, when the Spaniards were expelled by the Engliſh, after having long gallantly reſiſted the forces brought againſt them, at laſt ſubmitted to one of his majeſty's officers, upon condition of not being ſent off the iſland. To this ſubmiſſion they were induced by the fear of a new ſpecies of warfare with which they were threatened, *viz.* the uſe of blood-hounds to diſcover their retreats. But the legiſlative aſſembly of the iſland not only refuſed to pay the Spaniſh police-runners their ſtipulated bounty, but alſo took advantage of ſome unavoidable delays in the performance of the treaty to annul it altogether, and to tranſport the Maroons to Nova Scotia, whence they were afterwards removed to Sierra Leone. On account of this flagrant act of injuſtice the commanding officer of his majeſty's troops indignantly refuſed a handſome ſword, which the aſſembly offered him for his ſervices in putting an end to a war which had been ſo long protracted. See MAROONS.

Another kind of colonization is the removal of convicted criminals, or of debtors, to ſome deſart ſpot, in order to work the mines, or break up the land, and thus prepare it for more reſpectable coloniſts. The Ruſſians uſe this mode of colonizing their vaſt lands in Siberia. But the moſt intereſting colony of this deſcription, particularly to Engliſhmen, is that of NEW HOLLAND, which ſee.—Alſo, BOTANY-*bay*, and *New South* WALES.

Great ſums of money have been, and ſtill are, annually expended on this colony, but it has hitherto languiſhed; partly from the diſproportionate nnmber of the ſexes, and the idle habits of the convicts, but ſtill more from ſome radical defects in its adminiſtration, many parts of which render it more like a mere job for contractors and agents, than a well regulated ſyſtem for the gradual reformation of the criminals, and for rendering them uſeful ſubjects in future. The diſſentions alſo which have taken place among the officers there, cannot but have tended to injure the colony. Theſe diſſentions ſeem to have originated in ſome meaſure from the governor being always a naval officer. The abſurdity, for ſuch we muſt eſteem it, of a naval officer commanding in chief on ſhore, merely becauſe he went to the place by ſea, is fully equalled by ſeveral others, which demonſtrate how inadequate to the undertaking were the framers of the ſyſtem by which the colony is regulated.

During the firſt ten years, *viz.* from 1787 to 1797 incluſive, the number of convicts ſent to New South Wales was 5765 men and women, and 93 children, being in all 5858 perſons. The expence of tranſporting, feeding, and governing them, during that period, amounted to 1,087,230*l.* being above 177*l.* for each, excluſive of the expences previous to their embarkation.

The number of convicts remaining was as follows:

Men convicts in the ſettlement -	2175
Women - - - - -	939
Convicts ſent out in 1796 and 1797, Not arrived - -	695
Total -	3802

So that a loſs of 2049 convicts had been ſuſtained in this ſhort period; an evident proof of the moſt glaring miſmanagement. On the firſt of September, 1796, the agricultural ſtate of the colony was as follows:

	On account of government.	In poſſeſſion of private perſons.
Acres of land in cultivation -	1700	3719
Horſes - - -	14	43
Black cattle - -	150	77
Sheep - - -	191	1340
Goats - - -	111	1316
Swine - - -	59	1810

The later accounts which have been received are equally unpromiſing. The ſpirit of diſſention has increaſed, and ſpread itſelf to every rank: ſo alſo has the depravity of the convicts, in conſequence of their not being ſeparated, and placed under the controul of ſteady perſons who have an intereſt in watching over their moral improvement. Indeed, the viciouſneſs of the convicts increaſed by fellowſhip, and even many of the free ſettlers have, from the force of evil example, acquired the ſame bad habits. The quantity of land cultivated on the public account is too great, and the numerous public works abſorb the labour of the convicts, and leave but few of them to be hired out to ſettlers. Theſe circumſtances, together with the ill ſelection of the convicts, and of the ſettlers, as to their former employments, contribute to the want of ſucceſs in the colony.

It certainly is not improper to ſend, as matter of favour, criminals to remote and deſart places to procure their own livelihood, furniſhing them at firſt with a few neceſſaries, and then leaving them to their own induſtry, or to ſupply the free ſettlers in thoſe places with convicts for ſervants, in order to free them from the heavy expence incident to their procuring ſervants from a diſtance. But the idea of tranſporting large bodies of criminals to an immenſe diſtance, and employing them, under a ſtrong guard, in public works, where few ſuch works can poſſibly be wanted, and in cultivating land in the produce of which they have no intereſt, does not ſeem to have been happily choſen, or very promiſing, even in theory; and we may add, that practice, upon a very extenſive ſcale, has completely ſhewn its futility.

The Romans, it is true, tranſplanted their priſoners of war to diſtant countries, and employed them on public works; but theſe works were carried on in well inhabited countries, and were deſigned for the facilitation of the intercourſe between the ſeveral parts of the empire, or for adorning the cities with marks of the Roman grandeur.

We believe, however, that the colony of New South Wales might be made to anſwer much better, if a few ſimple regulations were adopted, and particularly if the employment of ſo many convicts on account of government was aboliſhed, and the convicts left more to their own induſtry.

It was formerly obſerved in Virginia, that the colony languiſhed ſo long as the cultivation of the ground, &c. was carried on as a public concern, but that it immediately begun to flouriſh when the lands were divided, and every one left to ſhift for himſelf.

The want of capital and experience among the majority of the convicts, forms no objection; as, by furniſhing thoſe accuſtomed to huſbandry, gardening, or uſeful trades, with the neceſſary ſeeds and tools, and "a very ſparing allowance of proviſions, to be gradually diminiſhed," there can be no doubt but that, in a very ſhort time, they would not only be able to repay the advances made them, with intereſt, but alſo to pay a gradually increaſing rent. As to thoſe bred to no profeſſion uſeful in the colony, they might be lett out by auction, for a year at a time, until they had acquired ſufficient experience: and a fourth part of their wages might be deducted and laid by, to form a ſtock when they were capable of uſing it, another part being paid into ſome benefit ſociety.

Hitherto we have ſpoken of external colonies, or thoſe in which the coloniſts recede from their mother-country, and eſtabliſh themſelves in foreign land, without, however, ſubmitting to their form of government.

It now remains to treat of thoſe colonies in which large communities of foreigners are, for ſome particular reaſons, permitted to enter and ſettle in a country; which colonies differ from thoſe founded by private adventurers, only becauſe they do not ſo ſtrongly affect the political ſyſtem of the country.

The Ruſſian government, having immenſe tracks of waſte lands, ſome of which are advantageouſly ſituated for mines or for commerce, has, as we have already ſaid, beſtowed great attention in endeavouring to people theſe tracks, as well by foreigners as by natives. The Pruſſian government has alſo beſtowed the ſame laudable attention to the improvement of the waſte lands in its poſſeſſion; and it even went ſo far as to require from the Poles a tribute of marriageable virgins, with a ſtipulated portion for each.

To this ſpecies of colony belongs what is uſually called the Babyloniſh captivity of the Jewiſh nation, and which is erroneouſly ſuppoſed to have been a removal of the whole nation in a ſtate of ſlavery: whereas it evidently appears, from their own records, that it ſimply meant the reſidence of the Jewiſh chiefs, and of their prieſts, at the court of the king of Babylon. The number of perſons carried off by the king himſelf, was (2 Kings, xxiv.) only 10,000; a number ſurely applicable only to the higher claſſes. The offices which many of them held in the Babylonian court, and ſubſequently in the Perſian, are a proof, that although they were, for obvious political reaſons, required to reſide at court, their ſituation there was perfectly honourable. It is probable, however, that their removal might occaſion the gradual emigration of a number of other families, who followed them for the ſake of employment, and ſpread over the Babylonian dominions; as their number was found to be greatly encreaſed, when they were allowed by the Perſians to return. They then amounted (Nehemiah, vii. Ezra, iii.) to 49,697 perſons.

Many other inſtances may be found, both in ancient and modern hiſtory, of this importation of people. The conquered Greeks filled the capital of the Roman empire, and, by the verſatility of their talents, acquired the ſame influence over the maſters of the world, as the modern French (who frequently boaſt of their Greek origin) have over the faſhionable part of our own country. By means of this influence, they introduced among the Romans all the vices for which they were notorious; and to the baneful effect of their influence, we may juſtly attribute, in great meaſure, the downfal of the empire, ſince they introduced a love of diſſipation, and of ſhowy, but trifling acquiſitions, inſtead of the more ſolid attainments which were required, before they contaminated the public mind.

The importation of ſlaves into a country, may be regarded as a kind of internal colony of the moſt important, becauſe dangerous nature. When the ſlaves are numerous, they are not only retained in ſubjection with difficulty, (being in general far ſuperior in bodily ſtrength) but they are alſo of very doubtful fidelity, and ever ready to join any invader, or to flock to the ſtandard of any military adventurer. There is yet ſtill greater danger if an independent ſtate exiſts in the neighbourhood, and particularly if it ſhould conſiſt of revolted ſlaves (as has lately happened in St. Domingo), becauſe the greater energy of an independent government enables it to proſecute any ambitious deſigns of conqueſt with decided advantage over a delegated authority.

It is, therefore, highly impolitic that ſlavery ſhould be conſtantly permitted in any country; and, although, for the ſake of bringing labourers to any particular ſpot, it it may be tolerated at firſt, it is the bounden duty of every ſtate to take deciſive meaſures to convert the ſlaves, by degrees, into free ſubjects, and to put a ſtop to the importation, as ſoon as the colony has obtained a certain population, and further to take ſome ſteps in order to liberate the ſlaves already imported, or at leaſt to make their offspring free at a certain age. Thus it will be requiſite for the coloniſt to attend to the welfare of his preſent ſtock, and to introduce taſk-work, whereby he will be changed, in time, from a commercial capitaliſt, or a needy planter, into a landed gentleman. He will then be ſolicitous only for his rents, and deprecate the idea of keeping more land in hand than is neceſſary for the ſupport of his eſtabliſhment, or to ſerve as an example of perfect cultivation and grazing to his tenants, to the moſt induſtrious of whom he might furniſh capital and favourable leaſes, in order to enable them to improve his own land.

To a neglect of this ſalutary precaution, we may attribute the preſent dangerous ſtate of the Dutch and Engliſh colonies in the Weſt Indies, ſince, notwithſtanding the length of time that they have been eſtabliſhed, the ſtate of ſociety in them is as crude and ſemi-barbarous as it was at the time of their being firſt ſettled.

It was probably owing to a ſimilar neglect that the weſtern provinces of the Roman empire were ſo ſpeedily ſubdued by the northern adventurers. The Roman provincials, like the planters in the Weſt Indies, ſeem to have had little repugnance to a change of maſters; partly becauſe the reſident planters were thus relieved, at leaſt for ſome time, from the claims of their creditors; partly becauſe the agents were enabled, in many caſes, to convert the plantations to their own benefit; and, laſtly, becauſe both were equally afraid that, in caſe the war was protracted, they ſhould loſe their ſlaves. See SLAVES.

As to their intrinſic nature, colonies are either *agricultural*, which grow within themſelves the principal articles of their food and ſubſiſtence; or they are *commercial*, which depend upon other countries for the neceſſaries of life, and devote themſelves to the traffic of a few ſtaple commodities. The northern ſtates of America and the Bermuda iſlands are ſo many inſtances of agricultural colonies; while the Weſt Indian iſlands, together with Virginia and Maryland on the continent, are examples of commercial colonies.

In reſpect to the advantages or diſadvantages of external dependent colonies, no perſon has more thoroughly conſidered the ſubject than Mr. Brougham, in his elaborate treatiſe "On the Colonial Policy of the European Powers." The adoption of all the poſitions advanced by that ingenious writer, may indeed be ſomewhat hazardous; eſpecially if we conſider the great degree of doubt and uncertainty which hangs over all political ſpeculations, on account of the difficulty, and ſtill more the danger of making experiments on thoſe ſubjects; to ſay nothing of the want of means for aſcertaining whether the effects are aſcribed to the right cauſes, when (as is uſual in human affairs) ſo many cauſes concur in producing thoſe effects.

The firſt advantage ariſing from colonies dependent upon any country, is the extenſion of the home trade; for ſuch in fact the trade between the mother-country and the colony may fairly be conſidered, becauſe the whole of the profits is retained within the ſtate; whereas in foreign trades, one of the profits, either that of the buying, or of the ſelling merchant, goes to enrich a foreign ſtate. The trade of a colony alſo produces a conſiderable augmentation of the mercantile navy of the mother-country, and, at the ſame time; as the ſhips and their crews are conſtantly retained within the power of the ſtate, there is far leſs danger of the ſailors being enticed into foreign ſervice, than if part of their time was ſpent in foreign ports. The European nations have anxiouſly endeavoured to confine the trade of their colonies to the merchants of the mother-country by poſitive regulations; but Mr. Brougham thinks this ſolicitude is abſurd and even nugatory. Merchants will, in all countries, prefer dealing with their own countrymen, with whoſe language, laws, and habits of thinking they are acquainted. And this is more eſpecially the caſe in commercial colonies, as they require in general ſuch large advances of capital, that few perſons would be inclined to inveſt ſums upon private foreign ſecurity.

But the greateſt utility of colonies, is the affording an opening for the employment of the ſuperfluous population of the mother-country, which muſt otherwiſe either emigrate to the neighbouring foreign nations, or die of want at home. The inhabitants, indeed, of agricultural colonies, are in general ſtationary, and, as it were, loſt to the mother-country; but theſe colonies only attract thoſe who cannot get employment at home, or in the commercial colonies, or thoſe who are in ſuch deſperate circumſtances that they are obliged to fly from home to avoid the importunities of their creditors. Commercial colonies, on the other hand, have for the moſt part only a temporary population, as the coloniſts, after ſpending a part of their time in the colony, generally return home with their fortunes improved, and carry with them, to the mother-country, the ſame ſpirit of improvement to which they owed their ſucceſs in the colony.

Commercial colonies have a further advantage, in furniſhing employment for thoſe large capitals which would otherwiſe be employed upon the more diſtant foreign trades, or lent to foreign ſtates.

We ſhall now ſay a few words reſpecting the diſadvantages ariſing from the poſſeſſion of colonies; theſe are ſo great that the economiſts have loudly declaimed againſt the utility of forming ſuch eſtabliſhments; but they have committed a fundamental error, in conſidering colonies as foreign ſtates. They ought rather to be conſidered as mere extenſions of the parent ſtate, into regions adapted to the production of articles which cannot be raiſed at home. A circulation of inhabitants is kept up by the commercial intercourſe between the colony and the mother-country, and alſo by the weakneſs incident to parts remote from the ſeat of government. So that, as the colonies require, at all times, the foſtering care of the mother-country, they are generally filled with the troops of the parent ſtate and their followers, and the ports are conſtantly reſorted to by its ſhipping, both mercantile and warlike. It were needleſs to inſiſt upon the powerful attractions reſulting from their common origin, their identity of language, and their ſimilarity of habits in thinking; as the effect of theſe, in producing a good underſtanding among nations, muſt ſtrike the moſt inattentive obſerver.

One of the principal diſadvantages of colonies, is the wars into which they ſeem to draw the nations which poſſeſs them. But although it is certainly true that external commercial colonies do, in the preſent times, generally become the ſeat of warfare between ſuch of the belligerent powers as poſſeſs them, it cannot be allowed that they are the cauſes of the war; for as they increaſe the frontier to be defended, thoſe nations which poſſeſs them will be leſs ready to engage in hoſtilities; and it is the weakneſs of the colonies, (on account of their deficient population preventing the raiſing of regular troops in them), that is the principal cauſe of the enemy chuſing rather to invade them, than to force his entry into the parent ſtate. The want of a powerful landed intereſt, in colonies of this nature, tends alſo to attract the hoſtilities of the enemy, as the poſſeſſion of them is ſeldom diſputed with the obſtinacy which marks the reſiſtance to invaſion in old ſettled countries; the defence being limited to the ſmall number of troops which the parent ſtate can ſpare without endangering her own ſafety, and whoſe exertions are impeded by the mixture of an ill-diſciplined militia, and of volunteers, unaccuſtomed to ſervice, and deploring their fate in being forced from their own homes.

This unfitneſs of external colonies, which are always underſtocked with inhabitants, to contribute ſupplies of men for the general defence of the ſtate, is uſually conſidered as a diſadvantage; but it cannot in reality be eſteemed to be one of much conſequence. Even in the parent ſtate itſelf, it is only in thoſe manufacturing diſtricts that produce articles, the demand for which is variable, that the recruiting ſervice meets with ſucceſs; in thoſe where agriculture prevails, or in which a ſtaple commodity is manufactured, that ſervice is in general unſucceſsful. It cannot, however, be of any conſequence, in regard to the general population of the empire, whether the mother-country ſupplies ſoldiers, or whether they are raiſed in the colony, and their place ſupplied by freſh ſettlers.

It is only the total want of ſyſtem, both in the planting and ſubſequent management of the Engliſh colonies, that rendered them at firſt, and ſtill keeps ſeveral of them expenſive burthens to the mother-country; as thoſe of other countries not only pay, in general, their own expences, but alſo furniſh a ſurplus revenue for the ſervice of the empire.

It will appear, from what we have already ſaid, that a great difference of political ſtrength ſubſiſts between agricultural and commercial colonies. The former are much ſtronger internally, and capable of affording, with their own reſources, a more obſtinate defence to the attacks of the enemy. But this ſtrength renders them refractory, and difficult to be controlled; hence they require either early reſtraint, and the obſervance of a ſtrict diſcipline, or they muſt be relinquiſhed as dependencies, and incorporated into the mother-country, as has recently been found neceſſary in reſpect to Ireland. On the other hand, although the weakneſs of commercial colonies renders them much more dependent on the ſtate to which they belong, yet, from the debts with which they are in general loaded, they are ever ready to ſubmit to any invader; eſpecially if the change can be made to a ſtate, where the merchants poſſeſs larger capitals than thoſe of the ſtate to which they have already been ſubjected; as this affords them a hope, not only of being releaſed for ſome time from the claims of their ancient creditors, but alſo gives them reaſon to ſuppoſe they may be able to procure ſtill greater credit from their new maſters. Every perſon acquainted with Weſt Indian affairs muſt acknowledge the truth of this remark; and with reſpect to other parts, we have, ourſelves, twice experienced the facility and even eagerneſs with which the Cape of Good Hope was ſurrendered to us.

The want of mercantile capital which our enemies in the Weſt Indies do not as yet poſſeſs, is the principal ſecurity we have that thoſe coloniſts will rather chuſe to remain under our dominion than fall into the hands of other powers, as they would, in that caſe, be obliged to diminiſh their cultivation in conſequence of the diminution in the advances made by the merchants upon their future crop. And as to any attempts at independence, the mother-country has a conſiderable ſecurity in the precarious ſituation of the inhabitants; in conſequence of the number of their ſlaves and the diſcontent that generally prevails among them. This latter circumſtance, might, by thoſe who think the poſſeſſion of colonies, and the monopoly of their trade, are of great benefit to a nation, be thought to afford a good argument againſt the abolition of the ſlave trade, as tending indirectly to leſſen the dependency of the colonies. But we may remark, that the greater ſtrength of the colonies, ariſing from their internal improvement in conſequence of the abolition of the ſlave trade, would more than counterbalance the danger of their revolt, as they would, in conſequence of ſuch ſtrength, run leſs hazard of falling into the hands of an enemy. And the event of the American war has fully proved, that even in the caſe of the colonies revolting, when they had acquired ſufficient ſtrength, the commercial intercourſe between the two countries would continue, and probably rapidly increaſe; ſo that the government would, at the worſt, loſe only an expenſive incumbrance. It can only be by the influx of foreigners, belonging to a mercantile nation, in ſuch numbers as to acquire a preponderance in the ſtate, ſo as to alter the fundamental laws and language of the colony, that any great change in its commercial relations would be effected.

The moſt ſerious diſadvantage of colonies, is that they divert the capital of the nation from the improvement of the mother-country; although this improvement is certainly the moſt advantageous employment in which the capital of any nation can be engaged. It has indeed been aſſerted, that the labour of one man on the continent of America, produced more to the ſtate than four at home; but this muſt be regarded as the mere rant of viſionary politicians, being totally unfounded and abſurd in the higheſt degree; for the ſubjects at home being directly taxed, muſt yield far more revenue than thoſe in the colonies, who are in general only indirectly taxed to the common ſervice of the empire, by the cuſtoms levied upon the commercial intercourſe of the two countries. The ſame perſons aſſerted that each white perſon in Virginia and Maryland, took off from ten to twelve pounds a year of the growth or manufactures of the mother-country. But the cuſtom-houſe books are ſufficient evidence that this calculation was much over-rated; for the exports to thoſe colonies were never more than 300,000*l.* a year, and therefore, allowing them to contain, as was ſtated, 120,000 white perſons, the conſumption of each perſon was only 1*l.* 13*s.* 4*d.* a head. The whole of the exports to America, when at the higheſt, was only about 834,000*l.* a year; and this tends to ſhow that it is better to retain the induſtry of the inhabitants of any country within its own ſphere, and encourage the cultivation of the waſte lands, than to divert it to diſtant colonization. It may, however, be ſometimes neceſſary, as a meaſure of precaution, to ſecure the poſſeſſion of diſtant places, when it is known, or ſuſpected, that the uſual enemies of the ſtate intend to colonize them; but it is extremely improvident to foſter theſe diſtant colonies at the expence of the mother-country, as is done in reſpect to the Britiſh colonies. When an old ſettled country is improved to the higheſt, then, and then only, can it be neceſſary to provide outlets for the employment of the ſurplus capital of its ſubjects, by conquering, or purchaſing ſome poor country, with a view to its improvement.

As to internal colonies, the encouragement of foreigners, and eſpecially the importation of foreign ſlaves, muſt, in general, be regarded as errors in politics. The procuring of a ſtock of labourers in the firſt ſtage of breaking up a new and uninhabited colony, the introduction of new manufactures, or of new commercial relations, can alone juſtify ſuch meaſures. And ſurely it is far better to endeavour to attain theſe ends by other means. The removal of idle and diſorderly perſons from great cities, the ſending out intelligent travellers into other countries, the encouragement of experimental philoſophers and chemiſts, together with the apprenticing of clever youths to merchants in foreign countries, would probably be equally efficacious. See Smith's Wealth of Nations, B. iv. chap. 7. Robertſon's Hiſt. of America, vol. iii. Brougham's Inquiry into the Colonial Policy of the European Powers, 1803, vol. i. and ii. paſſim. Paley's Principles of Moral and Political Philoſophy, vol. i. p. 381. Edwards's Weſt Indies, vol. ii.

Colony *of Bees.* See Hive.

COLOONY, in *Geography*, a ſmall poſt-town of the county of Sligo, Ireland, remarkable for the check given to the progreſs of the French troops under general Humbert, in September, 1798, by the gallantry of lieutenant-colonel Vereker with about 300 men chiefly of the city of Limerick militia. Though col. Vereker was obliged to retreat in conſequence of the number of the enemy, yet he ſaved the town of Sligo, and by the delay he occaſioned, enabled marquis Cornwallis to come up with and entirely ſubdue the French force. Coloony is 98 Iriſh miles N.W. from Dublin, and five S. from Sligo.

COLOOR, or Colore, a town of Hindooſtan, in the circar of Guntoor, which poſſeſſes a diamond mine on the ſouthern bank of the Kiſtnah, and not far from Condavir.

COLOPENA Regio, in *Ancient Geography*, a country of Aſia in Cappadocia; Sebaſtopolis and Sebaſte are towns of this country.

COLOPHON, a town of Aſia Minor now *Attoleſco*, or according to others, *Belvidere*. It was one of the chief cities of the Ionian league, ſeated near the ſea, and not, as Pliny calls it, an inland city, in the ſmall river Haleſus, N.W. of Epheſus and S.S.E of Smyrna. It was founded by Mopſus, grandſon of Tireſias, and, in proceſs of time, Damaſichthon and Promether, ſons of Codrus, conducted a colony hither. It was deſtroyed by Lyſimachus, and its inhabitants were ſent to people Epheſus; but after his death it was rebuilt in a more convenient ſituation. The Colophonians were ſuch excellent horſemen, that thoſe, for whom they declared themſelves, were ſure of victory; whence the trite proverb "Τον Κολοφωνα επεθηκε, colophonem addere," *i. e.* to put the laſt hand to a work, or ſucceſsfully to terminate it. Colophon was the birth-place of Nicander, and one of the ſeven cities that claimed Homer, who lived there ſome time, as Herodotus informs us. The ancients mention a famous grove and temple of Apollo Darius in the neighbourhood of this city; whence ſome have ſaid that he derived this appellation, though others ſay that he was ſo called from a mountain bearing that name. The ſmall town of "Notium," on the ſame coaſt, often mentioned by Livy, belonged to the Colophonians, and the Romans allowed it the ſame privileges, which they granted to Colophon itſelf. Pliny informs us, that they collected in the vicinity of Colophon, a reſin of a yellowiſh red colour, which being bruiſed, emitted a ſtrong odour; and hence ſome have derived the name of *Colyphony*, now frequently called "Spaniſh wax," or "Grecian reſin," as it is brought from one or the other of thoſe countries. Its epiſcopal ſee was ſubject to the metropolis of Epheſus.

Colophon, a town of Greece in Epirus.

COLOPHONIA, in *Botany*, Commers. See Bursera *paniculata*.

COLOPS, in *Geography*, the name given by Dion to a river of Pannonia, called *Colapis*, by Strabo.

COLOQUINTIDA, in the *Materia Medica*. See Colocynthis.

COLOR, in the *Ancient Muſic*. See Colours.

Color *Indicus*. See Indicus *Color*.

Color *nero e roſſo*, Ital. black and red, in *Muſic*. We have ſeen in Bene't college, Cambridge, old muſic books of Henry VII.'s time, in which ſome of the notes were black, and ſome red.

COLORADO, in *Geography*, a river of New Mexico, in the ſouth-weſtern part, which flows into the northern part of the Vermilion ſea, or gulf of California, called by D'Anville *colorado de los maityres*. The courſe of this river, which is generally from N E. to S.W. ſometimes W. may be computed at 600 Britiſh miles. It is called Rio Colorado, or Red river, becauſe the waters acquire that colour from the red clay on which the rains fall. Its ſtream is deep and copious, and capable of conſiderable navigation. The neighbouring ſavages, who ſwim acroſs it by a peculiar artifice, are denominated *cocomaricopas*, which ſee. This river is joined from the eaſt by a large river, called Gila, which, however, is everywhere fordable. The country between theſe rivers is ſaid to be an upland deſart, without water or paſture. On the other ſide of the Colorado, the country is ſaid, on the contrary, to be very fertile, and the natives rather fond of cultivation. It is thought that conſiderable rivers alſo join the Colorado from the weſt, flowing from the ſame chain of mountains that ſupply the ſources of the Rio Bravo, in lat. 40°. Among theſe the Zaguananas is the moſt lengthened ſtream, and may therefore be regarded as the Colorado itſelf. On the weſt of the Colorado, the river of Martyrs, and that of Pyramids, have umbraceous terminations, perhaps in the ſame lakes, or, perhaps in the Colorado. In lat. 39° W. long. from Madrid, 110° 30′, there is a large lake without a name, which receives two conſiderable rivers from the eaſt, one of which is called Buenara. From lat. 40° to 43°, and under the ſame meridian, extends another lake, which, though not fully explored, ſeems to be that of Imparices, where the fathers Velez and Eſcalante terminated their diſcoveries, and the utmoſt inland knowledge of the Spaniards. If, indeed, the Spaniards have explored that part of the country, they conceal their information.

On the eaſt of the ſame chain, from which ſprings the Rio Bravo, ariſe two rivers, which probably join the Miſſvari; and it appears that the eaſtern river of Colorado has been confounded with another river of the ſame name, with the epithet of Nachitos, which probably joins the Arkanza or Akanſas. See Colorado or *Riviere Rouge*, infra.

Colorado, a river of New Mexico, which runs into the bay of St. Bernard, in the gulf of Mexico.

Colorado, *Riviere Rouge*, or *Red River*, a river of North America, in Louiſiana, which runs into the gulf of Mexico, or rather joins the Miſſiſſippi river, before it falls into this gulf, ſome miles above New Orleans.

COLORADOS, Los, a numerous cluſter of ſmall iſlands or rocks, near the N.W. coaſt of the iſland of Cuba.

COLORATURA, in the *Italian Muſic*, is uſed to denote all ſorts of variations, trillos, diminutions, &c. that can render a ſong agreeable.

COLORBASIANS. See Colarbasians.

COLOREDO, in *Geography*, a town belonging to the ſtate of Venice, in the country of Friuli; ſeven miles N.W. of Udina.

COLORETTI, Matteo, in *Biography*, was born at Reggio, in the year 1611, and is ſpoken of by Tiraboſchi and the abbé Lanzi, as a moſt excellent painter of portraits.

COLORIFIC *earths*, in *Mineralogy*, a claſs or tribe of earths, in the arrangement of Kirwan, deſcribed by him as ſtrongly ſtaining the fingers. Of theſe he enumerates four families, *viz.* red, yellow, black, and green; the *red* is the reddle, or rubrica fabrilis. Rothel. Laſni, o. 973. Of dark cochineal red colour, or intermediate between brick and blood red, having neither luſtre nor tranſparency; fracture, earthy, ſometimes conchoidal; fragments, 1; hardneſs, 4; ſp. gr. inconſiderable; adhering pretty ſtrongly to the tongue; feeling rough; aſſuming a poliſh from the nail; ſtrongly ſtaining the fingers; falling immediately into powder in water, and not becoming ductile; not efferveſcing, nor eaſily diſſolving in acids. When heated to redneſs, crackling and growing black; at 159° the ſpecimen (Leſke, o. 973) melted into a dark greeniſh yellow frothy enamel. It differs from red ochres only by containing more argill. The red colour proceeds from oxygenation, and the abſence of acid. The mere air of water is expelled by heat, the browner it grows. The *yellow*, Gellebarde, Leſke. o. 1098, is of an ochre yellow colour; as to luſtre, externally it often hath ſome gloſs, but internally none; tranſparency, o; fracture earthy, often inclining to the conchoidal; fragments, o; hardneſs, 3; ſp. gr. inconſiderable; adheres ſtrongly to the tongue; feels ſmooth, or ſomewhat greaſy; takes a high poliſh from the nail; ſtrongly ſtains the fingers; in water it immediately falls to pieces with ſome hiſſing; and afterwards to powder, without diffuſing itſelf through it; does not efferveſce with acids, nor is eaſily ſoluble in them; heated to redneſs, it crackles, hardens, and acquires a red colour, and gives a reddiſh ſtreak. At 156°, Mr. Kirwan melted the ſpecimen, Leſke, (o.1098) into a liver-brown porous porcelain maſs. This yellow earth differs from ochres only in containing a greater proportion of argill; the yellow colour proceeds from the calx of iron, highly oxygenated, and probably containing both water and acid. Thoſe earths which contain a large proportion of iron, have rather an orange colour. According to the analyſis of M. Sage of Paris, who has the merit of preſerving to his countrymen the immenſe gains acquired by the Dutch from converting this yellow earth into what is there called "Engliſh red," it contains 50 per cent argill, 40 oxyd of iron, 10 of water, acidulated by vitriolic acid. Mem. Par. 1779, 313. The 3d family, or black, black chalk. Schwartze, Kreide, Zeichen, Schiifer, Leſke, 3.972; Pierre noire of Briſſon, p. 163, is of a greyiſh black colour; luſtre, o; tranſparency, o; fracture imperfectly curved ſlaty; fragments 1, partly flat, partly long ſplintery; hardneſs, 5; ſp. gr. 2,114. by Kirwan's trial by Briſſon, 2,186 before abſorption of, 2,277 after abſorption of water; adheres ſlightly to the tongue, feels ſmooth, aſſumes a poliſh from a knife; gives a black ſtreak, and marks black; in water does not readily moulder, but if taken out cracks in a ſhort time; does not effervefce with acids, nor eaſily diſſolve in them; heated to redneſs, it crackles and becomes reddiſh grey; and contains ſomewhat vitriolic. The 4th family, green earth. Leſke, 0.1013, is of a greyiſh green colour; found generally in lumps in the cavities of other ſtones, or externally inveſting them; luſtre, 0; tranſparency, 0; fracture, earthy, ſometimes uneven, ſometimes verging to the conchoidal; fragments, 2; hardneſs, from 6 to 7; ſp. gr. 2,637; ſometimes feels ſmooth, does not aſſume a poliſh from the knife, nor adhere to the tongue, nor ſtain the fingers, nor mark while dry, and when wet but lightly, in water it often crumbles after ſtanding about half an hour; does not effervefce with acids, nor is eaſily ſoluble in them; heated to redneſs, it crackles and becomes of a dark reddiſh cream colour; at 147°, the ſpecimen (Leſke, 0. 013) melted into a black compact glaſs, reſembling that of baſalt; which ſhews it to conſiſt of ſilex, argill, iron not much oxygenated, and oxyd of nickel, from which the green colour is derived, beſides water. Kirwan's Elem. of Mineralogy, [illegible]

COLORINA, or COLARINA, in *Ancient Geography*, a town of Arabia Felix. Ptolemy.

COLORISATION, or COLORATION, in *Pharmacy*, a term applied to the ſeveral changes of colour which bodies undergo in the various operations of nature, or art; as by fermentations, lotions, coctions, oxydations, &c.

COLORITES, in *Eccleſiaſtical Hiſtory*, a congregation of Auguſtin monks, inſtituted about 1530, and ſo called from *Colorito*, a mountain near Morano, in Calabria, where a church was erected to the Virgin Mary.

COLORNO, in *Geography*, a town of Italy, in the Parmeſan; 7 miles N. of Parma.

COLOS, a town of Tranſylvania; 4 miles N. of Coloſvar.

COLOSER SALT MINE, in Hungary; the ſtratum of rock ſalt in this famous mine, is of the enormous thickneſs of 60 fathoms; the diameter of the excavation made therein by the miners, is 50 fathoms. "Born's Hungary," p. 140, 143.

COLOSVAR. See COLOSVAR.

COLOSSAL COLUMN. See COLUMN.

COLOSSE, in *Ancient Geography*, now *Chonos*, or *Konos*, a city of Phrygia Major, in that part called Pacatian, ſeated on an eminence, on the ſouth ſide of the Meander. It was built by the river Lycus, near the place where, according to Herodotus (l. vii. c. 30.) it begins to run under ground, as it does for five furlongs before it riſes again, and flows into the Meander. This city was ſituated at an equal diſtance between Laodicea and Hierapolis, and to this place Xerxes came in his expedition againſt Greece. All theſe three cities periſhed by an earthquake, ſays Euſebius, in the 10th year of Nero, or about two years after St. Paul's epiſtle was ſent to the Chriſtians at Coloſſe. The government of this city was democratic, and its firſt magiſtrate bore the title of archon and prætor. This city, having been forcibly transferred to the Perſians by the Macedonians, paſſed afterwards to the Saleucidæ. After the defeat of Antiochus III. at the battle of Magneſia, it became ſubject to Eumenes, king of Pergamus. And when Attalus, the laſt of his ſucceſſors, bequeathed his dominions to the Romans, this city, with the whole of Phrygia, formed a part of the proconſular province of Aſia, which diviſion ſubſiſted till the time of Conſtantine. After the reign of this prince, Phrygia was divided into Phrygia Pacatiana, and Salutaris, and Coloſſe was the ſixth city of the firſt diviſion. It afterwards took the name of Chonos, or Konos.

COLOSSIANS, *Epiſtle to the*, in *Biblical Hiſtory*, a canonical epiſtle, addreſſed to the Chriſtians at Coloſſe by the apoſtle Paul, and conveyed to them by Tychicus and Oneſimus, towards the cloſe of St. Paul's firſt impriſonment at Rome, which was about the year of our Lord 63, or the 9th of the emperor Nero. As Timothy joins with the apoſtle in the ſalutation at the beginning of this epiſtle, he was ſtill at Rome, and not yet ſent away to Philippi; and hence Dr. Lardner concludes, that this epiſtle was written about the ſame time with that to the Philippians, in the year 62, and ſome time before the end of it. Although it appears from this epiſtle, that a Chriſtian church was eſtabliſhed at Coloſſe; we have no account by whom, or at what time, it was founded. Some have concluded from chap. ii. 1. that St. Paul had never been there himſelf. It is not, however, improbable, though no mention occurs of this fact in the hiſtory of the Acts, that the Coloſſians might have been converted while Paul reſided at Epheſus, conſidering more eſpecially that he ſpent no leſs than three years in that city, and preached with ſo much ſucceſs, that St. Luke tells us, (Acts, xix. 20.) that "all they who dwelt in Aſia heard the word of the Lord, both Jews and Greeks." (See Acts, ch. xvi. 6. xviii. 23.) Dr. Lardner, arguing from the teſtimony of Theodoret (tom. iii. p. 342, 343.), who lived in the 5th century, alleges a variety of conſiderations, inducing him to think, that the churches of Coloſſe and Laodicea, had been planted by St. Paul, and that the Chriſtians there were his converts. Of theſe we ſhall only ſelect the three following, *viz.* that the apoſtle was twice in Phrygia, in which were Coloſſe, Laodicea, and Hierapolis (Acts, xvi. 6.); that he does in effect, or even expreſsly ſay, that he had diſpenſed the goſpel to the Coloſſians (Epiſt. ch. i. 21—25.): and that from ſeveral paſſages which occur in this epiſtle, it appears, that the apoſtle is not writing to ſtrangers, but to acquaintance, diſciples, and converts.

The Chriſtians of the church at Coloſſe ſeem, from the honourable teſtimony that is born to them in this epiſtle, to have maintained an honourable character for their party, and the zeal they diſcovered for the goſpel; nevertheleſs, we find, from the cautions addreſſed to them in the ſecond chapter, that they were in ſome danger of being drawn aſide by the ſubtleties of the Heathen philoſophers, and the inſinuations of certain Jewiſh zealots, who inſiſted upon the neceſſity of conforming to the ceremonies of the Moſaic law. Accordingly, the grand deſign of this epiſtle is to excite the Coloſſians, by the moſt perſuaſive arguments, to a temper and behaviour worthy of their ſacred character, and to ſecure them from the influence of thoſe Pagan ſophiſts, or Jewiſh bigots, who would ſeduce them from the purity of the Chriſtian faith.

COLOSSUS, a ſtatue of enormous or gigantic ſize.

The moſt eminent of this kind was the coloſſus of Rhodes, one of the wonders of the world, a brazen ſtatue of Apollo, ſo high, that ſhips paſſed with full ſails betwixt its legs. It was the workmanſhip of Chares, a diſciple of Lyſippus; who ſpent twelve years in making it: it was at length overthrown by an earthquake, B. C. 224. after having ſtood about ſixty-ſix years. Its height was a hundred and five feet: there were few people who could encompaſs its thumb, which is ſaid to have been a fathom in circumference, and its fingers were larger than moſt ſtatues. It was hollow, and in its cavities were large ſtones employed by the artificer to counterbalance its weight, and render it ſteady on its pedeſtal.

On occaſion of the damage which the city of Rhodes ſuſtained by the above-mentioned earthquake, the inhabitants ſent ambaſſadors to all the princes and ſtates of Greek origin, in order to ſolicit aſſiſtance for repairing it; and they obtained large ſums, particularly from the kings of Egypt, Macedon, Syria, Pontus, and Bithynia, which amounted to a ſum five times exceeding the damages which they had ſuffered. But inſtead of ſetting up the coloſſus again, for which purpoſe the greateſt part of it was given, they pretended that the oracle of Delphos had forbidden it, and converted the money to other uſes. Accordingly the coloſſus lay neglected on the ground for the ſpace of 894 years, at the expiration of which period, or about the year of our Lord 653, or 672, Moawyas, the 6th caliph or emperor of the Saracens, made himſelf maſter of Rhodes, and afterwards ſold their ſtatue, reduced to fragments, to a Jewiſh merchant, who loaded 900 camels with the metal; ſo that, allowing 800 pounds weight for each load, the braſs of the coloſſus, after the diminution which it had ſuſtained by ruſt, and probably by theft, amounted to 720 thouſand pounds weight.

Some critics obſerve, that the coloſſus of Rhodes gave its own name to the people among whom it ſtood; and that many, at leaſt among the ancient poets, call the Rhodians *Coloſſians:* hence they advance an opinion, that the Coloſſians in ſcripture, to whom St. Paul directs his epiſtle, are, in reality, the inhabitants of Rhodes. Of this ſentiment are Suidas, Calepine, Munſter, &c.

The baſis that ſupported it was of a triangular figure: its extremities were ſuſtained by ſixty pillars of marble. There was a winding ſtair-caſe to go up to the top of it; from whence one might diſcover Syria, and the ſhips that went to Egypt, in a great looking-glaſs that was hung about the neck of the ſtatue. This enormous ſtatue was not the only one that attracted attention in the city of Rhodes. Pliny (l. xxxiv. c. 37.) reckons 100 other coloſſuſes not ſo large, which roſe majeſtically in its different quarters. Beſides theſe, here were to be ſeen five others, the work of Briaxis, and repreſenting divinities. Among the antiquities of Rome, there were ſeven famous coloſſuſes: two of Jupiter, as many of Apollo, one of Nero, one of Domitian, and one of the Sun.

COLOSTRUM, or Colostra, in *Medicine*, the firſt milk of any animal after bringing forth young, called in common *beaſtlings*.

It is remarkable that this milk is generally cathartic, and purges off the meconium; thus ſerving both as an aliment and medicine.

The ſame name is likewiſe given to a diſeaſe which this thick coagulated milk ſometimes occaſions.

An emulſion prepared with turpentine, diſſolved with the yolk of an egg, is ſometimes alſo called by that name.

COLOSVAR or Clausenburg, in *Geography*, the *Zeugma* of the ancients, by the Hungarians called *Koloſvar*, and in Latin *Claudiopolis*, a town of Tranſylvania, ſeated on the firſt branch of the river Samos, and ſurrounded by an ancient thick wall, where the ſtates of the province uſually aſſemble. The univerſity was ſuppreſſed in the year 1782. The Unitarians, who formed one of the ſects received in Tranſylvania, eſtabliſhed their principal ſeat in this place: 255 miles E.S.E. from Vienna, and 45 N.N.E. from Belgrade. N. lat. 46° 57′. E. long. 22° 21′.

COLOT, Germain, in *Biography*, a famous lithotomiſt, of the 15th century, practiſed ſurgery at Paris, during the reign of Lewis IX., from the year 1461 to 1480, and was in great favour with that prince. He was the firſt regular bred ſurgeon who practiſed lithotomy. The operation before his time had been engroſſed by perſons practiſing no other part of ſurgery. Regular practitioners had probably been deterred from interfering in the buſineſs, from reverence to the authority of Hippocrates, who obliged his diſciples to ſwear they would not perform the operation, "Nec vero calculo laborantes ſecabo." He ingratiated himſelf with ſome of the itinerant practitioners, ſaw them perform the operation, and began with cutting dead bodies. Having communicated his ideas to the phyſicians of the court, they obtained leave from Lewis, that he might operate on a condemned criminal, who was attacked with the ſtone in the bladder. The criminal conſented, on the condition promiſed, that he ſhould be pardoned the crime he had committed. The operation was ſucceſsfully performed, the patient recovering, it is ſaid, in fifteen days. Colot obtained great reputation by the cure, which was rewarded by a penſion from his ſovereign. The time of his death is not known. Eloy. Dict. Hiſt.

Colot, Laurence, a deſcendant of Germain, from whom he acquired the art of cutting for the ſtone, was in great reputation, in the early part, and to the middle of the 16th century, for his ſkill in performing the operation, by what is called the greater apparatus. By this method the urethra and neck of the bladder are neceſſarily cut through, which ſubjected the patients, not unfrequently, to fiſtula, and other inconveniences, yet by his dexterity in operating theſe accidents were often avoided, which gave him ſo much credit, that he was ſent for to viſit patients in Flanders, and other diſtant countries. To retain him in France, Henry II. made him his ſurgeon in ordinary in the year 1550, rewarding him with a penſion, adequate to the loſs he ſuſtained, by being prevented viſiting patients in foreign countries. He alſo created for him the poſt of lithotomiſt to the royal family, which was continued to three of his deſcendants. Philip, the laſt of them, died in 1656, aged ſixty-three years.

Colot, Francis, ſon of Philip, appears to have inherited, with the name, the ſkill and dexterity of his anceſtors, in performing the operation of lithotomy. He left a treatiſe on the operation, which was publiſhed in 1727, under the title of "Traite de l'Operation de la taille, avec des obſervations ſur la Formation de la Pierre, et les Suppreſſions d'Urine," 12mo. Paris. In this work he gives a ſhort hiſtory of the method of operating by the greater apparatus. It was invented, he ſays, by John de Romanis, a phyſician of Cremona, in Italy, in 1525, and by him communicated to Marianus Sanctus, who inſtructed Octavian de Villa, a ſurgeon at Rome. Marianus publiſhed, in 1535, "Libellus Aureus, de lapide e Veſica per inciſionem extrahendo," 8vo. Venet. Of Octavian de Ville, who was ſeveral times called to France, to perform the operation, Laurence Colot is ſuppoſed to have obtained ſome valuable information on the ſubject, which contributed much to the celebrity he afterwards enjoyed. The method of operating by the greater apparatus has been long ſince abandoned for a more ſimple and eaſy operation, therefore called, by the leſſer apparatus, firſt diſcovered, Mr. Sharp ſays, by Mr. Foubert, an ingenious French ſurgeon, but much improved by Mr. Cheſelden, in which the urethra and neck of the bladder are avoided by the operator: with Francis Colot, the celebrity of the family, ſeems to have been extinguiſhed. Eloy. Dict. Hiſt.

COLOUR, or Color, from the Latin, *color*, in *Philoſophy*, means that property of bodies which affects the ſight only; thus the graſs in the fields has a green colour, blood has a red colour, the ſky generally appears of a blue colour, and ſo forth; nor can thoſe colours be diſtinguiſhed by any of our other ſenſes, beſides the ſight. The variety of colours, as they are preſented to us by the ſubſtances that ſurround us, is immenſe, and from them ariſes the admirable beauty of the works of nature in the animal, in the vegetable, and in the mineral kingdom, or, more properly ſpeaking, in the univerſe. The ſcience, which examines and explains the various properties of the colours of light and of natural bodies, and which forms a principal branch of optics, has been properly denominated *chromatics*, from the Greek word, χρωμα, which ſignifies *colour*. We ſhall, however, ſtate this theory in the preſent article, as being much more obviouſly recurred to by thoſe perſons who wiſh to be informed on the ſubject. A diſtinct idea of what is meant by the word *light*, may be eaſily formed by its contraſt with darkneſs, which is a privation of light. With our eyes ſhut we have darkneſs; if we open our eyes, whatever we perceive through them is occaſioned by the agency of light, and the various colours of bodies are parts of that light.—It has ſometimes been pretended by certain ignorant perſons, that they could diſtinguiſh colours by the touch; but the teſtimony of divers intelligent perſons, who have had the misfortune of being blind, in conſequence of which their touch has, from neceſſity, become very exquiſite, has conſtantly contradicted thoſe vain aſſertions. Beſides, it will appear from the following theory of colours, that to diſcriminate colours by the touch is utterly impracticable. There are indeed certain pigments of common uſe in painting, which, either from their roughneſs, ſmoothneſs, unctuoſity, or other quality, may affect the touch, and with a little practice a perſon may learn to diſtinguiſh the feel of vermillion which looks red from that of ſap-green, which looks green, and ſo forth; but this is not the art of diſtinguiſhing colours by the touch. It is only the art of diſtinguiſhing certain peculiarities of ſurface. In fact if two pigments exactly of the ſame texture (and ſeveral ſuch there are) but of different colour, be preſented to the fingers of a man with his eyes ſhut, he will pronounce them to be exactly of the ſame colour.

The queſtions which naturally occur to the human mind in the contemplation of colours, are, whence do they derive their origin?—Are they produced by the coloured bodies themſelves, or by ſomething external?—Do they move from the coloured bodies to our eyes, and ſtrike upon them, or enter them; or are they owing to ſome medium interpoſed between the various bodies of the univerſe?—Are they material or not?

The ideas entertained by the ancients concerning the nature of colours, were moſtly wild and abſurd; nor has the preſent theory, imperfect as it is, been formed without an innumerable variety of experiments, obſervations, and the concurring inveſtigations of a great many ingenious perſons. The followers of Pythagoras called colour the ſuperficies of bodies; Plato conſidered it as a flame iſſuing from them; Zeno called it the firſt configuration of matter; and Ariſtotle ſaid it was that which rendered bodies actually tranſparent. We need not add a formal refutation of thoſe extravagant ideas, which were the mere offſpring of the imagination, unſupported by experience and by reaſon. The philoſophers of thoſe times paid little or no regard to experiments; hence they made no diſcoveries or improvements worthy of being recorded. A long and unprofitable period of nearly 2000 years elapſed, from the commencement of philoſophical ſtudies in Greece, until about the time of Deſcartes, when the revival of learning in Europe renewed with additional vigour the enquiries concerning the nature of light and colours. And it is curious to obſerve by what ſmall ſteps, and what circuitous ways, any uſeful diſcoveries were made. See Prieſtley's hiſtory of viſion, light, and colours. Deſcartes conſidered colour as a modification of light, and he attributed the difference of colour to the prevalence of the direct or rotatory direction of light. Grimaldi, Dechales, and others, ſuppoſed that a certain elaſtic medium of a peculiar kind filled the univerſe, and that the differences of colour depended upon the quick or ſlow vibrations of that medium. Rohault imagined that the different colours were produced by the rays of light entering the eye at different angles with reſpect to the optic axis. And Dr. Hook imagined that colour is cauſed by the ſenſation of the oblique or uneven pulſe of light; which being capable of no more than two varieties, he concluded there could be no more than two primary colours. Such were the ideas of philoſophers reſpecting the nature of colours, when Sir Iſaac Newton began to examine the ſubject in his cautious experimental manner, by which means, about the year 1666, he diſcovered the foundation of a theory of colours, which has been juſtly adopted and admired by his contemporaries, as well as by the preſent ſucceeding generation.—Rays of light iſſuing from a luminous object, proceed in ſtraight lines as long as they paſs through a uniform medium. If they meet with a tranſparent medium of different denſity, they will alſo proceed through it in ſtraight lines, provided they enter that medium in a direction perpendicular to its ſurface, otherwiſe they are cauſed to bend their courſe, ſo that beyond the abovementioned ſurface they proceed in ſtraight lines alſo; but theſe ſtraight lines form a certain angle with the ſtraight lines of their direction before they entered the laſt medium. The bending of the rays is called the *refraction* of light, and the angle that has been juſt mentioned is called the angle of refraction. See REFRACTION. Newton, having preſented a glaſs priſm, or kind of wedge, to the light of the ſun, which entered a dark room through a ſmall hole, found not only that the rays were bent from their courſe, *viz.* refracted, but he likewiſe obſerved that the image of the ſun was thereby conſiderably elongated; and this elongated image inſtead of appearing of a uniform bright white light, was reſolved into a ſeries of colours, which exactly reſembled the colours of the rainbow. This elongation of the ſolar image thus formed, is called the diſperſion of light. Theſe colours paſs from one to the other by very ſmall, and altogether imperceptible gradations; ſo that it is impoſſible to ſay where one begins and the next ends. Various methods have been tried for the purpoſe of rendering the colours of this priſmatic ſpectrum more limited and diſtinct; none, however, has been attended with complete effect. The following ſeems to be the beſt method. Let the light of the ſun paſs through a hole of about one-tenth of an inch in diameter, into a dark room. Place a ſcreen at a little diſtance from the hole (for inſtance ſix or ſeven inches) within the room, and let the middlemoſt part of the light paſs through a ſimilar hole in the ſcreen; the object of which is to prevent, in great meaſure, the ſcattered light or penumbra, on the ſides of the ſpectrum. Let the light then fall perpendicularly upon a convex lens; at the diſtance of about 10 feet, by which means a defined image of the ſun will be formed upon a ſcreen placed at the focal diſtance of the lens. Now, if a priſm be placed cloſe to the lens, ſo that the light, after having paſſed through the lens, may paſs through, and be refracted by, the priſm; then a coloured ſpectrum will be formed upon the ſcreen. The long ſides of this ſpectrum are very well defined; but its narrow terminations are ſemicircular, and its whole length conſiſts of circular coloured images of the ſun intermixed with each other, eſpecially about the middle or axis of the ſpectrum; yet the moſt predominant colours are more diſtinguiſhable from each other, eſpecially towards the ſides of the ſpectrum, ſo that their boundaries may be marked with tolerable accuracy. The glaſs priſm fit for this experiment muſt be well formed, and free from veins, ſcratches, bubbles, &c. Thoſe principal colours are ſeven in number, *viz.* red, orange, yellow, green, blue, indigo, and violet. They do not occupy equal ſpaces in the ſpectrum; but for the proportion of their breadths, and likewiſe for a more accurate deſcription of the priſmatic experiments on light, ſee the article REFRACTION.

The above deſcribed experiment with the glaſs priſm gave ſir Iſaac Newton reaſon to conclude that the white light of the ſun conſiſted of ſeven colours, which had different powers of being refracted, ſo that the red rays were refracted leſs, the orange a little more, the yellow ſtill more, and ſo on; hence the image of the ſun was converted into an oblong variegated ſpectrum. In confirmation of this theory Newton inſtituted a variety of other experiments, which were attended with remarkable reſults, and the principal of them are as follows:

If the light which has been refracted and diſperſed by a priſm, be received again upon another priſm which muſt be ſituated in a direction perpendicular to that of the former; the ſpectrum will by that means be removed from its original ſituation into a lateral one; but its breadth and its colours will remain unaltered. Now if the elongation of the beam of white ſolar light, and its reſolution into different colours, were a modification of light produced by the priſm only; then the ſecond priſm ought to expand the ſpectrum in breadth, ſo as to form a quadrilateral figure of equal ſides; but inſtead of that we find that the colours and their breadths remain unaltered.

If the refracted and diſperſed beam of ſolar light, be received upon a concave reflector, the different coloured rays will be reflected to a focus, where they will form a white or colourleſs image of the ſun. But if any of the colours be ſtopped by the interpoſition of a wire, or other ſlender and opaque body between the priſm and the reflector, then the image will become coloured with ſome mixture of colours. This proves that white light conſiſts of coloured rays, intermixed in a certain proportion, and that by a mixture of the rays of the ſeven primary colours in that due proportion, white light is produced. Therefore, white ariſes from a certain mixture of colours, and blackneſs ariſes from a ſtoppage or abſorption of all colours. This property of light and colours, may be familiarly illuſtrated by the following experiment: Divide the flat ſurface of a wheel, or the upper flat ſurface of a top, ſuch as boys uſe, by means of lines going from the centre to the circumference, into ſeven parts, having the ſame proportion that the breadths of the colours have in the priſmatic ſpectrum, and let thoſe portions be pointed reſpectively with the ſeven colours. This done, if you ſpin the wheel or the top, ſo as to cauſe it to turn very faſt, in the light of the ſun; you will find that the painted ſurface will look white; for by the quick motion of the wheel, the impreſſions of the colours in the eye become mixed, and of courſe they form a white light. Stop the wheel and the ſeven colours will appear very diſtinct.

If, when a ſpectrum is formed by the light which has paſſed through a priſm upon a ſcreen, a ſmall hole be made through the ſcreen, and the rays of one colour only be permitted to paſs through it on the other ſide of the ſcreen; then whatever is viewed in that homogeneous light, will appear of that particular colour. Thus, if the red light only has paſſed through the hole, then blood, or graſs, or milk, &c. viewed in that light behind the ſcreen, will all appear red; excepting that the blood will appear of a ſtronger red colour than the graſs or the milk. If the blue light only has been tranſmitted through the hole; then the abovementioned ſubſtances will all appear blue; and the like muſt be underſtood of the other homogeneous colours. This proves that the colours, which ſeem to proceed from coloured bodies in general, do not belong to thoſe bodies; but they are the component parts of the white light, in which thoſe bodies are viewed, and that certain bodies have the property of abſorbing ſome of thoſe coloured rays of the white light which falls upon them, and of reflecting others. Thus, graſs reflects the green rays and abſorbs the reſt, hence, the green rays coming to our eyes, render the appearance of graſs green; thus blood abſorbs every other coloured ray excepting the red, and ſo forth. Black bodies abſorb all the ſeven coloured rays, and white bodies reflect them all.

If two holes, at about a foot diſtance from each other, be made in the ſhutter of a dark room, and two priſms be uſed, *viz.* a priſm be placed to receive the light at each hole, two ſpectrums will thereby be formed upon the ſcreen; and by turning the priſms gently round their axes, the ſpectrums may be cauſed to fall one upon the other. Let the yellow of one ſpectrum fall upon the blue of the other, and at that place the mixture of thoſe two colours will appear green. Let a ſmall hole be made exactly at that place, and that green light will paſs through the hole behind the ſcreen, and will form a green circular image upon another ſcreen placed to receive it. Now, if exactly behind the perforation of the firſt ſcreen, you fix the refracting angle of a priſm, then the image upon the ſecond ſcreen will not only be moved from its place, but will appear oblong, with a yellow border at one extremity, and a blue border at the other extremity; for that ſpot or image of the ſun conſiſts of two primitive colours of different refrangibilities. The ſame thing muſt be underſtood of any other colour formed from a mixture of any two primitive priſmatic colours; for any two of thoſe colours will form, or rather will look like an intermediate colour; thus, red and yellow form an orange, blue and violet form an indigo, and ſo forth.

If the experiment be performed with one ſolar ſpectrum: *viz.* a ſingle priſmatic colour; for inſtance the green be permitted to paſs through a hole in the ſcreen, and be then received upon another ſcreen, the image will be of the ſame colour as in the preceding experiment, *viz.* green, and circular. Now, by placing a priſm behind the perforation of the firſt ſcreen, the green image will be moved from its place, but it will not be elongated nor altered in colour, becauſe this image conſiſts of one uniform primitive colour. (Newton's Opt. b. i. p. ii. prop. iv.) This remarkable experiment ſhews, that though a green may be formed from a combination, or any other priſmatic colour may be formed from a combination of the two adjacent colours; yet each of thoſe colours in the priſmatic ſpectrum, is a primitive uniform or homogeneous colour.

Notwithſtanding the conviction which naturally attends the reſult of the above-mentioned experiments, ſeveral perſons have ſuppoſed that the primitive colours of light are not ſeven, but three only; namely, red, yellow, and blue; and they have been led to this ſuppoſition, by obſerving that the painters can produce all the other colours, by mixing either all thoſe three colours together, or two of them, in due proportion.

A recent writer of eminence in the philoſophical world, (M. C. A Prieur) has ſtarted another theory. He thinks that the primitive colours. (*viz.* the components of white light) are three in number; but he ſuppoſes them to be the red, the green, and the violet; and that the other colours of the ſpectrum are formed from a mixture of thoſe; that is the yellow from the red and the green, the blue from the green and the violet, &c. See l'Annales de Chimie, Sept. 1806.

Hitherto we have treated of the formation of colours by refraction; from which it appears that the white ſolar light conſiſts of coloured rays; that whenever that light enters a tranſparent medium in an oblique direction, it is cauſed to deviate from its rectilinear courſe; and at the ſame time its component coloured rays, are ſeparated in conſequence of their different refrangibility. The next ſeries of facts, upon which the theory of colours depends, relates to the *inflection* of light, it having been found, that the rays of light are bent in their courſe, and reſolved into their component colours, not only by refraction, but likewiſe by merely paſſing by the ſurfaces of bodies. It ſeems that the rays of light are attracted by bodies, when they come within a certain diſtance of their ſurfaces, and that the coloured rays of white light being attracted more or leſs, are ſeparated from each other. A great variety of experiments relating to this inflection of light, were originally made by Newton, and have, ſince his time, been inſtituted by other able philoſophers. But, though ſeveral remarkable facts have been diſcovered; yet the preſent ſtate of knowledge does not admit of their being reducible to a ſingle principle, or to any general and comprehenſive laws.

In order to give our readers ſome idea of this property of light, we ſhall now ſubjoin an experiment related by a recent anonymous writer; referring, then, the reader to the article *Inflection of* LIGHT, for a full account of whatever belongs to it.

"Acroſs a beam," ſays the above-mentioned author, "of ſolar light, admitted into a dark chamber, through a ſmall hole in a thin piece of lead, nearly $\frac{1}{50}$ of an inch wide, I interpoſed a hair of a man's head, and receiving the beam on a ſcreen, or ſheet of white paper at a diſtance, and with an obliquity convenient for the purpoſe, I noted the following appearances.—At the termination of what may be conſidered as, and therefore may be called, a ſhadow, whoſe intenſity or darkneſs was not conſiderable; the following orders and diſtinctions of colours appeared. Firſt, and neareſt to the dark or black parts of the ſhadow, might be ſeen a diluted blue, changing into a breadth of white light, followed by breadths of yellow and red. To theſe ſucceeded an interval of diluted ſhade, then breadths of diluted violet, blue, diluted green, yellow, red; then green diluted yellow, red; diluted green, red; white, diluted red; and finally white light. Theſe are the more general orders of the colours. Of theſe orders, the three firſt were ſufficiently obvious and diſtinct; the laſt evaneſcent and requiring accommodation of circumſtances to produce, and attention to perceive them." Obſervations concerning the Inflection of Light, &c. London 1799.

The laſt ſet of facts that remains to be mentioned, as relating to colours, conſiſts of the phenomena exhibited by thin tranſparent bodies, eſpecially by thoſe of variable thickneſs. Every perſon muſt recollect to have ſeen the bubbles of a ſolution of ſoap, or of other thickning ſubſtance, exhibit a variety of colours ſimilar to thoſe of the ſolar ſpectrum, or of the rainbow. Theſe bubbles are nothing more than thin veſicles of the ſolution, whoſe thickneſs varies continually. But a variety of thin ſolid ſubſtances exhibit the like phenomenon, ſuch as plates of muſcovy glaſs, or of talc; thin plates of glaſs; metallic and glaſs plates moiſtened with a variety of fluids, &c. Newton took two object-glaſſes of teleſcopes, one of which was a plane convex, and the other a double convex one. He laid the latter on the flat ſide of the other, and preſſed them gently. Inſtantly circles of colours appeared about the point of contact, which increaſed and decreaſed both in number and in ſize, according as the lenſes were more or leſs forcibly preſſed againſt each other. The central ſpot was black, and circles of colours appeared round this ſpot, which were brighter near it than farther off. Their order, commencing from the black ſpot, was blue, white, yellow, red; violet, blue, green, yellow, red; purple, blue, green, yellow, red; green, red; greeniſh, blue, red; greeniſh, blue, pale red; greeniſh, blue, reddiſh, white. (Newton's Optics, b. ii. p. 1. Obſerv. iv.) Experiments ſimilar to the above have alſo been performed with flat glaſſes, lenſes of various curvatures, and other ſubſtances, by other philoſophers, ſuch as Moraldi, Grimaldi, Deliſle, Mairan, Mazeos, Du Tour, Muſchenbroeck, &c. See an account of their experiments in "Prieſtley's Hiſt. of Viſion, Light, and Colours." p. 6. ſect. 6. After the above ſuccinct account of the principal experiments that have been inſtituted, and the various important diſcoveries that have been made, concerning the nature of light and colours; it is proper to obſerve, that the ſubject is not only very far from being exhauſted; but that the theory ariſing from thoſe experiments and diſcoveries is doubtful in almoſt all its parts. The number of primitive colours diſtinct from one another, if ſuch do really exiſt, is not quite determinate; the attraction between the rays of light and other bodies is an hypotheſis not clearly underſtood; for it is a prevailing opinion with ſeveral philoſophers, that the rays of light are attracted within a certain diſtance, and repelled beyond that diſtance. The reflection of coloured rays from the ſurfaces of bodies is likewiſe involved in much uncertainty; it being unknown whether the reflection takes place at the very ſurface, or at a little diſtance beyond it by ſome power inherent in bodies, or, laſtly, from ſome other ſurface a little within the bodies, which ſuppoſition is founded upon the hypotheſis that all bodies are tranſparent, as far as a very ſmall part of their bulk, which hypotheſis is founded upon the obſervation that ſeveral denſe and opaque bodies, when much attenuated, become, in ſome meaſure, tranſparent; and ſuch is the caſe with gold leaf, which, when placed againſt the light, appears of a greeniſh caſt.

Notwithſtanding this uncertainty reſpecting the theory in general, the following particulars ſeem to be ſufficiently eſtabliſhed; namely, that by refraction and inflection the white light of the ſun is reſolved into coloured light. Here it may be naturally aſked whether the light of other luminous objects is not reſolved, by the like means, into the ſame colours? The obſervations made in relation to this particular are not ſo numerous, nor ſo exact as might be wiſhed; it appears, however, that ſome luminous objects yield rays of particular colours more abundantly than of other colours. The abbé Rochon having placed a priſm before an achromatic teleſcope, obſerved through it the light of the ſtars; and found that the white light of Sirius was reſolved into an oblong ſpectrum, which conſiſted almoſt entirely of three colours, *viz.* red, green, and violet. An indication of yellow was barely diſcernible between the two firſt, and a ſlight degradation between the two laſt. Through Dr. Herſchell's powerful teleſcopes moſt of the fixed ſtars ſeem tinged with peculiar colours, *viz.* ſome evidently incline to a green, others to a red, and ſo forth. The light yielded by particular combuſtibles is alſo tinged with peculiar colours, and the flame of ſpirit of wine is a ſtrong inſtance of this nature; for if common ſalt be mixed with the ſpirit, the light of its flame ſeems to be entirely deſtitute of red, yellow, and violet, and it is owing to this peculiarity that children frequently play with it in order to give a ghaſtly appearance to the ſurrounding company. When baryt (ponderous earth) is mixed with ſpirit of wine, its flame is yellow; boracic acid renders it green, and ſtrontian earth gives it a purple colour.

The phenomena of coloured bodies, as they occur to us, in general, may be diſtinguiſhed into five claſſes, *viz.* 1ſt. The colours that ariſe from evident refraction, ſuch as the colours of the rainbow, of the bubbles of a ſolution of ſoap, &c. 2dly. Thoſe of opaque bodies that are fixed. 3dly. The colours of tranſparent bodies formed by the light paſſing through them. 4thly. The colours that are changeable, according to the ſituation of the eye, like the colours of certain ſilks, feathers, flowers, thin laminæ, &c.; and 5thly. Thoſe which are changeable in conſequence of a chemical alteration of the nature of the body. We ſhall now add a few obſervations reſpecting each of thoſe five claſſes.

1. That in paſſing through a tranſparent medium, like the drops of rains, the thin pellicle of a bubble of ſoap, a thin lamina of talc, &c. the light ſhould be decompoſed or rather reſolved into colours, is eaſily underſtood, after the above-mentioned properties of the priſmatic ſpectrum; but the only circumſtance which may require explanation is, that we perceive the colours, &c. not when the refracting body is between us and the luminous object, but when both our eyes and the luminous object are on the ſame ſide. With reſpect to this, it muſt be obſerved, that a tranſparent body, like a plate of glaſs, a drop of water, &c. reflects with both its ſurfaces at the ſame time that it lets part of the light paſs quite through its ſubſtance. Direct your eyes to the ſurface of a common glaſs plate ſo as to ſee the reflection of an object, as in a looking glaſs, and if you obſerve attentively you will perceive two reflected images cloſe to each other, *viz.* one from the anterior, and the other from the poſterior, ſurface. In moſt looking glaſſes, if you place a lighted candle on one ſide, and view the reflected image of it from the other ſide, you will generally ſee a ſucceſſion of images of the candle fainter and fainter, in proportion as they recede from the principal image. The reaſon of this appearance is, that ſince both ſurfaces reflect, the image formed by the reflection of the poſterior ſurface is partly tranſmitted to the eye of the ſpectator, and partly reflected from the anterior ſurface to the poſterior one, the latter of which is again reflected, and ſo on. Now, in the caſe of the drops of rain, when they form the rainbow, the light of the ſun falling obliquely on the ſurface of the drop is refracted and reſolved into colours, in which ſtate it proceeds through the drop to its farther ſurface, from which it is partly reflected to the eyes of the ſpectator. The ſame explanation is evidently applicable to the colours of the bubbles of ſoap, thin tranſparent laminæ, and the like. See Rainbow.

2. The fixed colours of opaque bodies are in all probability owing to their abſorbing ſome of the coloured parts of white light and reflecting others; their immenſe variety ariſing from a mixture of the reflected primitive colours in various number and proportion; but it is impoſſible to ſay at preſent whether that reflection is effected at the very ſurface, or at ſome diſtance from it, either within or without the body; alſo to what cauſe the diſpoſition of reflecting certain colours in preference to others may depend upon. Mr. Delaval's experiments ſeem to indicate that the colour of opaque bodies ariſes from the light that has paſſed through a thin layer of tranſparent coloured particles, and is then reflected by the ſmooth ſurface immediately under them.

3. The greateſt number of accurate experiments, concerning the colours of tranſparent bodies, was made by Edward H. Delaval, eſq. F.R.S. (See his Paper in the Memoirs of the Lit. and Philoſ. Society of Mancheſter, vol. ii.) His experiments were performed with an immenſe variety of liquors differently tinged by metallic ſolutions, decoctions, and infuſions of flowers, reſins, gums, woods, mineral and animal matters. Thoſe liquors he placed in phials of flint glaſs, of a parallelepiped form, with an oblong cylindrical neck. "I covered," he ſays, "the bottom, and three of the ſides of each of theſe phials, with a black varniſh; the cylindrical neck and the anterior ſide, except at its edges, were left uncovered."

In order to examine what colour thoſe liquors would exhibit, either by tranſmitted or by reflected light, he viewed them through the neck of the phials, or looked into the phial through the ſide which had been left uncovered by the varniſh. But with reſpect to this latter caſe, he ſays, "the uncovered ſide of the phial ſhould not be placed oppoſite to the window, through which the light is admitted; becauſe in that ſituation the light would be reflected from the farther ſide of the phial, and would be tranſmitted through the coloured liquor; and it is obſervable that ſmooth black ſurfaces reflect light very powerfully. Now, as it is a principal object in the experiment that no light be tranſmitted through the liquors, this will be accompliſhed by placing the uncovered ſide of the phial in ſuch a direction that it may form a right angle with the window."

All the coloured liquors, which Mr. Delaval tried in the above-mentioned manner, appeared tinged with their peculiar colours, when viewed through the necks of the phials; but when he looked on that part of the liquor which filled the body of the phials, he perceived no colour whatever, the whole appearing black; which proves an important fact, namely, that tranſparent coloured liquors do not yield any colour by reflection, but by tranſmiſſion only. "If theſe liquors," he obſerves, "are ſpread thin on any white ground, they appear of the ſame colours which they had exhibited when viewed in the necks of the phials; as the light reflected from the white ground is, in this caſe, tranſmitted through the coloured medium. But when they are ſpread upon a black ground they afford no colour. The black ground, however, ſhould not be a poliſhed body; as the light reflected thereby would be tranſmitted through the thin medium on its ſurface, and be tinged by paſſing through it."

Next to the above, Mr. Delaval relates various other experiments which he made with tranſparent ſolids, *viz.* with coloured glaſſes, which he made on purpoſe, by tinging the ſubſtance of the glaſs with metallic and other matters, in imitation of real gems. Theſe coloured glaſſes exhibited phenomena ſimilar to the coloured fluids. "Having," this author ſays, "formed pieces of ſuch glaſſes, about two inches thick, I incloſed all their ſides with black cloth, except at their farther and anterior ſurface. Each of theſe pieces of glaſs vividly exhibited its colour, when viewed by tranſmitted light: but when the tranſmitted light was intercepted, by covering the farther ſurface, the anterior ſurface afforded no colour, but appeared black. When plates of tranſparent coloured glaſs, ſomewhat thicker than window glaſs, are viewed by tranſmitted light, it is well known that they exhibit their ſeveral colours. I intercepted the light, which was tranſmitted through ſuch coloured plates, by fixing a piece of black cloth contiguous to their farther ſurface. The plates, thus prepared, when placed in ſuch a direction that they form a right angle with the window, appear perfectly black; which ſhews that the coloured particles do not reflect any light."

It is hardly neceſſary to obſerve that wherever light is tranſmitted through any coloured tranſparent body, a greater part of it is loſt, than when that body is quite colourleſs; for by tranſmitting one ſort of coloured rays more copiouſly, it ſtops a great part of the oppoſitely coloured rays.

Beſides theſe tranſparent coloured bodies which have been juſt noticed, there is a vaſt gradation of others between them and thoſe that are perfectly opaque. Theſe, which are called ſemipellucid, or ſemitranſparent, exhibit a vaſt variety of phenomena ariſing from the various proportion of the opaque and the tranſparent particles which enter in their compoſition. Thus ſome appear of the ſame colour, whether viewed by tranſmitted, or by reflected light, others exhibit one colour by tranſmitted and another by reflected light; others again appear of various colours, according to their thickneſs, &c. See Newton's Opt. l. i. p. ii. prop. x.

4. The laſt paragraph may, in ſome meaſure, tend to illuſtrate the nature of thoſe coloured ſilks, feathers, &c. which change their colour according to the angle in which they are viewed, and in which the light falls upon them; other circumſtances, however, are concerned in the phenomena of thoſe bodies. Thus the ſurfaces of ſome of them are very irregular, in conſequence of which they reflect with ſome of their particles, whilſt they abſorb moſt of the light with other particles; hence, when by a lateral view, the former or the latter are placed out of the direction of the eye, the colour of the whole appears different from what it does in another point of view. Certain bodies of this ſort may likewiſe be tranſparent to a certain ſmall depth, in which caſe they become viſible partly by reflected and partly by refracted (conſequently decompoſed white) light; hence the eye of the ſpectator muſt, according to its ſituation, ſee ſome coloured rays in preference to others. The phenomena of thoſe changeable bodies, meaning with reſpect to colour according to ſituation, are far from being clearly underſtood; it is moſt probable, however, that in them all, the three principal properties of light are concerned, namely, its reflection, refraction, and inflection.

5. In the practice of various arts, wherein colours are concerned, ſuch as in dyeing, enamelling, painting in oil or water colours, &c. a change in colour of moſt of the materials is commonly obſerved, which is evidently produced by the action of the air, the fire, the oil, or other agent to which the colouring materials are expoſed, and by which they undergo different degrees of chemical alteration in their nature. This obſervation, and a deſire of inveſtigating the nature of thoſe changes, with a view of improving the practical arts dependant upon them, induced ſeveral perſons to try a variety of experiments, and Mr. Delaval, the ſame above-mentioned gentleman, who inveſtigated other branches of the preſent ſubject, became one of the greateſt labourers in this field of inquiry. Were we acquainted with the nature of thoſe particles in bodies which reflect or refract the coloured rays, and had we a ſufficient knowledge of the alterations produced on thoſe particles by the action of different agents or menſtrua, be they oils, acids, air, alkalis, &c. a juſt idea might perhaps be formed of the changes in colour, which muſt ariſe from certain combinations; but as the preſent ſtate of knowledge does not admit the formation of ſuch a theory, the whole muſt reſt upon conjecture, and the practical part muſt depend upon the reſult of particular experiments.

Sir Iſaac Newton thought, that bodies reflect and refract light, by the ſame power in different circumſtances. Alſo, that the forces of bodies to reflect and refract light, are very nearly proportional to the denſities of the ſame bodies, excepting that unctuous and ſulphureous bodies refract more than others of the ſame denſity. In ſupport of this aſſertion he relates ſeveral experiments, the reſult of which he expreſſes in a table, wherein the proportion of the ſines which meaſure the refractions of the ſeveral bodies, the denſities of the bodies eſtimated by their ſpecific gravity; and their refractive powers in reſpect of their denſities are ſtated in ſeparate columns. Mr. Delaval conceived that the denſer ſubſtances ought, by their greater refractive powers, in like circumſtances, to reflect the leſs refrangible rays; and that ſubſtances of leſs denſity, ſhould reflect rays proportionably more refrangible, and thereby appear of ſeveral colours in the order of their denſity. Agreeably to this ſuppoſition he gives inſtances of natural bodies, which differ from each other in denſity, though circumſtanced alike in other reſpects, excepting in their colour, which colour follows the order of their denſity; the denſeſt being red, the next in denſity orange, the next to that yellow, then green, &c. In ſupport of this hypotheſis Mr. Delaval made ſeveral experiments with glaſs tinged by metallic particles, in which the colour of the glaſs, in a great meaſure, correſponded to the denſity, or to the ſpecific gravity, of the metal concerned. But this ſeries of experiments is not extended to that degree, nor is it conducted with that caution, which a confirmation of the hypotheſis demanded. Mr. Delaval alſo inſtituted ſimilar experiments with coloured liquors, in which he endeavoured to ſhew, that by an incraſſation or an attenuation of their particles, their colours may be changed in one order or in the reverſe. His mode of attenuating thoſe liquors was accompliſhed, as he ſuppoſed, by the addition of acids, and that of incraſſating, by the addition of alkalies. But however ſpecious this hypotheſis may at firſt ſight appear, a ſtrict examination of facts will eaſily ſhew the fallacy of it in almoſt all its parts, and ſeveral writers have pointed out ſome of its defects, but none better than Dr. Bancroft, F.R.S. in his "Experimental Reſearches, concerning the Philoſophy of permanent Colours," vol. i. chap. i. In this excellent work, Dr. B. ſhews that Mr. Delaval has not noticed the change of nature, as well as of ſpecific gravity, which the metals undergo by their being expoſed to different degrees of heat, together with the glaſs. He alſo obſerves, that if, according to Mr. Delaval's hypotheſis, the denſeſt bodies are of a red colour, or approximating to it, platina, the heavieſt of all known metals, ought to be red; whereas it is white, like tin, and the lighteſt metals. Alſo gold, the heavieſt metal next to platina, is much farther removed from the red colour than copper, which is much lighter. With reſpect to Mr. Delaval's experiments on coloured liquors, Dr. Bancroft ſays, "inſtead of chooſing and employing mechanical means, which alone are ſuited to produce thoſe effects, and only thoſe effects, he has recourſe to mere chemical agents, whoſe actions in the ways which he ſuppoſes muſt have been almoſt doubtful, though their powers of producing other, and very different effects from what he ſuppoſes, is moſt certain. Mr. Delaval, however, adopting ſir Iſaac Newton's ſuppoſition, that acids always attenuate, and alkalis always incraſſate, prepared what he conſidered as a diſſolving or attenuating liquor; which conſiſted of water with about $\frac{1}{50}$ part of *aquafortis:* and when he wanted to leſſen the diſſolving force of this liquor, inſtead of weakening it by the addition of water (which would certainly have been the moſt obvious and unexceptionable expedient), he choſe to do it, as he ſays, by adding a ſmall quantity of a ſolution of potaſh, or ſome other alkaline liquor, and thereby produced a new compoſition, the effects of which muſt, in many caſes, prove different from thoſe of a mere diminution of the ſuppoſed diſſolving power of the former liquor. And on the other hand, when he wanted to increaſe the force of his acid liquor, inſtead of doing it by a farther addition of *aquafortis* (obviouſly the moſt proper expedient), he recurs to an addition of *oil of vitriol*, an acid poſſeſſing very different properties, and producing very different effects, on a great variety of ſubſtances, and particularly on colouring matters; of which we could eaſily allege hundreds of inſtances, but ſhall content ourſelves with only mentioning what is well known, that even the ſtrongeſt and moſt concentrated oil of vitriol (uſed to diſſolve indigo for dyeing the Saxon blue, &c.) does not deſtroy, or even weaken, its blue colour, though a very weak nitrous acid, or aquafortis, will wholly deſtroy it, and convert the indigo to a dirty brown maſs, of no uſe whatever." For farther obſervations of Dr. Bancroft on Mr. Delaval's Theory of Colours, we refer our readers to his abovementioned work. But with reſpect to the practical part of the ſubject, *viz.* the art of colouring glaſs, porcelain, &c. or the methods of forming pigments, they are requeſted to conſult the articles, PAINTING, ENAMELLING, DYEING, STAINING, CRAYONS, and PIGMENTS.

COLOUR *of the clouds*, is thus accounted for by ſir Iſaac Newton. Concluding from a ſeries of experiments, that the tranſparent parts of bodies, according to their ſeveral ſizes, reflect rays of one colour, and tranſmit thoſe of another, he hence obſerves, that when vapours are firſt raiſed, they are divided into parts, too ſmall to cauſe any reflection at their ſurfaces, and therefore do not hinder the tranſparency of the air; but when they begin to coaleſce, in order to form drops of rain, and conſtitute globules of all intermediate ſizes, theſe globules are capable of reflecting ſome colours, and tranſmitting others, and thus form clouds of various colours, according to their ſizes. Mr. Melville controverts this doctrine, in its application to the red colour of the morning and evening clouds. "Why," he ſays, "ſhould the particles of the clouds become at that particular time, and never at any other, of ſuch a magnitude as to ſeparate theſe colours? And why are they rarely, if ever, ſeen tinctured with blue and green, as well as red, orange, or yellow? Is it not more credible, that the ſeparation of rays is made in paſſing through the horizontal atmoſphere, and that the clouds only reflect and tranſmit the ſun's light, as any half-tranſparent colourleſs body would do? For ſince the atmoſphere reflects a greater quantity of blue and violet rays than of the reſt, the ſun's light tranſmitted through it ought to incline towards yellow, orange, or red; eſpecially when it paſſes through a long tract of air: and thus it is found, that the ſun's horizontal light is tinctured with a deep orange, and even red; and the colour becomes ſtill deeper after ſun-ſet." Hence he concludes, that the clouds, according to their different altitudes, may aſſume all the variety of colours at ſun-riſing and ſetting, by barely reflecting the ſun's incident light as they receive it. Edinb. Eſſ. vol. ii. p. 75. Prieſtley's Hiſt. of Viſion, p. 446, &c.

For the diſtinct propeities, &c. of the ſeveral colours, ſee BLACK, WHITE, BLUE, &c. See alſo RAINBOW, &c.

COLOUR, and **COLOUR**-*Making*, in *Calico-Printing*. The preparation of colours for calico-printing, conſtitutes one great branch of that beautiful art, and involves in it a ſeries of intereſting and important proceſſes. As an art, its operations are more dependent than almoſt any other, on thoſe minute differences and changes in the conſtitution of bodies, which it is the buſineſs of chemiſtry to inveſtigate. Hence that liability to error and uncertainty which, in the hands of the ignorant, pervades many of its proceſſes, though conducted according to long eſtabliſhed and approved formulæ. Our preſent volume would ſcarce ſuffice for the various receipts in which the art abounds; yet, in the following article, we ſhall endeavour to lay down general principles, rather than more practical directions; convinced, that by preſenting our readers with a clear and conciſe theory, deduced from ſuch practical illuſtrations, as may be neceſſary for this purpoſe, we ſhall render them a more acceptable ſervice.

The term *cola*, in calico printing, is applied not only to thoſe vegetable, animal, and mineral ſolutions, which impart their own colour to the cloth on which they are applied, but alſo improperly to thoſe earthy or metallic ſolutions, which, poſſeſſing little or no tingent properties themſelves, yet retain or fix the colours of other ſubſtances, when afterwards applied to the cloth. Thus the acetite of alumine, or printers' red liquor, when pure, is almoſt colourleſs, and only becomes red by the proceſs of dyeing, as will be explained hereafter. The acetite of iron, or iron liquor, in like manner, when uſed of a determinate ſtrength, is called *black colour*, and when weaker *purple colour*, though the cloth impregnated with theſe ſolutions becomes black or purple, only as being raiſed, like the other, in the dye-copper.

1. The colours produced by means of theſe earthy or metallic ſolutions (which, in the language of ſcience, are called *mordants*), form the moſt valuable and important ſeries, whether conſidered with regard to the almoſt infinite variety of ſhades, or to their ſolidity and durability. Theſe colours, from the mode in which they are produced, (the mordant being firſt applied to the cloth, and the colour afterwards raiſed by dyeing); are called *dyed colours*.

2. Sometimes the mordant is previouſly mixed with a ſolution of colouring matter, and in that ſtate applied to the cloth, ſo as to paint or ſtain it, at one operation, and without the proceſs of dyeing. Thus, another claſs of colours is produced, many of them poſſeſſing great brilliancy indeed, but much inferior to the former in durability. The colours called chemical, by calico printers, belong chiefly to this claſs.

3. In the third and laſt claſs, we may place all thoſe where the colouring matter is ſimply held in ſolution by an acid or alkali, and in this ſtate applied to the cloth, without the intervention of any mordant. To one or other of the foregoing claſſes, may be referred all the colours uſed in calico printing; with the exception, however, of thoſe ſyſtems of colours which have been produced by calico printers in this country, within a ſhort period, by proceſſes, and upon principles which have hitherto not been made known.

Claſs I.

The colours of this, as has been already obſerved, are produced, by firſt impregnating the cloth with an earthy or metallic ſolution, or mordant, and raiſing the colour afterwards by dyeing. In this article we ſhall confine ourſelves to the preparation of the different mordants, and the enumeration of colours they afford, with different colouring ſubſtances. The operations of the dye-houſe, and the mode of raiſing the colours in the dye-copper, will be detailed hereafter.

The two great and moſt important mordants uſed in calico printing, are thoſe that we have already noticed, *viz.* the ſolution of iron in acetous acid or vinegar, called iron liquor, and the acetous ſolution of alumine, or the earth of alum, called red liquor, or red colour, and ſometimes yellow liquor.

With theſe two ſolutions, either ſeparately applied, and of various ſtrengths, or mixed together, and in various proportions, an infinite variety of ſhades of colour are produced. Almoſt all the hues in nature may be obtained by raiſing them, and their various combinations with different colouring ſubſtances. From madder, with the acetite of alumine, or red liquor, we obtain various ſhades of red, from the darkeſt blood colour to a pink. From weld and quercitron bark, yellows, varying in intenſity from a deep orange to a pale ſtraw colour, according to the ſtrength of the mordant employed. From logwood, various ſhades of violet; from cochineal, Brazil, and Hicaragua wood, pink and crimſons of different hues; and, in ſhort, from almoſt every different colouring ſubſtance, a different ſhade of colour. With the acetate of iron, or iron liquor, of different ſtrengths, we obtain from madder all the intermediate hues between black and pale purple, or lilac. From weld and bark, olives, browns, and drabs, of various hues; from ſumac, logwood, galls, and other aſtringent ſubſtances, all the varieties of grey, from the paleſt ſhades to the deepeſt, in which all the minute differences of hue are loſt till they approach to black. Theſe various ſhades are further modified by applying two or more colouring ſubſtances to the ſame mordant, as madder and weld, for example, to the acetite of alumine, which produces orange, light cinnamon, nankeen, &c.; and again ſtill further, by mixing the mordants themſelves in various proportions, and raiſing them with either one or more of the different colouring matters. By theſe means ſhades, and varieties of colour, may be produced from a few ſubſtances only, which baffle deſcription, and for which language has no preciſe or definite terms.

The acetite of iron, or iron liquor, is variouſly prepared. In this country it is chiefly made with the pyroligneous acid, which Fourcroy has proved to be identical with the acetous. Malt acid is preferred by many on account of its being free from volatile oil and reſinous matter, with which the other abounds; but the great difference in price, and the facility with which it is obtained, has brought the acid of wood almoſt into general uſe. A ſeries of caſks filled with ſcraps and turnings of iron upon which the acid is poured, is almoſt the only apparatus neceſſary for making iron-liquor; yet when the conſumption is great, or when it is prepared for ſale, vats capable of holding ſeveral hundred gallons are ſubſtituted for caſks, and the acid is kept in a ſtate of circulation through the iron by means of pumps. The ſaturation is much accelerated by this motion, which prevents any depoſition on the ſurface of the iron which might defend it from the action of the acid, and alſo brings freſh portions of unſaturated acid more frequently in contact with the metal. In a few weeks, ſooner or later in proportion to the ſtrength of the acid, the ſaturation is completed, and the liquor is then removed from the vat into caſks for uſe, and freſh acid poured upon the iron as before. This is an eaſy and ſimple mode of making iron liquor, and as it requires but little trouble and attention, is the one moſt generally in uſe. The precautions neceſſary to be obſerved are, that the acid, if it be the pyroligneous, ſhould not be uſed too ſoon after its preparation. It holds much eſſential oil and reſin in ſolution, part of which ſeparates on being kept a few weeks, and the clear acid may then be drawn off. It may be ſtill further freed from reſin by boiling; a portion of eſſential oil is thus thrown off, and the reſin, if held ſuſpended, is precipitated after ſtanding ſome time. We ſhall have occaſion to recur to this ſubject again, when we come to treat of the pyroligneous acid, and its formation, under the article *Diſtillation of* Wood. It is neceſſary alſo, that the iron ſhould be perfectly clean and all of it malleable. Caſt iron is not ſoluble in acetous acid. Hoop iron cut into lengths of from eight to ten inches is preferable to any other. It is readily cleaned and more eaſily taken out of the vat, and returned into it again than miſſhapen maſſes ſold under the name of old iron. When malt acid is employed, ſimple heating and waſhing is ſufficient to free it from any foulneſs it may have contracted in the vat; but when the pyroligneous acid has been uſed, it becomes ſo coated with reſin on its upper ſurface after a ſecond or third ſolution, as to prolong the period of ſaturation to twice or thrice its uſual length. In this ſtate it muſt be removed from the vat and heated to redneſs in oven, through which there is a current of air. The reſin is conſumed, and the iron by heating is freed from any remains of carbonaceous matter that may adhere to it, and is again ready for the vat.

The only objection to this mode of making iron liquor is the time required to ſaturate the acid, which to thoſe, whoſe conſumption is very great, or who manufacture it for ſale, is oftentimes of importance. Different proceſſes have therefore been deviſed to remedy this inconvenience, in many of which the ſaturation is accelerated by means of heat which is applied in various ways, as beſt ſuits the convenience of the manufacturer; but the moſt expeditious mode is that of preſenting the iron to the acid in a ſtate of oxydation, by which means the ſolution is effected immediately. Calico printers have long been in the habit of uſing an extemporaneous acetite of iron, formed by mixing together ſolutions of acetite of lead and ſulphate of iron. A very pure acetite of iron may be obtained by this means, but the price of acetite of lead renders this mode too expenſive for general uſe. By forming a ſolution of lead, however, in pyroligneous acid and decompoſing it with ſulphate of iron or copperas, an iron liquor may be obtained ſufficiently cheap to render this proceſs advantageous in many caſes, though ſtill more expenſive than the ordinary mode. A patent was lately taken out for making iron liquor by a proceſs ſomewhat ſimilar to this, which, however, we underſtand has not anſwered the expectation formed of it. A ſolution of lead in pyroligneous acid is digeſted on clear metallic iron. The iron becomes oxydated at the expence of the lead and is diſſolved, whilſt the lead is precipitated in the metallic ſtate, and may again be uſed for a freſh ſolution. All theſe modes are evidently more expenſive than the ordinary one of ſimple ſolution of metallic iron in pyroligneous acid, and the only conſideration with the manufacturer is, whether this extra expence is counterbalanced by the economy of time or not.

The proceſs adopted ſome years ago by Mr. Thomſon, is perhaps the moſt expeditious, and next to the common mode, the moſt economical of any yet in uſe. It conſiſts in ſaturating the pyroligneous acid with quicklime, and pouring the clear boiling ſolution on as much ſulphate of iron or copperas as will precipitate the whole of the lime. A caſk of iron liquor may be made by this mode in a few hours, and when care has been taken rightly to proportion the ingredients ſo as to produce complete decompoſition, it is inferior to no ſolution whatever in any of its properties.

The properties of the acetous ſolution of iron fit it eminently above all others for the purpoſe of the calico printer, and having detailed its preparation we ſhall endeavour to point out in what this ſuperiority conſiſts.

The acetite of iron exiſts in two ſtates, dependent on the quantity of oxygen combined with the iron. When pure, and recently prepared, it is of a pale greeniſh hue, but by expoſure to air ſoon becomes tinged with brown. In this ſtate the iron is at its loweſt point of oxydation, ſtrongly attractive of oxygen, and if precipitated by an alkali, of a deep green colour. By expoſure to the atmoſphere, and conſequent abſorption of air, the ſolution paſſes to a deep red brown, and, if concentrated, depoſits orange oxyd of iron, and becomes ſtrongly acidulous. With this exceſs of acid, the ſolution now becomes permanent; the iron is almoſt wholly at the maximum of oxydation; and, when precipitated, of a dark red colour.

The ſame takes place only in a leſs degree, and more ſlowly with the ſulphuric and muriatic ſolutions of iron. Of a pale greeniſh hue in their recent ſtate, they gradually attract oxygen from the atmoſphere, and become ſlightly red, depoſit red oxyd of iron and paſs to a ſtate of acidity, at which the ſolution becomes permanent, and the oxydation of the iron proceeds no further.

If the ſolutions, properly thickened with gum or flour, are applied to cloth, the ſame change takes place, but with more rapidity, from their diffuſion over a thin ſurface, and more complete expoſure to the air. The aqueous and volatile part of the ſolution ſpeedily evaporates, and as the oxydation goes on, the oxyd of iron is depoſited on the cloth, and a portion of acid ſet free. When this acid is volatile, as is the caſe with the acetous, and alſo in a great degree with the muriatic, it is diſſipated. The oxydation of the iron then goes on, freſh portions of acid are again liberated and drawn off till the whole of the ſolution is decompoſed, and the oxyd of iron depoſited in the cloth. When the acid is not volatile, however, as is the caſe with the ſulphuric, the firſt portions of acid that are liberated not being drawn off, the oxydation proceeds more ſlowly till the exceſs of acid becomes ſo great as wholly to interrupt it, and great part of the iron in the operation of rinſing is again carried off the cloth. Another and more ſerious inconvenience attending the uſe of the ſulphuric ſolution is its action on the cloth itſelf. The diſengaged acid being in a ſtate of great concentration acts upon its fibres, weakens, and at laſt deſtroys them. The ſame takes place with the muriatic ſolution alſo, for though the exceſs of acid is ſlowly diſſipated, yet it has ſufficient time and concentration to act very powerfully, and is, if poſſible, ſtill more deſtructive than the ſulphuric, ſince its action is not confined to the part on which it is applied, but from its volatility extends over the whole ſurface of the cloth.

It is neceſſary, therefore, that the acid ſhould be not only volatile, but harmleſs in its action on the vegetable fibre, which conditions are more completely fulfilled by the acetous than by any other ſolution whatever. From the preceding obſervations on the properties of the acetite of iron, and the changes it undergoes on the ſurface of the cloth, may readily be deduced the reaſons for that expoſure to heat and air which calico printers have, from long experience, found neceſſary to goods printed with this ſolution. By expoſure to air the iron becomes oxygenated and depoſited on the cloth, whilſt the heat favours the liberation of the acid, and accelerates the proceſs. From what has gone before it may alſo be inferred, that the acetite of iron ſhould be uſed in its recent or *green* ſtate, ſince in that ſtate the acetous acid is capable of holding a greater quantity of oxyd of iron in ſolution, and that conſequently after its ſaturation and removal from the iron, it ſhould not be too much expoſed or agitated in contact with the air. On this account, alſo, it is wrong to pump the liquor in the vats too much when it approaches the point of ſaturation, ſince the oxygenated iron is almoſt all precipitated, and freſh portions immediately diſſolved, ſo that the liquor might in time be rendered quite thick with precipitated oxyd of iron.

The preceding ideas are at variance with the general opinion reſpecting the ſtate in which the acetite of iron ſhould be employed. All the ſpeculative writers, and even many well acquainted with the proceſſes of calico printing, recommend the oxygenation of the ſolution by expoſure to air and removal from the iron, as eſſential to the goodneſs of the iron liquor. Even Berthollet, in the laſt edition of his "Elements of the Art of Dyeing," has fallen into the ſame miſtake, the ſource of which, and the facts which ſeem to countenance it, we ſhall point out in a future article.

It is an object of importance to the calico printer to know the preciſe ſtrength of his iron liquor, and to be able to aſcertain this at all times, with little trouble or chance of error. Great miſchief and inconvenience often ariſes from uncertainty in this reſpect, eſpecially in the pale ſhades of purple, which are obtained from madder, with diluted acetite of iron. The hydrometer has been objected to, as indicating not merely the quantity of iron in a ſolution, but alſo the eſſential oil, reſin, and mucilage which theſe impure ſolutions often contain. This objection, however, only applies where the ſame inſtrument and graduation is employed to aſcertain the relative ſtrengths of iron liquors, prepared with different acids, as the pyroligneous which contains much eſſential oil and reſin, and malt acid which abounds in mucilage. In this caſe the hydrometer may indicate great differences in ſolutions containing equal quantities of acid and iron, but varying in the quantities of mucilage, oil, or reſin. Iron liquor, however, prepared conſtantly by the ſame proceſs, and from the ſame acid, varies ſo little in the relative proportion of its ingredients, that the hydrometer may be uſed to aſcertain its ſtrength in preference to any other mode whatever; provided the neceſſary precautions are uſed to correct any error ariſing from variation of temperature.

In a work of this kind, not illuſtrated by actual ſpecimens, and without reference to ſome particular kind of iron liquor, it is impoſſible to point out the ſpecific gravities of the different ſolutions required for producing the various ſhades, we have enumerated. An acetite of iron, of ſpecific gravity 1.047, with madder or logwood, will produce a black, and with weld or ſumac an olive, and diluted with ſix, eight, or ten times its bulk of water, various ſhades of purple, drabs, or olives, according to the colouring matter employed. A ſtandard ſolution of iron once obtained, the neceſſary ſtrength for producing the different varieties of colour is eaſily aſcertained by actual experiment, and to this we muſt refer our readers.

When thickened with flour or gum, and tinged with a decoction of logwood or Brazil, the better to enable the workman to obſerve the progreſs and ſtate of his work, it forms, as we have before obſerved, the printers black colour, a purple colour, &c. according to the ſtrength of the ſolution and the purpoſe it is intended for. Various ingredients were formerly added to iron liquor, to improve its quality, or vary the hue of colour it produced. Verdigriſe and copperas were added to the ſolution intended for black; and ſal ammoniac or nitre to the diluted ſolutions for purple. Theſe are, however, now almoſt univerſally laid aſide, as being for the moſt part uſeleſs, and often hurtful: the ſimple acetite of iron being found to anſwer every purpoſe of the more complicated and heterogeneous ſolutions.

The *acetite of alumine*, or red liquor, is always prepared by the decompoſition of alum, by an earthy or metallic ſalt, ſince the aluminous earth is not ſoluble in acetous acid, except in its newly precipitated and minutely divided ſtate. The pureſt ſolution, and that which is generally uſed for the fineſt and moſt delicate colours, is produced by decompoſing alum with Dutch ſugar of lead, generally in the proportion of two parts by weight of the former, to one of the latter. The proportion of the two ſalts, and alſo the quantities of each gallon, as uſed by different calico printers, vary yet with little difference in effect. The alum in general predominates ſo far as completely to ſaturate the liquor. The printers' aluminous mordant therefore is a compound ſolution. It is an aceto-ſulphate of alumine, conſiſting of a ſaturated ſolution of common alum, and more or leſs acetite of alumine, according to the quantity of ſugar of lead employed. In the neighbourhood of London, the proportions are 6lb. of alum, and 3lb. of ſugar of lead to a gallon of water: when theſe are completely diſſolved, one ounce of Spaniſh white is added, and the whole briſkly ſtirred till the effervеſcence has in great meaſure ſubſided. In a few hours the ſolution becomes clear, and forms a ſtandard liquor from which, by greater or leſs dilution, may be obtained all the various ſhades of red, yellow, &c. already enumerated. In the above formula the proportion of alum is ſomewhat too great, a part of it remains undiſſolved, or immediately recryſtallizes, and falls to the bottom along with the precipitated lead. This exceſs of alum is however ſtrongly inſiſted on by many calico printers, as eſſential to the purity of the mordant, from an idea that the *pureſt* part of the alum only is taken up in the ſolution. This fact however may be readily diſproved by employing this undiſſolved or recryſtallized alum in the formation of freſh ſolutions, whoſe purity will be found in no reſpect inferior to the former. The purity of the alum and ſugar of lead, and eſpecially their being free from iron, is of great importance in the preparation of this mordant, and on this account the Dutch ſugar of lead is preferred; but its high price renders it too expenſive except for the pale reds of light chintz, and other kinds of work, whoſe great delicacy in the red tints is required. A ſubſtitute for it has been found in the ſolution of litharge in vinegar, or pyroligneous acid, which is afterwards decompoſed by the addition of alum, and the exceſs of acid neutralized by Spaniſh white as in the former caſe. Great part of the acetite of alumine manufactured and ſold under the name of red liquor is prepared in this manner. It is in general uſed for yellows, dark ſhades of red, and for thoſe compound mordants into which the acetite of iron enters, and when its purity is of courſe of little conſequence. The acetite of lime has long been ſubſtituted with great advantage by the writer of this article for the ſolution of lead, and its uſe is becoming daily more known and extended. When carefully prepared, it is ſcarce inferior to the beſt ſugar of lead, and the impure ſolutions anſwer equally with the beſt, for the compound mordants before mentioned. The theory of theſe proceſſes is the ſame in all. The object being to obtain a ſolution of alumine or earth of alum in acetous acid. On mixing acetite of lead, and ſulphate of alumine together, a change of baſes takes place; the ſulphuric acid unites with the lead, and falls down in the form of a white heavy precipitate, whilſt the earth of alum combines with the acetous acid, and remains in ſolution. The ſame takes place with the ſolution of litharge in pyroligneous acid, which is indeed an impure acetite of lead, and when the acetite of lime is employed inſtead of lead, the ſulphuric acid and lime unite and form an inſoluble powder, which ſubſides, though leſs quickly than the other, whilſt the acetite of alumine remains in ſolution above; the addition of the Spaniſh white is neceſſary to ſaturate a ſmall exceſs of acid which exiſts in the ſolution. This exceſs is taken up by the lime, and immediately converted into acetite of alumine, by the decompoſition of a freſh portion of alum.

The acetite of alumine when pure, is almoſt colourleſs. It has a ſlight acetous ſmell, and when boiling throws off acetous acid in great abundance, and depoſits a portion of alumine. When evaporated it acquires a thick gummy conſiſtence, but does not cryſtallize a property which gives it a decided advantage over common alum as a mordant. It unites readily with gum, but when concentrated and holding much alum in ſolution, forms with flour a watery pulpy kind of paſte, which has little adheſion, and from which the fluid ſoon ſeparates. The ſulphuric ſalts have indeed all a diſpoſition to injure the thickening quality of flour.

The affinity of cotton for the earth of alum, is ſo ſtrong as to ſeparate it from its combinations even with the mineral acids. When a ſolution of common alum properly thickened is applied to cloth, a portion of alumine unites with it, and the acid, which held it in ſolution, is ſet free. When this is accumulated to a certain degree, it prevents any further decompoſition, and in rinſing carries off the greater part of the earth again. When the acid however is volatile, like the acetous, and is diſſipated as ſoon as diſengaged, there being no longer any obſtacle, the decompoſition goes on till the whole of the acid is driven off, and the alumine combined with the cloth. In the infancy of calico printing, and before the theory and conſtitution of the different mordants was properly underſtood, a variety of ſubſtances were added to the ſolution, ſome of which are retained to this day. Verdigriſe in the proportion of two ounces to a gallon, is recommended by many as tending to exalt the hue of yellows, and may in ſome caſes be uſeful. Corroſive ſublimate has been but lately laid aſide, and the nitro-muriate of tin was long thought to give fixity and brillancy to reds, when uſed in a ſmall proportion with the aluminous mordant. In general, however, the aceto-ſulphate of alumine is found adequate to every purpoſe of the calico printer; we ſhall not, therefore, perpetuate error by detailing any of thoſe unmeaning mixtures which are ſtill retained by the ignorant and prejudiced. Theſe two mordants, the acetites of iron and alumine, and their various combinations, are thoſe only in general uſe in calico-printing, for producing colour of the firſt claſs. This application is ſo extenſive, and at the ſame time ſo ſimple, as to ſuperſede the neceſſity of any other. The ſolutions of copper are ſometimes uſed as mordants, but they afford colours of little ſolidity. The ſolutions of tin have alſo been employed, but we ſhall ſpeak of theſe and other earthy and metallic ſolutions which have been uſed with partial ſucceſs, when we come to treat of mordants in general.

Claſs II.

In this claſs the colours are produced by combining a ſolution of colouring matter with ſome earthy or metallic ſalt, capable of giving it fixity when applied to the cloth. The mordant and colouring matter are here applied at once, and the cloth is painted, as it were, or ſtained, with the colour it is intended to retain, and requires, in general, no farther operation than that of rinſing, to free it from the paſte or gum with which it was thickened.

The colour of this claſs poſſeſſes, as we have before obſerved, in general great brilliancy, but wants that ſolidity and fixity which characteriſe the colours of the former claſs. The union of the mordant with the cloth is weakened by its previous combination with the colouring matter, and not being favoured by heat, as in the former caſe; the triple combination of vegetable fibre, mordant, and colouring matter, wants that ſolidity which is ſo neceſſary to conſtitute what is called a faſt colour.

Many of theſe, however, are ſufficiently durable to be partially introduced, and intermixed with other colours of greater durability, and ſome are indiſpenſably neceſſary, as no better mode has yet been deviſed of producing them. When the chemiſt's art ſhall have diſcovered means of giving fixity to colours thus topically applied, the art of calico printing will have arrived at perfection. Syſtems of colours may then be combined, which are at preſent incompatible, and the tedious operation of dyeing and bleaching, with their attendant difficulties, be baniſhed from the art. Nor is the hope ſo chimerical as might at firſt be imagined; ſeveral of the moſt uſeful and permanent colours are of this deſcription, as will be ſhewn hereafter.

We ſhall content ourſelves with deſcribing the leading and moſt uſeful colours of this claſs, giving, at the ſame time, the theory of their conſtitution. The mere enumeration of all the varieties that have or may be formed, would be endleſs, and foreign to our purpoſe.

Chemical Black.

This is the moſt uſeful colour of the claſs, and one of indiſpenſible neceſſity in certain combinations of colours, where, for inſtance, it is mixed with drab, olive, and yellow, raiſed in the dye-copper with weld quercitron bark, or any ſimilar colouring matter, and where the preſence of any ſubſtance, ſuch as logwood or madder, capable of producing a full black, would be ruinous to the other colours. A deep olive, approaching to black, might, indeed, be produced, by employing a ſtrong iron liquor, as mordant, and uſing ſumac in the dye-copper; yet as this would bear no compariſon in point of intenſity with the madder or logwood black, and as the force of the colouring in ſuch courſe of work greatly depends on contraſt, the topical or chemical black, which has all the intenſity required, is almoſt conſtantly employed. The conſtitution of this black is pretty nearly the ſame in all the different formulæ in uſe. It conſiſts always of a ſolution of iron combined with a ſolution of colouring matter generally of an aſtringent nature. On the right proportion of theſe two ſolutions, and on their due ſpecific gravity or ſtrength depends, in a great meaſure, the goodneſs of the black.

1. If to a decoction of Aleppo galls, in five times their weight of water, made into a paſte with flour, a ſolution of iron in nitrous acid of ſpecific gravity 1.25 be added, in the proportion of one meaſure of nitrate of iron to eighteen or twenty of the former, a black will be formed fit for almoſt all the purpoſes of calico printing, and poſſeſſing the chief requiſites of this colour, namely, tolerable fixity, and a diſpoſition to work well with the black.

2. In lieu of nitrate of iron, ſome calico printers employ copperas, in the proportion of one pound to a gallon of the decoction of galls. Half the copperas is directed to be diſſolved in the gall-liquor before it is thickened with flour; the remaining half, diſſolved by heat in as much aquafortis as will cover it, is added afterwards. This black has tolerable fixity, but does not work ſo well as the preceding.

3. Copperas diſſolved in various proportions of from four to twelve ounces per gallon, will form, with decoction of galls or logwood, blacks of leſs ſolidity indeed than the former, yet applicable, nevertheleſs, in many caſes where the others are not.

The conſtitution of the two laſt-mentioned blacks differs ſomewhat from the firſt. We ſhall point out this difference, and explain, as conciſely as poſſible, the rationale of the foregoing proceſſes.

When a ſolution of iron in nitrous acid is added to a decoction of galls, as in the firſt example, the ſolution is decompoſed, the iron unites with the gallic acid and tanning principle, whilſt the nitrous acid is diſengaged. This is proved by the blackneſs which the ſolutions aſſume immediately on being mixed. The diſengaged acid, however, ſhortly re-acts on the new compound, the blackneſs gradually diſappears, and in a few days, if the nitrate of iron has been added in proper quantity, the paſte, inſtead of black, is of a dirty olive green. If the proportion of nitrate of iron be greater than $\frac{1}{15}$, this change will be effected ſooner; and if ſo high as $\frac{1}{10}$, the paſte, when applied to the cloth, will be a bright orange, like the acetite of iron. By expoſure to heat and air, this colour generally deepens, becomes grey, and at laſt a full black. In this ſtate it is permanent, and adheres powerfully to the cloth. Theſe changes of colour depend on the ſolution of the tannate and gallate of iron in the diſengaged nitrous acid, and the evaporation of the acid when expoſed to heat and air on the cloth. This ſolution of the tannate and gallate of iron is indeed an eſſential requiſite in the goodneſs of the chemical black. If the diſengaged acid is not ſufficient to effect this, or if it is in too great a ſtate of dilution, the colour has but a feeble adherence to the cloth; it is not preſented in a ſtate favourable to its union with it, ſince the combination into which the iron has entered is inſoluble in water. It lies merely on the ſurface, but does not penetrate its fibres, and yields readily in the various operations to which it is ſubjected. The chemical black, therefore, of the firſt example is a ſolution of the tannate and gallate of iron in nitrous acid.

The black of the ſecond, but more particularly of the third example, differs from the preceding in the circumſtance of the iron in the ſolution being in a leſs oxygenated ſtate. We may conſider this black in its recent ſtate as a mixed ſolution of green ſulphate of iron, and gallic acid, and tanning principle; for the decompoſition of the ſulphate is not complete till by expoſure to air on the cloth the iron becomes fully oxygenated. When this black is recently applied to the cloth, it is of a pale greyiſh colour, has little fixity, ſimple rinſing in cold water being ſufficient to fetch nearly the whole away. By gradually abſorbing oxygen, it becomes deeper, and at laſt black. The ſulphuric acid has no longer any action on it, and is removed in the firſt operation in which it is immerſed in water.

The decoction of galls uſed for chemical black is variouſly prepared. Many calico printers infuſe the galls cold in caſks of vinegar, or pyroligneous acid, ſuffering them to remain ſeveral months, occaſionally drawing off the lower part, and returning it on the galls. Others ſteep them in urine. Both theſe modes are vicious, particularly the laſt. Simple boiling in water, till all the ſoluble matter is extracted is ſufficient, taking care to incloſe the galls in a ſack, that when ſoft they may not render the decoction thick.

Grey.

By diluting the chemical black of the firſt example with once, twice, thrice, &c. its bulk of water, and thickening the ſolution with gum, various ſhades of grey are obtained, which require rinſing off in water only, and the deeper ſhades of which have tolerable permanence.

The theory of theſe mixtures is the ſame as of the black, from whence they are derived. On the addition of water to the olive-green ſolution, mentioned in the preceding article, the colour inſtantly becomes deep purple, approaching to black. This is occaſioned by the dilution of the free acid, which being no longer able to hold the tannate and gallate of iron in ſolution, ſets part of it at liberty, which inſtantly regains its colour. For the reaſon already aſſigned, this has leſs adherence to cloth than that in which the ſolution is more perfect. The addition of a ſmall quantity of nitrous acid effects this. The olive-green colour of the ſolution is reſtored, which, by expoſure to the air, and conſequent evaporation of the acid, diſappears, and leaves the tannate and gallate of iron more firmly fixed on the cloth. The complete precipitation of the combination is afterwards effected in the operation of rinſing off in water.

Yellow.

The falſe or chemical yellows are generally prepared with decoctions of French or Turkey berries, and ſometimes with quercitron bark. The latter ſubſtance produces pale yellows or ſtraw colour, but does not afford the deep bright orange yellow of the berries. Dr. Bancroft, to whom the public is indebted for the introduction and knowledge of this moſt uſeful dyeing drug; indeed, aſſerts the contrary in his work on "Permanent Colours;" and has given a receipt for the bark-yellow, which has, however, never ſucceeded in our hands.

Berry-yellow. Boil two pounds of good berries, ſlightly bruiſed, in a gallon of water during three hours, taking care to replace, from time to time, the evaporated water with liquor obtained from the ſecond boiling of a former quantity of berries. When the liquor is cool, add to it eight ounces of alum, and if it is intended for the block thicken it with flour. If it is meant for thoſe ſmall objects in printed goods, which are generally touched with the pencil, two ounces of ſugar of lead ſhould be added with the alum, and the colour thickened with gum dragon. This yellow is generally paſſed through lime water as the firſt part of the operation of rinſing; by this means the greater part of the earth of alum, which would otherwiſe have been carried off in the operation, is precipitated on the cloth, and the colour conſiderably heightened.

When this operation of liming cannot be performed without injury to ſome other colour, a greater proportion of ſugar of lead ſhould be added. This decompoſes the alum, and forms an acetite of alumine, which being more readily decompoſed by the colouring matter and the cotton than ſulphate of alumine, does not require the aſſiſtance of an alkaline ſolution to precipitate it on the cloth.

The proportion of berries above directed is for a full yellow; one-fourth or one-third leſs will form, with the ſame quantities of ſalts, yellows of great brightneſs. Some calico printers add a ſmall quantity of nitrate of copper to the yellows intended to be ſimply rinſed off without liming. This heightens the colour, but what is gained in intenſity is loſt in brightneſs; for if the ſolution of copper be added in ſufficient quantity to produce any very perceptible effort, it imparts a dulneſs to the hue which is very detrimental. This is the invariable effect of copper in any ſhape, whether the acetite, ſulphate, or nitrate of copper be employed.

Bark yellow. For a lemon or ſtraw colour, it will be ſufficient to make a decoction of bark by boiling from four to ſix pounds in as much water as is neceſſary during two hours, and after evaporating down the decoction to one gallon, add to it two ounces of ſugar of lead, and eight ounces of alum. If not limed, the proportion of ſugar of lead ſhould be doubled. For ſtrong yellows, Dr. Bancroft directs the addition of both nitrate of copper and nitrate of lime in quantities ſo great, as near ſeven ounces of the former to a gallon of colour. Experience, however, though it has done juſtice to the merits of Dr. Bancroft's diſcovery of the uſe of quercitron bark, has not verified the expectations he had formed of it as a ſubſtitute for the Turkey berries in the topical or chemical yellow.

The conſtitution of theſe colours, whether formed with the ſulphate and acetite of alumine, or with the ſolutions of copper is the ſame. Alumine, or the earth of alum, and the oxyd of copper, have an affinity both for colouring matter and vegetable fibre. They form the connecting link between theſe ſubſtances, which would otherwiſe counteract a feeble union. When a ſolution of alum is added to a decoction of berries or of bark, a ſlight precipitation takes place by the union of a portion of colouring matter with the earth; the greater part however remains ſuſpended or held in ſolution by the acid of the alum. When applied to the cloth the farther decompoſition of the ſalt is aided by the affinity of this ſubſtance for alumine, and, when the acid is volatile, as the acetous for example, by its conſequent evaporation. The ſame takes place with the ſolutions of copper. The operation of rinſing farther aids the precipitation of the colouring matter and alumine, by thus largely diluting with water; and laſtly, when the goods are previouſly paſſed through the lime tube, the decompoſition is complete, the laſt portions of earth or oxyd are precipitated, and the colour thereby conſiderably exalted.

The ſolutions of tin are capable of forming very bright and beautiful yellows, with decoctions of different yellow colouring ſubſtances; but the exceſs of acid which theſe ſolutions neceſſarily contain, and their powerful action on the cloth, renders their application leſs general than the preceding. The ſolution of tin moſt proper for yellows is the muriatic, and is formed by digeſting, in a low heat for ſeveral days, the common muriatic acid, or ſpirits of ſalt, on fine grain tin. This ſolution forms, with bark, a pale and lively yellow, and with berries a yellow bordering more on orange. Theſe ſpirit yellows, however, as they are improperly called, are ſeldom uſed except upon dyed grounds, and of this preparation for ſuch purpoſes we ſhall treat at large under the head of *Diſcharged* Work.

Blue.

The only blue belonging to this claſs is that produced by combining the colouring matter of logwood with the oxyd of copper. It is but ſeldom uſed ſince the mode of dipping China blue has become generally known; and indeed its want of durability renders it of little value. It may be produced by combining almoſt any of the ſolutions of copper with a decoction of logwood.

1. Boil two pounds of logwood in a gallon of water, and to the decoction, thickened with gum, add eight ounces of ſulphate of copper.

2. To a decoction of logwood as above, add two ounces of ſulphate of copper, and two ounces of verdigriſe.

Their colours may either be rinſed off or limed, as beſt ſuits the ſtyle of work. The theory of theſe combinations is the ſame as the preceding.

Green.

The chemical or falſe green is a compound colour, and conſiſts of a mixed decoction of logwood and berries, or bark, and a ſolution of copper. Though fugitive, its uſe is in ſome degree authorized by the impoſſibility of obtaining a green of greater durability that can be applied in figures with the block. The faſt green of the calico printers is the product of two operations, and is of courſe limited in its application, and tedious in its uſe. The production of a faſt green at one operation, or rather by one application to the cloth, either with the pencil, block, or preſs, is one of the great *deſiderata* of calico printing.

1. One pound of logwood and two pound of berries boiled together during two hours, and ſtrained whilſt hot

upon two ounces of ſulphate of copper, and two ounces of verdigriſe, and thickened with gum, form a good and lively green, the hue of which may be varied at pleaſure by the increaſe or diminution of the proportion of logwood. To this ſome calico printers add two ounces of common ſalt, and two ounces of ſal enixon or acidulous ſulphate of potaſh.

2. To one meaſure of blue of the firſt example in the preceding article, add two, three, four, &c. meaſures of a decoction of bark, made by boiling ſix pounds as before directed for the yellow, and to which, when reduced to one gallon, two ounces of ſulphate of copper, and two ounces of verdigriſe have been added. The tone of the green depending on the relative proportions of blue and yellow, it is, in general, beſt to keep the two decoctions ſeparate, to be mixed, when wanted, in ſuch proportions as may beſt ſuit the purpoſe required. The theory of theſe mixtures is the ſame as of the blue and yellow already deſcribed. To the eye of the mere ſpeculative chemiſt, the addition of common ſalt and acidulous ſulphate of potaſh in the firſt example, may appear unneceſſary and unmeaning. They indeed affect little, either the hue or fixity of the colour, but experience has proved that this addition facilitates its working with the block, more eſpecially when thickened with gum dragon. The cauſe of this, in the particular inſtance before us, is perhaps not very clear. The ſulphuric ſalts in general, ſuch as the ſulphates of alumine, iron, and copper, are all unfavourable to working, as their ſolutions, eſpecially when concentrated, neither thicken well with flour nor gum. A ſaturated ſolution of copperas cannot be thickened with flour, nor can a ſtrong ſolution of the aceto-ſulphate of alumine, in which the alum is in great exceſs; even with gum it unites with difficulty. But if to a ſolution of copperas, which refuſes to form a paſte with flour, a ſmall portion of nitrate of iron be added, the whole forms a good and ſubſtantial paſte that works admirably with the block; and half a pound of common ſalt added to the aceto-ſulphate of alumine has a ſimilar effect. In the inſtance more particularly before us, the addition of common ſalt forms a muriate of copper by the decompoſition of the ſulphate; but this laſt is in too ſmall a quantity to affect the working of the colour very ſenſibly. The cauſe of theſe effects is to be ſought for in the very complicated play of affinities, which exiſt in ſuch compounds, and which future inveſtigation and diſcovery may perhaps unfold. The ſpeculative philoſopher, who is ignorant of the minute details of an art, that involves in it conſideration and difficulties, unſuſpected in the laboratory, will hence learn to ſuſpend his judgment in deciding on the merits of a formula, till experience ſhall have proved the inutility of thoſe ingredients which theory would reject as abſurd.

But to return to our ſubject, there is a wide field open for experiment and diſcovery in the production of greens, into which logwood does not enter. A calico printer near London, celebrated for his ingenuity and invention in colours of this claſs, has long employed a green which, from its beauty and durability, when compared with the foregoing colours, indicate the preſence of indigo as a conſtituent part. Pruſſian blue in a minutely divided ſtate, and mixed with bark or berry-yellow has been employed; but the blue in this caſe has ſo little adherence to the cloth, that mere mechanical force, the operation of rinſing and waſhing is ſufficient to diſengage it. With one or other of theſe ſubſtances, however, it is likely that greens much ſuperior in beauty, and probably alſo in durability to thoſe generally in uſe, might, by a ſeries of patient and well conducted experiments, be readily obtained.

Pink.

The pale, and more delicate ſhades of red, belonging to this claſs, are chiefly ſought after in calico printing. They are employed in giving relief or effect to other admixtures of a more ſober caſt, and all the ſkill of the colour-maker is exerted in giving them brilliancy and richneſs of tint. They are chiefly produced from decoctions of Brazil, nicaragua, or peachwood, and cochineal, raiſed and fixed on the cloth with ſolutions of tin, rarely with the aluminous mordants, though delicate and lively colours may be produced this way.

The nitro-muriate of tin is chiefly employed, though the relative proportion of the two acids, and their degree of ſaturation with tin, varies almoſt with every calico printer. The ſolution itſelf, made according to eſtabliſhed rule, and with the ſame properties, varies ſo conſiderably at different times, as wholly to alter the nature of its compounds, without any apparent cauſe of failure. The ſource of this diſcordance is to be ſought for in the conſtitution of the ſolution itſelf, which, from cauſes that we ſhall endeavour to explain, is ſubject to conſiderable variation.

Firſt, from the ſtrength or concentration of the acids employed, which are ſeldom uniform or conſtant; muriatic acid from the ſame manufacturer varying often in ſpecific gravity from 1.12 to to 1.18, and nitrous acid not leſs than from 1.15 to 1.23, without reference to the common diſtinction of ſingle and double aquafortis.

When the ſpecific gravity of the acids is neglected, as is but too generally the caſe, theſe differences occaſion ſerious inconveniences in the uſe of ſolutions, whoſe properties often depend on the accuracy of their proportions, and on determinate degrees of ſaturation.

Secondly, from the impurity of the acids. The muriatic acid of commerce always contains iron and ſulphuric acid; if the former exiſt in any notable proportion, it is unfit for the ſolution of tin; the preſence of the latter is of leſs importance, though, on the whole, unfavourable to delicate colours. The nitrous acid varies conſiderably in its purity, being ſubject to greater or leſs admixture with the muriatic; the nitre it is made from being ſeldom free from marine ſalt. The aquafortis of commerce is, in fact, an aqua regia. This variation of the proportion of muriatic acid in the nitrous, is of the utmoſt importance, ſince the properties of the ſolution eminently depend upon this. With muriatic acid only, tin forms a colourleſs and permanent ſolution, one of whoſe diſtinguiſhing properties is, its ſtrong affinity or attraction for oxygen. With decoction of cochineal, it forms a deep and dull purple-coloured precipitate, which, however, gradually abſorbs oxygen, and becomes crimſon, eſpecially when expoſed on the filtre. With decoctions of Brazil and peachwood, it affords crimſon precipitates, varying in intenſity with their ſaturation with tin. It decompoſes all the combinations of iron with colouring matter, deoxygenating the iron which it carries off, leaving the tin in combination with the colouring matter. Thus a madder black becomes a red on the application of muriate of tin. On this property is founded the art of printing on dyed grounds, of which we ſhall treat hereafter. With nitrous acid, unleſs very dilate, tin contracts a very feeble union, and is generally precipitated as ſoon as diſſolved, in a ſtate fully ſaturated with oxygen. The addition of a ſmall quantity of muriatic acid renders this ſolution more permanent, provided it be not fully ſaturated with tin, and the addition of larger portions approximates the ſolution ſtill more to the nature of the former, and renders it capable of ſupporting a greater degree of ſaturation. The properties of the ſolution depend greatly on the proportion of muriatic acid, and conſequently of muriate of tin contained in it. When ſmall, the precipitate with cochineal is bright carmine ſcarlet. It does not decompoſe the combinations of iron with colouring matter, unleſs the ſolution be far from ſaturation, and this effect is then due to the diſengaged acid only.

The purity of the tin is another requiſite which ſhould be carefully attended to. The fine tin of Cornwall, commonly called grain tin, ſhould be employed. If alloyed with lead, it is wholly unfit for theſe purpoſes.

In lieu of muriatic acid, ſal ammoniac and common ſalt are oftentimes employed to form an aqua regia with nitrous acid. The ſolution differs little from that formed by a mixture of the two acids, the allowance being made by the portion neutralized by the alkali of the neutral ſalt.

From this ſhort outline of the hiſtory of the ſubſtances employed in the formation of the ſolutions of tin, and of the properties of the ſolutions themſelves, may be deduced ſuch general ideas as will elucidate and explain many anomalous effects in their combinations with different colouring matters, and ſeem to direct future experiment in the diſcovery of thoſe minute, but often important, conditions neceſſary to the formation of particular ſhades of colour.

The following examples of ſpirit reds, as they are improperly called by calico printers, will illuſtrate ſome of the preceding obſervations, and may be conſidered as ſpecimens of the moſt beautiful and brilliant colours it is poſſible to form upon cotton.

1. Prepare an equa regia by diſſolving two oz. of ſal ammoniac in one pound of nitrous acid of ſpecific gravity 1.25. To this add two ounces of fine grain tin; decant it carefully off the ſediment, and dilute it with $\frac{1}{4}$ its weight of pure or diſtilled water.

To one gallon of water add one pound of cochineal, ground as fine as flour; boil half an hour; then add two ounces of finely pulverized gum dragon, and two ounces of cream of tartar, and ſtir till the whole is diſſolved. When the liquor is cool, add one meaſure of the preceding ſolution of tin, to two of the cochineal liquor, and incorporate well by ſtirring. Apply this with the pencil or block, ſuffer it to remain in the cloth ſix or eight hours, then rinſe off in ſpring water. This colour will be a bright and beautiful ſcarlet.

2. Boil 12 pounds of Brazil chips during an hour in as much water as will cover them. Draw off the decoction, and pour on freſh water, and boil as before. Add the two liquors together, and evaporate ſlowly down to one gallon. To the decoction whilſt warm add four ounces of ſal ammoniac, and as much gum dragon or ſenegal as will thicken it for the work required. When cool, add one of the ſolution of tin before deſcribed, to four, ſix, or eight of the Brazil liquor, according to the colour wanted. Suffer it to remain from 18 to 24 hours on the cloth, then rinſe off in ſpring water as before. The colour will be a pale and delicate pink. If it is required deeper, the decoction muſt be made ſtronger, and uſed in the proportion of three or four to one of the ſolution of tin. Nicaragua or peachwood, though not ſo rich in colouring matter as Brazil, yields a colour, however, which is, if poſſible, more delicate and beautiful. The fine pinks produced by certain houſes, which have for years been the envy and admiration of the trade, are afforded by this fine dye-wood.

Theſe colours require no liming, ſimple affuſion with water being ſufficient to precipitate the colouring matter in combination with the tin. The theory of theſe mixtures is the ſame as the preceding. They require, however, a greater exceſs of acid to hold the colouring matter in ſolution. A decoction of cochineal poured into a ſaturated ſolution of tin, occaſions an inſtant precipitate which is not rediſſolved, and the greater part of which, if applied to cloth, would come off in the operation of rinſing. It is ſometimes neceſſary to add a ſmall quantity of muriatic acid to prevent this precipitation, or to correct it when it happens, and ſal ammoniac is ſuppoſed to have the ſame effect, probably by engaging the water of the ſolution.

With the aluminous ſalts, the decoction of cochineal and Brazil forms colours leſs brilliant than thoſe we have juſt deſcribed, but which are applicable in caſes where the exceſs of acid in the ſolutions of tin is attended with inconvenience.

1. To one gallon of water, add eight ounces of finely ground cochineal, and two ounces of bruiſed galls; boil half an hour, ſtrain the liquor whilſt hot through a fine cloth, upon four ounces of cream of tartar and four ounces of gum, and thicken with gum dragon. This colour requires liming.

2. Upon 6lbs. of Brazil and 2 oz. of galls, pour one gallon of water, let them ſoak ſome time, then boil two hours, replacing the evaporated liquor with freſh water. Strain through a fine cloth upon 4lb. of gum ſenegal, and add one pint of the acetite of alumine, deſcribed in a former part of this article.

The addition of galls in the two preceding formulæ is ſuppoſed to import ſolidity to the colours in ſome way analogous to the operation of galling in ſilk and cotton dyeing, of which we ſhall have occaſion to ſpeak hereafter. Their conſtitution is otherwiſe the ſame as the berry and bark yellows, and moſt others of this claſs of colours.

Purple.

1. If the ſolution of tin directed for the pink in the laſt article be mixed with ſix times its bulk of a decoction of logwood poured whilſt hot upon four ounces of ſal ammoniac, and $2\frac{1}{2}$ lbs. gum ſenegal, a bright and lively purple will be obtained, the hue of which varies with the ſtrength of the decoction and the proportion of ſolution of tin employed.

2. If inſtead of the ſolution of tin, the acetite of alumine before alluded to, be uſed in various proportions of one ſixth, eighth, &c. purples differing in ſhade and intenſity will be formed, applicable in ſome caſes, but poſſeſſing leſs ſolidity than moſt of the colours already deſcribed.

The conſtitution of theſe compounds is the ſame as the preceding.

Olive.

Olives are variouſly compounded, according to the colour required.

1. By mixing chemical black in various proportions with berry or bark yellow. The depth and fulneſs of the olive depends on the quantity of black.

2. By a decoction of logwood added in greater or leſs quantity to the bark or berry yellow.

3. By the addition of copperas or nitrate of iron to decoctions of yellow or aſtringent colouring matters, ſuch as bark, ſumac berries, weld, &c. each of theſe produces a different hue, varying from the green olive to a drab or cloth colour. By mixing theſe decoctions in different proportions, and by varying their ſtrength, and the quantities of copperas

or nitrate of iron added to each, a multiplicity of ſhades may be produced, of which it is impoſſible to convey any preciſe or definite ideas.

Theſe colours may be indifferently thickened with flour or gum, as beſt ſuits the work required, but when nitrate of iron is added to ſolutions containing gum, the inſtant coagulation that takes place muſt be counteracted by the addition of a portion of free nitrous acid. This effect ariſes from the ſtrong action exerted by metallic oxyds, at the maximum of oxydation, on mucilage or gum. When the decoction is very concentrated, and contains ſufficient colouring matter to engage the whole of the iron, this effect takes place in a leſs degree, but with ſolutions adapted to the production of the foregoing colours, a coagulation invariably takes place, unleſs counteracted by the preſence of a portion of free acid. Of this action of metallic oxyds on the ſolution of gum we ſhall further treat under the article Gum.

Claſs III.

In this claſs, the colouring matter is ſimply held in ſolutions, by an acid or alkali, and in that ſtate applied to the cloth without the intervention of any mordant.

The moſt important of theſe colours, is the alkaline ſolution of indigo which forms the topical or.

Pencil Blue.

1. Prepared ſolution of pot-aſh, by boiling together 7½lbs. of quick lime, and 15lbs. of pot-aſh, in 10 gallons of water. Decant off the clear liquor, and ſeparate the remainder from the lime by means of the filter. To one gallon of this ſolution, add 1lb. of red arſenic, or orpiment, and 1lb. of fine indigo, both previouſly ground together in a mill with ſufficient water to form a thick paſte. Bring them up gradually to a boil, ſtirring carefully all the time, and then withdraw the fire. Thicken the ſolution with the beſt gum ſenegal, and for the pale ſhades of blue, dilute with one, two, &c. meaſures of gum-water.

The quantities and relative proportions of pot-aſh, orpiment, and indigo in a gallon of pencil blue vary conſiderably with different calico printers, and within certain limits, it appears, that the accuracy of theſe proportions is not of great importance. Hauſman, an intelligent French printer, employs 15lbs. of pot-aſh, 6lbs. of orpiment, and 8lbs. of indigo, to 12 gallons of water; and Oberkampf, proprietor of the celebrated manufactory of Tony, a ſtill greater proportion of indigo. Some printers add brown ſugar, and Bancroft has propoſed to ſubſtitute this for the orpiment, but without ſucceſs.

The ſolution, when recently made, is a yellowiſh green, but by expoſure to air, becomes gradually deeper, and at laſt blue. In this ſtate, it is wholly unfit for uſe, it contracts no union with the cloth, and is detached from it in the firſt operation of rinſing.

Of the peculiar nature and properties of indigo, we ſhall have occaſion to treat hereafter, under its proper head, at preſent it will ſuffice to obſerve, that it owes its colour and inſolubility in alkalies, to a portion of oxygen intimately combined with it. To render it ſoluble, therefore, it muſt be deprived of this oxygen, by the action of a ſubſtance having a more powerful affinity for it, and the ſulphuret of arſenic, or orpiment, is uſed for this purpoſe. Sulphate of iron, has a ſtrong affinity for oxygen, and is employed in de-oxygenating indigo for certain purpoſes; but the oxyd of iron not being ſoluble in alkalies, the ſolutions of indigo, formed by it, become quickly regenerated by the abſorption of oxygen, and cannot even be transferred from one veſſel to another. The ſulphuret of arſenic, on the contrary being very ſoluble in alkalies, preſents the double advantage of de-oxygenating the indigo, and of retaining it awhile in that ſtate, till on its application to cloth, it becomes expoſed ſo completely to the action of atmoſpheric air, as to regain its oxygen, colour, and inſolubility; and becomes fixed in its original or blue ſtate.

The copper coloured pellicles, which forms on the ſurface of pencil blue, and is renewed immediately on its removal, ariſes from the abſorption of oxygen, which, in ſpite of the action of the orpiment, is continually taking place. Hence ariſes that diſpoſition to unevenneſs, which is the great diſadvantage of this blue; the unavoidable expoſure to air of ſmall portions of the colour during its application with the pencil, reviving greater or leſs portions of indigo, and conſiderably reducing its ſtrength.

Moſt calico printers boil up the quicklime with the other ingredients, thinking its preſence not leſs neceſſary than the pot-aſh and orpiment; by this means a conſiderable portion of the ſolution of indigo is taken up by the ſediment, which careful waſhing does not wholly ſeparate. As the action of the lime is confined merely to the alkali, which it renders cauſtic, and capable of acting with greater force on the other ingredients; it is certainly much more economical to render the pot-aſh cauſtic before its addition to the indigo. A conſiderable waſte of colour is by this means prevented, and the ſolution may be thickened the moment the ebullition has ceaſed without waiting for the depoſition, which in the old mode takes place.

Orange.

The oxyd of iron, when diſſolved in acetous acid, forms one of the moſt uſeful and important mordants, as we have already ſhewn in the former part of this article. It is alſo capable of imparting a very pleaſing and permanent colour itſelf to cotton, when applied in ſolutions of tolerable ſtrength and purity, and forms the orange, buff, and gold colour of the calico printers.

1. The ſolutions of iron in vinegar, ſtrengthened by the addition of copperas may be uſed, but the pureſt and brighteſt gold colours are obtained from copperas and ſugar of lead, in the proportion of 5lbs. of the former, and 1lb. of the latter, to a gallon of water. When thickened with gum, and employed undiluted, it affords, when limed, a full ſtrong gold colour, and with two, four, ſix, &c. times its bulk of water, various ſhades of orange and buff, which reſiſt the action of air, alkalis, and ſoap; and are rather exalted than impaired by frequent waſhing. The addition of ſugar of lead, is to increaſe the ſtrength of the ſolution. A gallon of water diſſolves about 4lbs. of copperas. The addition of a pound of ſugar of lead, enables it to take up another pound nearly, and the ſtrength of the ſolution may be ſtill further increaſed by equal additions of the two ſalts. The operation of liming is a ſimple precipitation of the oxyd of iron on the cloth, and in caſes when this cannot be performed, the proportion of ſugar of lead muſt be increaſed to nearly that of the copperas. It is only the paler ſhades of orange, however, which are to be obtained this way. The deep gold colour before named, is not to be procured without the aid of a precipitant. Spaniſh brown is ſometimes added to a ſolution of iron, and employed in ſuch a caſe, but it contracts no union with the cloth, and is readily removed by ſimple waſhing and beating. When the orange, or gold colour, is thickened with flour, a ſmall portion of nitrate of iron muſt be added to the paſte, for reaſons we have aſſigned on a former occaſion.

2. A beautiful, but fugitive orange, is obtained by boil-

ing half a pound of annotta with 1lb. of cauſtic pot-aſh in a gallon of water, and thickening the liquor with gum. This colour acts powerfully on the ſieves and blocks, which it very ſoon deſtroys, and on this account, and alſo from its want of permanence is ſeldom uſed. It may either be ſimply rinſed off, or firſt paſſed through water rendered ſlightly acidulous with ſulphuric acid, or what is ſtill better through alum-water. This operation is the very reverſe of liming, for here the colouring matter to be precipitated, being held in ſolution by an alkali, an acid muſt be employed for that purpoſe. The colour by this means is conſiderably heightened, and when applied with the pencil, is uſeful in ſome caſes where the other colours will ſupport the action of alum-water without injury.

Borax, and even ſpirits of wine, are ſometimes added to the alkaline ſolution of annotta, and are ſuppoſed to contribute to its ſtrength and fixity, though on what principle it is not eaſy to diſcover.

Green.

The oxyd of copper, diſſolved in volatile alkali, affords a pale and delicate green, which is ſometimes employed intermixed with other colours. Turnings of copper, or verdigriſe, which is more generally uſed, may be digeſted in a low heat with ſpirits of ſal-ammoniac. Care muſt be taken that the heat be very moderate, and the veſſel in which the ſolution is made, well ſtopped, the ammoniac will otherwiſe be driven off, and loſt. When the alkali has taken up as much copper as it can diſſolve, the ſolution muſt be thickened with gum, and applied with the block or pencil. In a few days the ammoniac evaporates and leaves the oxyd of copper on the cloth, which muſt be rinſed to free it from the gum and ſuperfluous colour.

The blues produced by alternate immerſion in copperas and lime, and alſo in the ſolution of indigo, by the ſame ſubſtances, properly come under this claſs of colour, as they are ſolutions of colouring matter in lime and alkalis. As the proceſſes by which they are applied, differ however very materially from all thoſe that we have been treating of, they claim a ſeparate and diſtinct notice. For the details of theſe operations, and the mode of preparing the paſtes for bark and pale blue dipping, and the colours for China blue, we muſt therefore refer our readers to the article *Dipping* Blue.

Colours, in *Dyeing*.—There are five ſimple, primary, or mother colours, uſed by the dyers: from the mixture whereof all the other colours are formed; theſe are blue, red, yellow, black, and brown colour; each of which ſee under their proper head, Blue, Red, &c.

Of theſe colours, mixed and combined, other colours are formed, which are infinitely various, according to the proportion of the different ingredients that are employed, or the proceſſes by which they are blended. Thus a mixture of *blue* and *yellow* forms *green*, which is diſtinguiſhed by dyers into a variety of ſhades, according to the depth of the ſhade, or the prevalence of either of the component parts. Hence we have *ſea-green*, *graſs-green*, *pea green*, &c. &c. *Blue* and *red* form different ſhades of *violet*, *purple*, and *lilac*. A mixture of *yellow* and *red* produces *orange*. Mixtures of *black* with other colours conſtitute *greys*, *drabs*, and *browns*. For a more particular account of theſe and other colours; and the method of procuring and applying them; ſee the article Dyeing. See alſo the preceding article.

The greateſt perfection in the art of colours would be to find the means of preparing the fineſt colours without the uſe either of acid or alkaline ſalts, which uſually ſubject the colours to change, or elſe are apt to prey upon the cloth, canvas, &c. as we ſee in verdigriſe, the blue and green cryſtals of copper, &c. It appears highly probable, that the Indians, for making the fine bright and durable colours, wherewith their chintzes and callicos are ſtained, make uſe of metalline ſolutions; for ſome ſtained callicos, brought from thence, having been kept 40 or 50 years, the bright colours have been obſerved to eat out the cloth, exactly in the ſame manner as acid ſpirits, which diſſolve metals, are found to do.

Since theſe, then, are the inconveniences attending ſuch colours, we ought to ſearch for menſtruums with which to extract colours, which are neither acid nor alkaline; and for ſuch metalline oxyds, precipitates, or powders, as will not loſe their colours, by being well waſhed to get out their ſalts; to prepare certain metalline matters, by mere calcination, or the bare aſſiſtance of fire; and laſtly, to look out for native colours, wherein no ſaline matter abounds.

Mr. Geoffroy has given a very curious proceſs for making two clear, ſpirituous, inflammable liquors, which differ very little in taſte and ſmell, and being mixt together give a fine carnation colour, without any ſenſible fermentation.

To make the firſt of theſe liquors, put a ſmall handful of dried red roſes into a glaſs bottle; pour on them rectified ſpirit of wine, till it covers them an inch; let this ſtand in a cold infuſion four or five hours; then pour off the liquor, which will be clear and colourleſs, as when put on. The ſecond liquor is made by dropping into rectified ſpirit of wine, ſo much oil of ſulphur, by the bell, or ſpirit of vitriol, as will be borne in it without giving it any very ſenſible acidity when taſted. When theſe liquors are thus prepared, let a ſmall quantity of the latter be dropped into ſome of the former, and the whole will become of a fine carnation colour, though there is no fermentation, nor any other change perceived in it, but barely that of colour. If inſtead of this laſt liquor, there be added to the firſt a few drops of the ſpirit of ſal ammoniac, the whole will become green.

Make a ſlight infuſion of galls in water, ſo as not to colour the water; make alſo a weak ſolution of green vitriol in water, ſo that it may appear colourleſs; mix theſe two colourleſs liquors together, and an inky blackneſs is immediately produced; add to this black liquor a little oil of vitriol, and the liquor becomes pellucid and colourleſs again; then add to this a little ſalt of tartar, and the whole is black again.

Put a little bruiſed camphor into rectified clear oil of vitriol; ſhake the mixture, and it will become black, and the camphor will be diſſolved; add to this a little water, and the liquor becomes clear, and the camphor is found ſeparated at top, in its own form, and native whiteneſs.

Infuſe lignum nephriticum in cold water, and pour off the clear liquor. This held up againſt the light, appears of a fine yellow, but viewed from the light, of a beautiful blue: a little ſpirit of nitre put to this liquor makes it loſe the power of reflecting the blue rays, and a little oil of tartar, afterwards added, recovers that power again.

Logwood, infuſed in water, gives a red colour. Put to this a little ſpirit of urine, and it becomes of a fine purple; and drop in afterwards a little ſpirit of ſalt, and it becomes of a pale red.

A beautiful blue tincture may be made from filings of copper, by digeſting them in ſpirit of urine, hartſhorn, or the like. The addition of oil of vitriol deſtroys the blue colour; and a little ſpirit of ſalt turns it green.

Pellucid oil of vitriol, mixed with pellucid oil of turpentine, produces a thick red balſam. And common oil, mixed with fair water, by means of a little wax, and continued rubbing, turns into a thick white balſam, called cold cream.

Oil of vitriol, diſtilled from quickſilver, leaves a white powder behind, which, if water be poured on it, becomes yellow.

Diſſolve quickſilver in ſpirit of nitre, and to part of it add ſpirit of urine, and a white powder is precipitated; to another part of the ſolution add oil of tartar, and a yellow powder falls to the bottom.

Dip a new pen in ſpirit of vitriol, and write with it on common blue paper, and the letters will appear red.

A pellucid ſolution of ſaccharum ſaturni being written with on paper, becomes inviſible when dried; but the bare fumes of an infuſion of quick lime, and orpiment, in water, will render the inviſible writing black and legible.

Volatile ſalt of ſal ammoniac, which is white, mixed with cryſtals of copper, which are green, produce a fine purple.

The original and ſimple, as well as the mixt, colours are producible by mixture. Thus, if the ſun's rays paſs through two pieces of glaſs, the one blue, and the other yellow, and be afterwards received upon a white paper, the colour there ſeen is green. The dyers make cloth blue with woad, and then turn it green by the yellow herb called luteola, or dyers' weed. To a yellow ſolution of gold in aqua regia add a blue one of copper in ſpirit of urine, and the mixture becomes green. The painters every day practiſe this art of producing new colours by mixture.

Metalline and mineral matters are reducible to a conſiderable degree of ſubtlety, or ſmallneſs of parts by fire, or dry calcination, ſo as to leave them durably poſſeſſed of their native or adventitious colours. Thus lapis lazuli, by being calcined, becomes the fine rich blue called ultramarine; light ochre, by the ſame treatment, becomes a light red, or fleſh colour, the moſt uſeful fleſh-colour in painting. Lead, by calcination, becomes durably red, and iron durably brown; but a proper method ſeems wanting for the dry calcinations of the nobler metals, gold and ſilver; though, for the uſes of gilding, theſe are eaſily prepared by dipping linen rags in their reſpective ſolutions, and then drying, and burning them to aſhes, whereby a dry and fine metalline powder is procured.

Colour, in *Heraldry*, the heraldic colours are nine, and were anciently expreſſed by the word *tincture*, *viz.* or, argent, azure, gules, ſable, vert, purpure, tenney, and ſanguine, and alſo by precious ſtones and planets; the armorial colours are blazoned in different terms, according to the rank and dignity of the perſon whoſe arms are deſcribed, as follows:

Colours.	For Commoners by Tinctures.	For Peers by Precious Stones.	For Emperors, Kings, and Princes, by Planets.
Yellow,	Or,	Topaz,	Sol.
White,	Argent,	Pearl,	Luna.
Blue,	Azure,	Sapphire,	Jupiter.
Red,	Gules,	Ruby,	Mars.
Black,	Sable,	Diamond,	Saturn.
Green,	Vert,	Emerald,	Venus.
Purple,	Purpure,	Amethyſt,	Mercury.
Orange,	Tenney,	Jacinth,	Dragon's head.
Dark red,	Sanguine,	Sardonix,	Dragon's tail.

For a fuller account of each, ſee under the reſpective heads.

Or, and argent are metals, and it is an invariable rule in heraldry not to put colour upon colour, or metal on metal; that is if the field be of a colour, the charge or bearing muſt be of a metal.

Colour, in *Law*, is a probable or plauſible plea; though in reality falſe at bottom; and only calculated to draw the trial of the cauſe from the jury to the judge: and, therefore colour ought to be matter of law, or doubtful to the jury.

In pleading it is a rule, that no man be allowed to plead, ſpecially, ſuch a plea as amounts only to the general iſſue; but in ſuch caſe he ſhall be driven to plead the general iſſue in terms, by which the whole queſtion is referred to a jury. But if a defendant in an aſſiſe or action of treſpaſs, be deſirous to refer the validity of his title to the court rather than to the jury, he may ſtate his title ſpecially, and at the ſame time *give colour* to the plaintiff, or ſuppoſe him to have an appearance or colour of title, bad indeed in point of law, but of which the jury are not competent judges. As if his own true title be that he claims by feoffment, with livery from *A.* by force of which he entered on the lands in queſtion, he cannot plead this by itſelf, as this plea amounts to no more than the general iſſue. But, he may allege this ſpecially, provided he goes farther and ſays, that the plaintiff claiming by *colour* of a prior deed of feoffment, without livery, entered, upon whom he entered; and may then refer himſelf to the judgment of the court, which of the two titles is the beſt in point of law. (Doctor and Student. 2. c. 53.) Every *colour* ought to have the following qualities. 1. It is to be doubtful to the *lay-gens*, as in caſe of a deed of feoffment pleaded, and it is a doubt whether the land paſſeth by the feoffment, without livery or not. 2. *Colour* ought to have continuance though it wants effect. 3. It ſhould be ſuch *colour*, that, if it were effectual, would maintain the nature of the action, as in aſſiſe, to find colour of freehold, &c. (10 Rep. 88, 90, and 91.) *Colour* muſt be ſuch a thing, which is a good colour of title, and yet it is not any title. (Cro. Jac. 122.) If a man juſtifies his entry for ſuch a cauſe as binds the plaintiff or his heirs for ever, he ſhall not give any *colour*; but if he pleads a deſcent in bar, he muſt give *colour*, becauſe this binds the poſſeſſion, and not the right; ſo that when the matter of the plea bars the plaintiff of his right, no *colour* muſt be given. When the defendant entitles himſelf by the plaintiff; where a perſon pleads to the writ or to the action of the trial; he who juſtifies for titles; or where the defendant juſtifies as ſervant; in all theſe caſes no *colour* ought to be given. (10 Rep. 91. Lutw. 1343) Where the defendant doth not make a ſpecial title to himſelf, or any other, he ought to give *colour* to the plaintiff. (Cro. Eliz. 76.) In treſpaſs for taking and carrying away twenty loads of wood, &c. the defendant ſays, that *A. B.* was poſſeſſed of them, *ut de bonis propriis*, and that the plaintiff claiming them by *colour* of a deed after made, took them, and the defendant retook them; and adjudged that the *colour* given to the plaintiff makes a good title to him, and confeſſeth the intereſt in him. (1 Lil. Abr. 275.)

Thus, e. gr. in an action of treſpaſs for taking away the plaintiffs beaſts, the defendant urges, that before the plaintiff had any intereſt in them, he himſelf was poſſeſſed of them, as his proper goods; and delivered them to *A. B.* to deliver to him again, when, &c. and *A. B.* gave them to the plaintiff: and the plaintiff, ſuppoſing the property to be in *A. B.* at the time of the gift, took them, and the defendant took them again from the plaintiff; whereupon the plaintiff brings his action.—This is a good *colour*, and even a good plea. Doct. and Stud.

Colour *of office*, is when ſome unjuſt action is done under countenance of office or authority. See BRIBERY and EXTORTION.

To Colour *ſtrangers goods*, is when a free man allows a foreigner to enter goods at the cuſtom-houſe in his name.

Colours, *camp*, are a ſort of ſmall colours planted on the right and left of the parade of a regiment when in the field. They are about 18 inches ſquare, and of the colour of the facing of the regiment, with the number of the regiment marked on them. The poles, to which they are fixed, ſhould be about 7 feet 6 inches long; except thoſe of the quarter and rear guards, which ought to be about 9 feet long.

Colours, *field*. See Field.

Colours, *guard*. See Guard.

Colours *uſed in the drawings of fortifications and military works*, are chiefly *Indian ink*, *carmine*, *verdigriſe*, *ſap green*, *gum bouch*, *Pruſſian blue*, *Indigo*, *ſmalt*, *ultramarine*, *umber*, *gum-water*, which articles ſee ſeparately, as well as the article Fortification.

Colours, *Colores*, in the *Ancient Muſic*, was uſed to ſignify the muſical ſpecies belonging to a genus.

In this ſenſe the *chromatic genus* was ſaid to have three *colours*; and the *diatonic* two. The *enharmonic*, having no ſubordinate ſpecies, had but one *colour*. Hence the ancients reckoned three *genera*, and ſix *colours*, in muſic; that is, ſo many different diviſions of the *diateſſaron*, or fourth.

Colours, *diatonic*, or *muſical ſcale of*.—In the courſe of ſir Iſaac Newton's experiments on the properties of light, (Optics, book i. part ii. prop. 3.), he diſcovered the remarkable fact, that the ſpectrum of the ſun's image, formed by refracted light, let into a darkened room, is longitudinally divided by the points ſeparating the different colours, *viz.* violet, indigo, blue, green, yellow, orange, and red, into ſpaces which are reſpectively equal to $\frac{1}{9}$, $\frac{1}{18}$, $\frac{1}{12}$, $\frac{1}{12}$, $\frac{1}{15}$, $\frac{3}{80}$, and $\frac{1}{16}$, parts of the double length of the ſpectrum, as, ſuppoſe the ſpectrum to be 360 parts in length, then $\frac{80}{720}$, $\frac{40}{720}$, $\frac{60}{720}$, $\frac{60}{720}$, $\frac{48}{720}$, $\frac{27}{720}$, and $\frac{45}{720}$, will repreſent the length of each colour reſpectively, and adding theſe ſucceſſively in the reverſe order, to $\frac{360}{720}$, we have $\frac{405}{720}$, $\frac{432}{720}$, $\frac{480}{720}$, $\frac{540}{720}$, $\frac{600}{720}$, $\frac{640}{720}$, and $\frac{720}{720}$, which, in their loweſt terms, are $\frac{1}{2}$, $\frac{9}{16}$, $\frac{3}{5}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{5}{6}$, $\frac{8}{9}$, and 1, and appear to be the diatonic ratios anſwering to the *octave*, minor *ſeventh*, major *ſixth*, *fifth*, minor *fourth*, minor *third*, major *ſecond*, and *key*-note; or, to VIII, 7th, VI, V, 4th, 3d, II, and key, repreſented in the gamut by *c*, bB, A, G, F, bE, D and C.

From the experiments of Henry Brougham, jun. eſq. Philoſophical Tranſactions, 1796, it appears, that not only by *refraction*, but by *inflection*, *deflection*, and *reflection*, the rays of light may be ſeparated on a chart or ſcreen: and he mentions numerous experiments, wherein the limits of the ſeveral colours on the ſpectrum were carefully marked with the point of a needle, after which the papers thus marked were put away, and a freſh paper ſubſtituted for other experiments: the meaſurement or compariſon of the lengths of the intervals occupied by each colour on the different papers, being purpoſely deferred, until the whole courſe of experiments was completed, in order to prevent any preconceived opinions from operating, in making the experiments: the reſults are repreſented as agreeing, in the ſpaces $\frac{1}{9}$, $\frac{1}{18}$, $\frac{1}{12}$, $\frac{1}{12}$, $\frac{1}{15}$, $\frac{3}{80}$, and $\frac{1}{16}$, occupied by the violet, indigo, blue, green, yellow, orange, and red colours, being the very ſame, as to arrangement, as thoſe by refraction above-mentioned.

It is obſervable, that the notes compoſing the octave thus produced, do not anſwer to the major-key of bB as it might ſeem to do, although ſome writers on muſical intervals have aſſerted, that nature produces only the major-key or diviſion of the octave, and that the minor *third* bE or $\frac{5}{6}$ is nowhere to be found in nature. If we were to conſider the *colorific ratios* $\frac{1}{2}$, $\frac{9}{16}$, $\frac{3}{5}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{5}{6}$, $\frac{8}{9}$, and 1, found above as a minor octave, and to belong to the notes in the gamut *a*, G, F, E, D, C, B and A; and find the ratios anſwering to the octaves of C and B, *viz.* $\frac{5}{12}$, and $\frac{4}{9}$, or *c* and *b*; then, if from each of the above ratios we deduct the ratio $\frac{5}{6}$ (or multiply by $\frac{6}{5}$), we obtain $\frac{1}{2}$, $\frac{8}{15}$, $\frac{3}{5}$, $\frac{27}{40}$, $\frac{18}{25}$, $\frac{4}{5}$, $\frac{9}{10}$, and 1, for the notes in the octave *c*, *b*, *a*, G, F, E, D, and C, but which is not a major diatonic octave, becauſe thoſe principal notes, the V and 4th, or G and F, have not the ratio of $\frac{2}{3}$ and $\frac{3}{4}$ as they ought to have. Thus we ſee, that the eight notes anſwering to a colorific minor-key, do not hold the proper relation between themſelves, for forming a major-key, by merely aſſuming the third of the firſt key, as the new key-note: and ſtrictly ſpeaking, the ſame may be obſerved of any other tranſpoſition or modulation whatever, upon eight diatonic notes, or even upon any 12 notes compoſing an octave, taking all the conchords into account; although moſt of the keyed inſtruments, as organs, harpſichords, &c. in uſe, are made and played upon, and the notation or writing of muſic itſelf is founded upon this ſuppoſition, which is far from being correct.

Colour, in *Painting*, is applied both to the drugs, and to the teints produced by thoſe drugs, variouſly mixed and applied.

The principal colours uſed by painters, are red and white lead or ceruſs; yellow and red ochres; ſeveral kinds of earth, as umber, &c. beſides orpiment, black lead, cinnabar, gamboge, lake, bice, verditer, indigo, vermillion, verdegris, ivory black, biſtre, lamp black, ſmalt, ultramarine, and carmine; each of which, with the manner of preparing them, their uſes, &c. ſee under their reſpective heads.

Of theſe colours, ſome are uſed ground in oil, others only in freſco, others in water, and others only for miniature.

Colours, in an *Eccleſiaſtical Senſe*, are uſed both in the Latin and Greek churches, to diſtinguiſh ſeveral myſteries and feaſts celebrated therein.

In the Latin church are only regularly admitted five colours, viz. *white*, *red*, *green*, *violet*, and *black*: the *white* is for the myſteries of our Saviour, the feaſts of the Virgin, thoſe of the angels, ſaints, and confeſſors; the *red* for the myſteries and ſolemnities of the holy ſacrament, the feaſts of the apoſtles and martyrs; the *green* for the time between Pentecoſt and Advent, and from Epiphany to Septuageſima; *violet* in Advent, Chriſtmas, in vigils, rogations, and in votive maſſes in time of war: laſtly, *black* for the dead, and the ceremonies thereto belonging. Cloths of gold and ſilver, and embroidery, ſerve indifferently for all ſolemnities.

In the Greek church the uſe of *colours* is almoſt obliterated, as well as among us: *red*, among them, was the *colour* for Chriſtmas, and the dead, as black is ſtill for the laſt among us.

Colours, *Accidental*. See Accidental.

Colours, *Local*. See Local.

Colour, *rings of*. See Rings.

Colours, *water*. See Water.

COLOURABLE *title*. See Title.

COLOURING, in *Painting*, one of the great component and eſſential parts of painting, is the art of giving to every object in a picture its true and proper hue, as it appears under all the various circumſtances or combinations of light, middle-tint, and ſhadow; and of ſo blending and contraſting the colours, as to make each appear with the greateſt advantage and beauty, at the ſame time that it contributes to the richneſs, the brilliancy, and the harmony of the whole.

It likewiſe poſſeſſes powers which, when judiciouſly applied, render it highly conducive to the character and expreſſion of the ſubject repreſented.

A noble author, lord Lanſdown, "ſays, that verſification is in poetry, what colouring is in painting, beautiful ornament;" but the compariſon is ill-founded. Verſification is, indeed, an ornament, and ſo is colouring; but the former is merely an ornament, whereas the latter is neceſſary to the painter to enable him to make his imitation or repreſentation complete. "Should the moſt able maſter in deſign," ſays Mr. Webbe, "attempt by that alone a roſe or grape, we ſhould have but a faint and imperfect image; let him add to each its proper colours, we no longer doubt, we ſmell the roſe, we touch the grape."

Colouring, like chiaro-ſcuro, may therefore be divided into kinds; that which is *neceſſary* for rendering the imitation juſt and intelligible, and that which is *expedient* or *ornamental*, as contributing to make the work at once more impreſſive to the imagination, and more harmonious and delightful to the eye. Truth in the local tints is alone required in the firſt kind; the ſecond demands choice in their ſelection and diſtribution. For illuſtration, let us ſuppoſe the principal figure in a piece to be dreſt in ſky-blue, and another figure near it, of leſs conſequence in the ſtory, to be repreſented in ſcarlet, with an under veſtment of bright yellow, and let the light be made to ſtrike equally on both: in ſuch a caſe, it would be utterly impoſſible to give an effect agreeable or harmonious to the picture; although each of theſe objects ſhould be painted with the utmoſt exactneſs and truth; nay, the combination, though found in nature itſelf, would excite feelings of diſguſt and averſion; whereas, if the principal figure were dreſſed in ſcarlet and white draperies, and the figure next it in blue of not too light or bold a tint, the effect would be harmonious and pleaſing; and another point of great importance would be gained, as the eye would then be attracted by the principal figure, which could not have been the caſe in the former inſtance, where the gaudy combination of yellow and red muſt infallibly, as is natural with all warm colours, have firſt obtruded itſelf into notice. However, as the eye has the ſame intuitive abhorrence of unharmonious combinations of colours, that the ear has of diſcordant ſounds; it is, therefore, not ſurpriſing if we ſo ſeldom meet with enormities like the one above ſuppoſed, even in the works of thoſe artiſts who leaſt of all can lay claim to the ſcientific arrangement of colours: to produce effects not unharmonious, or diſagreeable, requires no great exertion of talent; but to perform all that can be done by the moſt ſkilful application of the various powers of the art is the lot of few.

In treating of chiaro-ſcuro, we have obſerved, that the part of it to which we have given the appellation of neceſſary or natural chiaro-ſcuro, was in a greater or leſs degree underſtood and practiſed from the earlieſt period of the reſtoration of painting: the ſame was the caſe with reſpect to what we have termed neceſſary colouring, or truth in the local tints.

The oldeſt painters of Florence, Giotto, Buffalmacco, and others; and ſtill more ſo, Simone Memmi, Ambrogio Lorenzetti, and the reſt of Saneſe ſchool of the ſame period, made frequently not unſucceſsful attempts at truth and even beauty in the tints of the fleſh and other parts of their pictures; and ſometimes produced a diſtribution of colours by no means ungracious in the whole; though the prodigal uſe of gold grounds and gold ornaments bid defiance to an effect truly harmonious. Mapolino da Panicale, Maſaccio, Dominico Ghirlandajo, and Pietro Perugino, went much further, and we rarely find a want of delicacy of colouring in the parts of their pictures, or of harmony in the general effect. But ſtill this was the reſult of a happy natural feeling for what was beautiful rather than of an approved and well-founded theory. It was not till the period when Leonardo da Vinci laid the foundation of an improved ſyſtem of chiaro-ſcuro, that the Bellini's of Venice began to diſcover the beautiful effects reſulting from a ſkilful combination or oppoſition of colours, at the ſame time that they attained a richneſs and truth in their local tints, far exceeding any thing hitherto practiſed. In both theſe qualities, however, they were ſoon far ſurpaſſed by their ſcholars, Georgione da Caſtel Franco, and Titiano Vecelli, who, ſuperadding to the moſt aſtoniſhing richneſs of colour, the powerful light and ſhade of da Vinci, produced works which, in their way, have baffled all future attempts at improvement. The tone of colour of their pictures is not that of nature in her every day garb; it is ideal, like the chiaro-ſcuro of Coreggio or Rubens; that which may be ſuppoſed, but which, perhaps, is ſeldom or ever found in nature: the depth and mellowneſs of their tints can ſcarcely be accounted for but by the ſuppoſition of a tranquil but vigorous light ſhining through the heated atmoſphere of a ſummers evening. The world was aſtoniſhed at this new ſtyle, and it is no wiſe ſurpriſing that Tintoretto, Paolo Veroneſe, and others who followed, being unable to do better, ſhould attempt ſomething different; the manly, the ſober ſenatorial dignity of Giorgione and Titian, was changed for magnificence, for ſhow, for glitter, and for ornament; invention, compoſition, deſign, and expreſſion, were all made ſubſervient to the inordinate deſire of effect of colour; the ſubject of the work could in many inſtances with difficulty be diſcovered, and their pictures may, in moſt caſes, be compared to bewitching nonſenſe uttered by the ſilver tongue of the woman we love; to the ſweet but fatal ſong of the Syren. There ſeems to be nothing in the colouring of Giorgione and Titian, incompatible with the greateſt purity of deſign, ſublimity of compoſition, or propriety of expreſſion; but the ſplendid extravagances, the caded ſtuffs, the gaudy trappings of the more modern Venetians, are wholly inconſiſtent with true grandeur, and too frequently ſeem to reſemble the wretched effort of poverty to perſonate opulence, or the deſpicable attempt of the lacquey or courtezan to outvie by their tinſel apparel the dignity of the nobleman, or the ſimple elegance of the woman of diſtinction.

Whilſt the two great founders of the Venetian ſchool enraptured the ſight by their tranſcendent and novel effects of colour, the Roman and Florentine painters, though principally applying their talents to the attainment of ſtill higher objects, were not wholly unmindful of this part of the art. Many of the freſcos of Raffaelle in the ſtanzas of the Vatican, and in particular the diſpute of the ſacrament, the St. Peter delivered out of priſon, the maſs of Bolſena, and the Heliodorus, are ſeverally coloured with the richneſs of Venetian tint, or with the pearly hue of Parma. However, from the latter works of this great maſter, it ſhould appear that he did not at all times conſider this branch of painting as worthy his attentive regard. Fra. Bartolommeo di San Marco, in his madonnas and apoſtolic figures, united grandeur of deſign and breadth of chiaro-ſcuro to a tone of colour at once dignified, tranquil, and harmonious; and Andrea del Sarto, except in ſome of his laſt works, where he in ſome degree adopted the gay and frivolous ſtyle then beginning to be in vogue, painted with a ſtrength and ſobriety of tint every way adapted to give increaſed intereſt and expreſſion to the devotional or ſacred ſubjects which he generally treated.

At this period, as if nature then made holiday, and was prodigally laviſh of her gifts, the great Coreggio appeared, and by his aſtoniſhing freſcos in the cupolas, and other works at Parma, ſeemed to caſt a new radiance on the world of art. In him the very ſoul of harmony reſided, and the magic of his pictures ſo irreſiſtibly intrances the ſight, as to render us almoſt incapable of diſcriminating, whether the aſtoniſhing effect is moſt the reſult of the breadth and ſoftneſs of his chiaro-ſcuro, or the beautiful combinations and tranſitions of his colours. However, delicacy of tint ſeems to have been the aim of Coreggio; richneſs and luxuriance of colour that of the Venetians. And it has been obſerved of the great artiſt of Parma, that the fleſh in his pictures ſeems generally of too firm a texture, and to want that humid appearance, the reſult of inſenſible tranſpiration, which forms one of the particular characteriſtics of human bodies, and which Titian and Giorgione ſucceeded ſo admirably in repreſenting.

Theſe are the great maſters of colouring amongſt the Italians. After this period a corrupt and frivolous ſtyle for ſome time predominated, and more particularly in the Roman and Florentine ſchools of painting. With them it was not uncommon to ſee yellow draperies ſhaded with purple, red ones with blue, or green with ſome other tint; as if it had been the intention to repreſent changeable ſtuffs; and the eye ſeemed gradually to have become accuſtomed to the moſt unharmonious, the moſt gaudy and abſurd combinations. Baroccio indeed made an effort to ſtem the torrent of this daſtard taſte. After having aſſiduouſly ſtudied the works of Coreggio, he attempted to adopt his principle, and ſo far ſucceeded, that he deſervedly had, and ſtill has his admirers. But in the works of Baroccio, the red, the blue, and the yellow are too oſtentatiouſly diſplayed, and want blending; which ſeems to juſtify the ſame critique on them that was made upon the works of Parrhaſius, that his figures looked as if they had fed on roſes.

The Venetian painters it is true, never entirely loſt ſight of the genuine principles of colouring; but even in this reſpect they fell far ſhort of the great founders of their ſchool above-mentioned, and the general frivolity of their taſte, too frequently occaſions even their merits to be paſſed by unregarded.

Coreggio had few followers; his divine ſpirit found not, like that of Donatello, a kindred place of abode amongſt his ſucceſſors; nevertheleſs, the Lombards preſerved a certain richneſs and harmony of tint, which ſtill, in this particular, entitled them to a higher rank than their contemporaries of lower Italy. The Carracci, towards the latter part of the 16th century, reſcued the art from the degeneracy into which it had fallen; and by uniting, as far as they were able, the different beauties of the Roman, Florentine, Lombard, and Venetian ſchools, produced a new ſtyle, and gave their name to an academy eminent for the various talents which it called forth. Their colouring, however, is not ſo rich as the Venetian, nor ſo harmonious as that of Coreggio; but it is exempt from glaring defect, ſimple and tranquil, and well ſuited to the ſobriety and dignity of hiſtory painting.

Of Caravaggio, their rival at Rome, it was hyperbolically ſaid, that he dipt his pencil in fleſh itſelf: but we have to regret that the black and opaque ſhadows which pervade his pictures, probably occaſioned in ſome degree by the periſhable nature of ſome colours which he uſed, deſtroy much of that truth of effect, which, from the praiſes beſtowed on him in his life-time, we have grounds for ſuppoſing they originally poſſeſſed.

The pencil of Guercino is broad, and his tints freſh and vigorous, but his effect is generally more the reſult of chiaro-ſcuro than of any remarkably ſkilful arrangement of his colours.

The pictures of Guido, in his firſt manner, poſſeſs conſiderable force of tint; but he afterwards abandoned this ſtyle for a mode of colouring weak and inſipid: nevertheleſs, his grace, his knowledge of expreſſion, and his unparalleled freedom of pencilling, gained him innumerable followers; till at length, that which ought to have been conſidered one of his greateſt faults, was numbered amongſt his beauties. It is true, that ſhortly after this period, landſcape was carried to the higheſt pitch of perfection by the Pouſſins, Salvator Roſa, and Claude Lorraine; the former giving to their pictures a ſtyle of colouring at once ſolemn and impreſſive, the latter a truth of aerial tint, never before or ſince attained. Nevertheleſs, a ſlight and flimſy manner of colouring became one of the characteriſtics of the Italian ſchools, and the deſerted daughter of Iris ſought an aſylum in the leſs congenial climes of Flanders and Holland.

Amongſt the Flemiſh painters, Rubens undoubtedly holds the firſt place; and his works, as ſir Joſhua Reynolds obſerves, "have that peculiar property always attendant on genius, to attract attention, and enforce admiration, in ſpite of all their faults." This, however, is not the place for a *general* inquiry into his merits. With reſpect to his colouring, we have to obſerve, that it evinces that exuberance and boldneſs of genius, which in every other part of the art peculiarly characteriſes him. It poſſeſſes neither the ſober richneſs of Titian, nor the delicate harmony of Coreggio, but ſeems frequently, by the gorgeous aſſemblage of tints, to vie with the gaiety of the chaplet or noſegay. It is perhaps, however, a matter worthy of inveſtigation, whether the great variety of colours, introduced by Rubens in the draperies and other parts of his pictures, has not, by the too great equality of their diſtribution, upon ſome occaſions proved detrimental, rather than advantageous, to the richneſs and ſplendour of effect, which at all times ſeems to have been his principal object; and whether that object would not have been more effectually attained, had he followed the practice of the early Venetians, in giving to two or three colours a more decided pre-eminence.

The ſtyle of Vandyke is more pure and chaſte. The modeſt tenderneſs of his tints gently but irreſiſtibly perſuade; and his numerous portraits, by their delicacy and truth of expreſſion, ſtill captivate and intereſt the beholder, even where the perſonages they repreſent have been long buried in oblivion.

Rembrandt is, as Mr. Fuſeli obſerves, a genius of the firſt claſs in every thing which relates not to form; but though as a colouriſt he certainly holds a pre-eminent rank, the effect of his pictures is, perhaps, as we have ſaid of Guercino, more the conſequence of his aſtoniſhing chiaro-ſcuro, than of the freſhneſs and vigour of his tints. His works preſent not the gorgeous combinations of colour found in thoſe of Rubens, or that humid mellowneſs of tint in the fleſh, ſo much admired in the pictures of Titian and Giorgione; nevertheleſs, they evince a moſt powerful conception of harmony, a beautiful gradation of tint, and great ſolemnity of tone. His lights have a brilliancy peculiarly his own; ſcarcely more owing to the powerful oppoſition of his chiaro-ſcuro, than to the extraordinary method which he uſed of painting the luminous parts of his pictures with a very great body of colour in almoſt a dry ſtate; whilſt his broad maſſes of ſhadow poſſeſs a magic tranſparency, making as it were darkneſs viſible.

It would be endleſs to enumerate the many admirable colouriſts of Flanders and Holland, who ſucceſſively trod the footſteps of the great artiſts above-mentioned: indeed, there are few painters of thoſe ſchools whoſe works may not be ſtudied with advantage as to this part of the art; the richneſs and harmony of their tints, the beauty and ſtrength of their chiaro-ſcuro, and the delicacy of their pencilling, compriſing their chief excellence. Sir Joſhua Reynolds, the great colouriſt of the laſt century, fully appreciated their merits; and by combining ſomewhat of their principle with the different ſtyles of Titian and Coreggio, has ſucceeded in producing, in not a few inſtances, a richneſs and brilliancy of colour, inferior, perhaps, to neither, and, at the ſame time, different from all. Happy for his reputation, if from an inſatiable deſire of ſurpaſſing, he had not, in ſo many of his pictures, indulged himſelf in the uſe of colours and varniſhes, which, like the more delicate bloſſoms of nature, are the earlieſt ſubject to decay.

We have been the more diffuſe in our attempt to characteriſe the principal maſters eminent for colouring, as we are aware that ſo little can be ſaid upon the preceptive part of this branch of art, which, more peculiarly than any other, ſeems to depend upon the delicacy and perfection of the organs of viſion, and the nice diſcriminations of feeling and judgment. The great artiſt laſt-mentioned was perhaps the only colouriſt who ever wrote upon colouring, and we ſhall therefore have recourſe to the aſſiſtance of his admirable diſcourſes, in our attempt to give ſome idea of the leading principles of this part of the art.

It has already been obſerved, that chiaro-ſcuro may exiſt in the greateſt perfection, independently of colours; but colouring, without the aid of lights and ſhadows, would preſent us nothing more than the geographical chart or the harlequin's coat; and the ſtudy of it muſt therefore neceſſarily imply ſome previous knowledge of chiaro-ſcuro.

In the commencement of this article we have, for the ſake of diſtinction, divided colouring into two kinds; the *neceſſary*, and the *expedient* or *ornamental:* the *neceſſary* that which denotes truth in the local tints of the objects repreſented; the *expedient* or *ornamental*, that upon which the diſtribution of the parts, and the harmony of the whole, depends. Although it might, upon firſt conſideration, appear difficult to ſay, which of theſe two kinds or diviſions of colouring requires the greateſt exertion of talent; yet there ſeems little doubt but that examples of a very high degree of truth in the local tints in pictures, are more rarely met with than an equal meaſure of beauty in the general arrangement of the colours. To this truth of local tint, therefore, the utmoſt effort of the artiſt ſhould be directed: nature will be his beſt guide, and next to her the works of Giorgione, Titian, and Giacomo Baſſano in figures, and thoſe of Claude and ſome of the Dutch ſchool in landſcape, and the other inferior departments of painting.

That ſpecies or diviſion of colouring, which we have termed the *expedient* or *ornamental*, is of a very extended range, and may be compared to rhetoric which gives additional luſtre to truth, and enables the orator, even where proof is wanting, to ſupport his argument upon ſpecious though fallacious grounds. By a judicious oppoſition of one colour to another, the ſkilful painter is enabled to give to each an increaſed delicacy or an additional ſplendour; and by the ſame means a colour may be made to appear different from that which it really is; and thus a ſemblance of truth in the local tint may be frequently attained, even where that truth is in reality very far from exiſting. If the tint of the fleſh be of too warm a hue, a yellow drapery placed next it, reſtores it to harmony; if too red, a crimſon or a ſcarlet mantle takes away or diminiſhes the imperfection; if it appear cold, blue or purple oppoſed to it gives it a proportionable degree of warmth: and thus by contraſting one colour with another, the painter is enabled to give to each the degree of value he deſires, according as his ſubject and the general effect of his work requires. It was the cuſtom of Rubens, when he wiſhed to give brilliancy to the principal figures in his picture, to oppoſe to the fleſh, a map of ſcarlet drapery, and another of pure white; by theſe means the tints of the naked parts acquired wonderful air of truth, at the ſame time that a ſplendid and harmonious effect was produced.

The balance of cold and warm colours in a picture ſeems to bear a ſtrong affinity to the gradation or contraſt of the chiaro-ſcuro, and demands equal attention. "A certain quantity of cold colours," ſays ſir Joſhua Reynolds, "is neceſſary to give value and luſtre to the warm colours;" he adds, "that the maſſes of light in a picture be always of a warm mellow colour, yellow, red, or a yellowiſh-white; and that the blue, the grey, or the green colours be kept almoſt entirely out of theſe maſſes, and be uſed only to ſupport and ſet off theſe warm colours; and for this purpoſe a ſmall proportion of cold colours will be ſufficient." "Let this conduct be reverſed;" continues this excellent writer, "let the light be cold, and the ſurrounding colours warm, as we often ſee in the works of the Roman and Florentine painters, and it will be out of the power of art, even in the hands of Rubens or Titian to make a picture ſplendid and harmonious. The illuminated parts of objects are in nature of a warmer tint than thoſe that are in the ſhade: what I have recommended therefore is no more than that the ſame conduct be obſerved in the whole, which is acknowledged to be neceſſary in every individual part. It is preſenting to the eye the ſame effect as that which it has been accuſtomed to feel, which in this caſe, as in every other, will always produce beauty; no principle therefore in our art can be more certain, or is derived from a higher ſource."

We have treated of the doctrine of reflections in our obſervations on chiaro-ſcuro; (ſee CLAIR, *Obſcure*) it is proper, however, in this place to obſerve, that the body which receives a reflected light, receives, together with that light, ſomewhat of the colour of the object which gives the reflection; and this, in proportion to the ſtrength of light on the body reflecting, and the vicinity of ſuch body to that receiving the reflection. The ſkilful management of reflections is ſo indiſpenſible a part of colouring, that it cannot employ too great a ſhare of the ſtudent's attention: an excellent inſight into the principles of it will be afforded him by the works of Rubens and Jordaens; not perhaps the leſs ſo from theſe maſters having marked the reflections in their pictures with a preciſion and diſtinctneſs, perhaps even beyond what is warranted by the appearances of nature herſelf.

With reſpect to the application of colouring, it ſhould always be remembered, that like the other parts of the art, it is of a nature powerfully to contribute to the ſentiment and expreſſion of a picture; when the ſtyle adopted is in ſtrict conformity with the character of the ſubject repreſented. This conformity is therefore the firſt thing to be conſidered. If the ſubject is awful or melancholy, a grave ſombre tone of colour will be appropriate; if gay or magnificent, the moſt brilliant and gorgeous tints may be freely uſed. The dark hue given by Michelagnolo Buonaroti to his celebrated group in the boat, in the laſt judgment, with the cold light behind it, renders it perhaps not leſs a maſterpiece of colour, than the Venus and Adonis of Titian, or the ſleeping Nymphs of Rubens.

The following remarks of the author before cited ſeem highly applicable to the preſent purpoſe. "To give a general air of grandeur at firſt view, all trifling or artful play of little lights, or an attention to a variety of tints is to be avoided; a quietneſs and ſimplicity muſt reign over the whole work; to which a breadth of uniform and ſimple colour will very much contribute. Grandeur of effect is produced by two different ways, which ſeem entirely oppoſed to each other. One is, by reducing the colours to little more than chiaro-ſcuro, which was often the practice of the Bolognian ſchools; and the other, by making the colours very diſtinct and forcible, ſuch as we ſee in thoſe of Rome and Florence; but ſtill the preſiding principle of both thoſe manners is ſimplicity. Certainly nothing can be more ſimple than monotony; and the diſtinct blue, red, and yellow colours which are ſeen in the draperies of the Roman and Florentine ſchools, though they have not that kind of harmony which is produced by a variety of broken and tranſparent colours, have that effect of grandeur which was intended. Perhaps theſe diſtinct colours ſtrike the mind more forcibly, from their not being any great union between them; as martial muſic, which is intended to rouſe the nobler paſſions, has its effect from the ſudden and ſtrongly marked tranſitions from one note to another, which that ſtyle of muſic requires; whilſt in that which is intended to move the ſofter paſſions, the notes imperceptibly melt into one another."

It is not our intention here to detail the various modes adopted by artiſts in mixing their colours and varniſhes, or the modes of preparing the different kinds of grounds uſed for painting on. Every ſchool, and, more or leſs, every individual differs in his practice from another; and works of ſo high a claſs have been produced by each of theſe different methods, that we muſt conclude them all to be right, when rightly applied. However, in one point, the beſt colouriſts ſeem to agree, that the light parts of a picture ſhould be painted with a ſtrong body of colour, and the ſhadows with as much tranſparency as poſſible: and this is the more natural as well the eaſieſt mode of procedure, as all the light colours, and particularly white, are opaque; whereas all the dark colours are in a greater or leſs degree tranſparent.

COLOURING *of Spirits*. See SPIRITS.

COLPE, in *Ancient Geography*, a town of Aſia Minor, built, according to Pliny, in the place of *Archæopolis*.

COLPEDI, or COLPIDICI, a people of Thrace, who inhabited the environs of Ænos. Steph. Byz.

COLPISCIS, a name given by ſome to the *falx Venetorum*, or ſickle-fiſh, commonly called the marmot fiſh by the people of Venice. See FALX.

COLPODA, in *Zoology*, a genus of animalcules *(vermes infuſiora)* diſtinguiſhed by being of a ſimple form, pellucid, flat, and ſinuate.

Theſe worms are inviſible to the naked eye. They have been diſcovered and examined, chiefly by Müller, Adams, Joblot, and other curious writers, whoſe attention has been particularly devoted to microſcopical inveſtigations. Of the genus colpoda, ſeven ſpecies only appear to be deſcribed.

LAMELLA. Elongated, membranaceous, and bent on the anterior part.

This reſembles a long, narrow, pellucid membrane, which is narrower and obtuſe behind, curved towards the upper part, and has a ridge or fold paſſing through the middle. It is found in water, and when it moves is obſerved to proceed on the edge inſtead of flat ſurface. Found in common water.

ROSTRUM. Oblong, and hooked on the anterior part.

Diſcovered in water more pure than the former. The poſterior part of this ſpecies is obtuſe, and one of the edges from the top to the middle is dilated, thick, and apparently triangular.

MELEAGRIS. Changeable, with the anterior part hooked, and the poſterior folded up.

Lives in water impregnated with vegetables, and is of a variable form, the anterior part clear, the poſterior full of molecules, with the margin ſinuous.

CUCULLUS. Ovate, ventricoſe, with an inciſion beneath the tip.

Generally oval, and containing from eight to twenty-four bright molecules, the margin irregular. Common in a variety of vegetable infuſions.

REN. Thick, and ſinuate in the middle.

Deſcribed by Joblot, who diſcovered it in the infuſions of hay. The form is ſlightly kidney-ſhaped, of a yellow colour, opake, and filled with molecules.

PYRUM. Convex, oval, the tip produced into a beak.

The body is tranſparent, of a pale colour, and filled with molecules.

HIPPOCREPIS. Thick, narrow in the middle, ſemilunar, and greeniſh. Found in ſtagnant meadow water.

COLPUSA, in *Ancient Geography*, one of the ancient names of *Chalcedon*, according to Pliny.

COLSA, a town of Aſia, placed by Ptolemy in Armenia.

COLSIR, in *Geography*, a town of Aſia, in the country of Thibet; 50 miles N.E. of Harachar-Hotun.

COLT, in *Zoology*. See FOAL and HORSE.

COLT's-*foot*, in *Botany*. See TUSSILAGO *Farfara*.

COLT's-*foot, alpine*. See CACALIA *Petaſites*.

COLTHENA, in *Ancient Geography*, placed by Ptolemy near the Araxes, and N. of Soducena.

COLTIE, among the *Timber Merchants*, a word uſed to expreſs a tree which has a defect in ſome one of its annual circles, which renders it unfit for many of the uſes it might have been otherwiſe fit for. In this caſe ſome one of the annual circles near the centre is perceived by the eye to be thicker than the reſt, and its ſap veſſels larger. It has an appearance much different from that of the others, and is ſo looſely connected both to its inveſtient, and inveſted circles, that, on ſawing a tranſverſe piece of the trunk off, it will ſlip out from the others, and ſo leave the heart looſe, and the reſt hollow, ſeeming to have been only fitted, not connected, to the others. In ſplitting the wood for other uſes, it yet more readily drops out, and the timber of ſuch a tree is therefore much leſs fit for general uſe than that of others. It is not eaſy to ſay to what accident, in the growth of the tree, this is owing, but it ſeems probable that it expoſes the tree to other accidents; in particular Bobart ſeems to think, that among the trees which were ſplit by the hard froſt, in the year 1683, while other trees of the like ſizes and kinds eſcaped, this *coltineſs* might be the occaſion of the miſchief, as well as of their being wind-ſhaken, or lagged. Philoſ. Tranſ. N° 165.

COLUBÆ, in *Ancient Geography*, a people of India, placed by Ptolemy on the other ſide of the Ganges, and near to it.

COLUBER, in *Zoology*, a genus of ſerpents diſtinguiſhed by having plates on the belly, and ſcales on the under parts of the tail.

The ſpecies of this genus are numerous. Linnæus deſcribes, upon the teſtimony of various writers, above ninety; and that number even has been conſiderably augmented by naturaliſts ſince his time. The ſpecies differ greatly in ſize and habit; ſome, as the vipers having the head large, flattiſh, and ſemi-cordated, with the body and tail of a moderate length, or rather ſhort; while others, as the greater part of the harmleſs ſerpents, have ſmall heads, with the body and tail much longer in proportion. In ſome, excluſive of the uſual ſcales under the tail, are a few ſcuta or undivided lamellæ, either at the beginning or towards the tip of the tail. The beſt works on this tribe of reptiles are "Synopſis methodica animalium Quadrupedum et Serpentini generis," of Ray. "Synopſis Reptilium," &c. of Laurenti; and thoſe of Seba and Cateſby. The obſervations of Boddaert, "Specimen novæ methodi diſtinguendi Serpentia." Nov. Act. Acad. Nat. Cur.; and "Beſchreibungeiner Schlange," &c. of Wiegel. The papers of Mr. Ellis, and another by Dr. Gray in the Philoſophical Tranſactions, relative to venomous ſerpents, are alſo intereſting. Several of thoſe deſcribed by count La Cepede deſerve particular attention. Profeſſor Pallas mentions ſome new kinds obſerved in Ruſſia and Siberia; others are mentioned by Sparrman, and a number of the viper tribe occur in the "Hiſtory of the Indian Serpents," publiſhed by the late Dr. Ruſſell.

Linnæus conſidered the number of abdominal plates and ſcales under the tail as a characteriſtic diſtinction of the different ſpecies of this genus; ſuch, however, is the inconſiſtency of this criterion that, in deſcribing the ſame ſpecies, ſcarcely two writers agree. Characters taken from the number of thoſe plates and ſcales in the ſerpent tribe, like thoſe from the number of rays in the fins of fiſhes, are not to be relied upon. The colours are liable to ſome variation; but the peculiar form and diſpoſition of the ſpots, lines, and other markings, afford, in general, a character by which the different ſpecies may be diſtinguiſhed.

Species.

VIPERA. Somewhat ferruginous, ſpotted with brown; beneath whitiſh; tail ſhort and mucronated.

Abdominal ſcuta 118, ſubcaudal ſcales 22. Linn. Haſſelq. Act. Upſ. 1750. *Aſpis Cleopatrae*, Laurenti.

This is the common viper of Egypt. Haſſelquiſt, who appears to have firſt deſcribed the ſpecies with accuracy, informs us, that it is imported in conſiderable quantities every year to Venice for the uſe of the apothecaries. Its ſize is ſomewhat ſmaller than that of the common viper; the head not ſo flat on the top, but very protuberant on each ſide; ſnout very obtuſe. The body is thick towards the middle, and ſomewhat quadrangular, but thin, and cylindric towards the head and tail, which laſt is ſhort, ſlender, conical, and terminated by a ſlightly incurved horny point or tip. The ſcales on the upper parts are oval and carinated. Haſſelquiſt deſcribes this ſpecies as being about two ſpans in length, excluſive of the tail, which meaſures only an inch. This is ſuppoſed by ſome to be the aſp, by the bite of which the celebrated Cleopatra determined rather to die than ſubmit to be carried captive to Rome, to grace the triumph of Auguſtus. Mr. Bruce, on the contrary, conſiders the Ceraſtes to be the ſpecies employed on that momentous occaſion. Schneider is of opinion, that the Egyptian viper (C. vipera) muſt be the true *dipſas* of the ancients, a reptile which was popularly reported to kill by occaſioning the moſt exceſſive thirſt.

VARIEGATUS. Above cheſnut, variegated with grey and white; beneath, and on the ſides, pale yellow. *Aſpis variegata*, Laur. Amph. Seba, &c.

Conſidered as a native of America, and reſembles the laſt.

VENOSUS. Reddiſh aſh, with white tranſverſe veins; head long. *Aſpis cobella*, Laur. Amph. Seba.

A native of America, and is probably only a variety of C. vipera.

INTESTINALIS. Body equal, ſlender, with a lateral and longitudinal dorſal line, the laſt furcated near the eyes. Laur. Amph. Seba.

Inhabits Africa, and like the former is perhaps merely a variety of C. vipera.

BERUS. On the head a bilobate ſpot; body above cinereous (or reddiſh) with a black flexuous zig-zag ſtripe down the back, and belly purpliſh. *Coluber berus*, abdominal ſcuta 146, ſubcaudal ſcales 39. Linn. Fn. Suec. Amoen. Acad. 148—42. Weigel Abh. der Hall. 177—86. Scop. *Vipera.* Geſner Aldr.

This is the common Engliſh viper, and which is not only frequent in this country, but appears to be generally diffuſed over the reſt of Europe, and ſome parts of Aſia. If the varieties, deſcribed by Gmelin, are of the ſame ſpecies, it extends alſo as far as India. The var β of this author has the ſpots on the top of the head roundiſh, and ſomewhat confluent or running into a ſtripe; thoſe near the tail tranſverſe. This inhabits India. γ. Reddiſh with the head variegated; neck ſlender. A native of St. Euſtace. δ. The arch of the hind head intercepting a white ſpot. Inhabits India. ε. Spot on the head multipartite. Inhabits the Celebes. The whole of thoſe varieties are deſcribed and figured in the works of Seba.

Though the viper varies conſiderably in colour from a pale cinereous or yellowiſh ferruginous to deep or dull brown, the varieties agree in being marked with a continued ſeries of confluent rhomboid blackiſh ſpots, extending from the head to the tail. The head is broad, and ſomewhat flattened, and is more or leſs protuberant on each ſide at the back part; the front of the head is blackiſh, and on the upper part is a large divided and ſomewhat heart-ſhaped ſpot, the obtuſe diviſions of which are directed backwards; the lips are ſomewhat barred or variegated with black and light grey, and along each ſide of the body runs a row of roundiſh ſubtrigonal duſky ſpots, continuing to the end of the tail. The ſcales on the upper part of the body are carinated, the under parts of a blackiſh colour, with a blueiſh gloſs ſomewhat reſembling that of poliſhed ſteel. The general length of the viper is from eighteen inches to two feet, and it is affirmed by ſome writers to grow even to the length of three feet. The fangs of the viper, like thoſe of other poiſonous ſerpents, are ſituated on each ſide the fore part of the upper jaw, and are generally two in number, with a few ſmaller ones ſituated behind. The poiſon, as uſual, lies in a receptacle at the baſe of the fangs, and being perforated, when the animal bites, the compreſſion of thoſe receptacles forces out a drop of the poiſonous fluid, which paſſing through the aperture of the fangs is immediately inſtilled into the wound. The tongue is forked, and being ſoft and flexible is ſuſceptible of great extenſion: it may be perhaps ſuperfluous to add that this tongue is altogether incapable of inflicting any wound, or injecting poiſon, as ſome ancient writers credulouſly affirm; it may aſſiſt the animal in the capture of its inſect prey. The French naturaliſts are inclined to believe it is intended by nature to ſupply ſome defect of tranſpiration in the ſkin.

Hitherto the viper has been conſidered the moſt poiſonous of the European ſerpents, and many inſtances are recorded of the fatal effects reſulting from its bite. That the bite of this ſerpent is always productive of pain and temporary inflammation in the parts bitten is very evident; ſometimes alſo the ſymptoms may become alarming, or, in a few inſtances, through neglect or injudicious treatment of the wound, may even prove fatal; but upon the whole the bite of this creature does not appear pregnant with all thoſe dangers which the terrors and prejudices of the vulgar lead them to ſuppoſe. In England the bite of the viper is rarely attended with fatal conſequences. Fontana ſeems to doubt whether any well atteſted inſtance can be adduced of the viper having killed any perſon by its bite, even in the warm climate of Italy. The teſtimonies of authors, both as to the nature of the poiſon itſelf, and its effects on the animal frame are, however, confeſſedly at variance. According to Dr. Mead, and his aſſociates in the experiment, the poiſon of the viper, diluted with a little warm water, proved ſharp and fiery when taſted with the tip of the tongue, as if the tongue had been ſtruck through with ſomething ſcalding or burning. This ſenſation went off in two or three hours; but one gentleman, who would not be ſatisfied without trying a large drop undiluted, found his tongue ſwelled with a little inflammation; and the ſoreneſs laſted two days. On the contrary, abbé Fontana and ſome others deſcribe it as of no particular acrimony of taſte, but rather reſembling oil or gum, and Dr. Ruſſell, in his work on Indian ſerpents, affirms the ſame even of the poiſon of the cobra de capello. Boerhaave is of opinion that the poiſon of the viper may be taken into the ſtomach without danger, and quotes the caſe of Jacob Sozzi, who, at the court of the duke of Tuſcany, is ſaid to have ſwallowed three drams of this poiſon without experiencing any ill effects This poiſon, ſays Boerhaave, is rendered inactive by digeſtion in the ſtomach and bowels, ſo that it will not afterwards exert its ſad effects upon the blood; for a whole ounce of the venom taken by the mouth will not kill an animal, when, at the ſame time, a ſmall needle only, dipped in the ſame fluid, taking up perhaps no more than a hundredth part of a drop, and then thruſt into the blood of the living animal, almoſt infallibly kills. Fontana, on the contrary, affirms, that though the poiſon of the viper adminiſtered internally may not produce the ſame violent ſymptoms as the bite, that it cannot be taken with impunity. The opinion, pretty generally entertained among the ancients, ſeems to be in favour of the aſſertions of Boerhaave.

"The ſymptoms which follow the bite of the viper (according to Dr. Mead) when it faſtens either one or both its greater teeth or fangs in any part of the body, is an acute pain in the part wounded, with a ſwelling at firſt red, but afterwards livid, which, by degrees, ſpreads further to the neighbouring parts, and occaſions great faintneſs, and a quick, though low and ſometimes interrupted pulſe; great ſickneſs at the ſtomach, with bilious, convulſive vomitings, cold ſweats, and ſometimes pain about the navel; and if the cure be not ſpeedy, death itſelf, unleſs the ſtrength of nature prove ſufficient to overcome thoſe diſorders: and though it does, the ſwelling ſtill continues inflamed for ſome time; nay, in ſome caſes, more conſiderably upon the abating of the other ſymptoms than at the beginning; and often from the ſmall wound runs a ſanious liquor, and little puſtules are raiſed about it: the colour of the whole ſkin, in leſs than an hour, is changed yellow, as if the patient had the jaundice. Theſe miſchiefs (although different climates, ſeaſons of the year more or leſs hot, the greater or leſs rage of the viper, the animal itſelf being of a larger or ſmaller ſize, and conſequently able to communicate more or leſs venom, the wound made deeper, in a part more nervous or tendinous, and therefore receiving more of the poiſonous liquor, and the like circumſtances may variouſly heighten or abate them,) yet uſually diſcover themſelves much after the ſame manner in all; unleſs the bite happen not to be accompanied with the effuſion of that liquor, which is the main inſtrument and cauſe of this violent and ſhocking diſturbance." Dr. Mead cauſed ſeveral animals, as dogs, cats, and pigeons to be bitten by an enraged viper, which animals generally died, ſome in a longer and others in a ſhorter ſpace of time; but it was obſerved that, immediately after being bitten, they all exhibited ſigns of acute pain as if affected with ſickneſs, faintings, and convulſions. The venomous properties of the poiſonous fluid of the viper is not deſtroyed even by the death of the animal, as was proved by Dr. Mead; he took the head of a large viper that lay three hours after it was cut off, and was perfectly flaccid and without motion, and wounded a pigeon on the thigh by the fangs of the head; the bird preſently became convulſed, and died ſeven hours after. The Scythians, as Pliny relates, muſt have been aware that the poiſon of the viper would retain its venomous properties after being taken from the animal and dried, for they were accuſtomed to dip their arrows into its poiſon; this they previouſly prepared by mixing it with human blood.

From the following experiment it would ſeem that no very material difference takes place in the appearance of an animal killed by the bite of the viper, than if its death were occaſioned by any other caſe. To aſcertain this fact, a viper, being enraged by the members of the Tuſcan academy, and then ſuffered to bite the noſe of a ſtrong bull, the animal expired in a ſhort time, and being opened by the moſt expert anatomiſts, no uncommon alteration could be perceived either in the ſolid or fluid parts of the beaſt.

The viper, though ſo much dreaded on account of its bite has been very highly eſteemed both by the ancients and moderns as a reſtorative and ſtrengthening diet. The ancients uſed the fleſh of this ſnake in leprous and other caſes. The Greek phyſician Craterus, cured, as Porphyrius relates, a miſerable ſlave, whoſe ſkin, in a ſtrange manner, fell off from his bones, by adviſing him to feed on viper's fleſh in the manner of fiſh. Galen ſays, that thoſe afflicted with elephantiaſis are wonderfully relieved by eating viper's fleſh dreſſed like eels, and relates very remarkable cures of this diſeaſe performed by means of viper wine. In France and Italy, the broth, jelly, and fleſh of vipers is in much eſteem as a reſtorative medicine. In England we have to inſtance the well known circumſtance of ſir Kenelm Digby, who cauſed his wife lady Venetia to feed on capons fatted with vipers to recover her from a conſumption. According to Dr. Lewis, the dried fleſh of the vipers poſſeſſes none of the nutritious properties of the recent animal, and is totally inſignificant. A volatile ſalt was formerly drawn from vipers and ſold at a great price as a ſovereign remedy againſt the bites of vipers, and other poiſonous animals, but it is now found not to be materially different from the volatile alkaline ſalts procured by diſtilling other animal ſubſtances.

The viper abounds moſt in dry, ſtony, and chalky countries, or in the low herbage or underwood in thickets. It caſts its ſkin twice in the year, namely, in ſpring and autumn, and is ſaid to attain its full ſize at the age of ſix or ſeven years, but are capable of engendering when two or three years old. They copulate in May, and go about three months with young. "The viper (ſays Mr. White) is vivaparous, producing its young towards the cloſe of ſummer. On the 4th of Aug. 1755, we ſurprized a large female viper, which ſeemed very heavy and bloated as it lay on the graſs, baſking in the ſun. When we came to cut it up, we found that the abdomen was crouded with young, fifteen in number; the ſhorteſt of which meaſured full ſeven inches, and were about the ſize of full grown earth worms. This little fry iſſued into the world with the true viper ſpirit about them, ſhewing great alertneſs as ſoon as diſengaged from the belly of the dam: they twiſted and wriggled about, and ſet themſelves up, and gaped very wide, when touched with a ſtick, ſhewing manifeſt tokens of menace and defiance, though as yet they had no manner of fangs that we could find, even with the help of our glaſſes." In the month of May a female viper was opened, which had in it a chain of eleven eggs, about the ſize of thoſe of a black bird, but not ſo far advanced as to ſhew the rudiments of the young. Several intelligent folks (adds Mr. White) aſſure me that they have ſeen the viper open her mouth, and admit her helpleſs young down her throat on ſudden ſurprizes, juſt as the opoſſum does her brood into the pouch under her belly upon the like emergencies; and yet the London viper catchers inſiſt on it to Mr. Barrington that no ſuch thing ever happens.

Sir Thomas Brown ſeems inclined to believe this circumſtance: the young, he obſerves, ſuppoſed to break through the belly of the dam, will, upon any fright, for protection, run into it; for then the old one receives them into her mouth, which way, the fright being paſt, they will return again, which is a peculiar way of refuge, and although it ſeems ſtrange is avowed by frequent experience and undeniable teſtimony. The ſame is aſſerted by ſome other writers of no mean reſpectability.

The enemies of the viper are numerous, the herons in particular deſtroy vaſt numbers. Their prey conſiſts of frogs, toads, lizards, mice, and various ſmall quadrupeds. The viper is capable of ſupporting a very long abſtinence; it being known that ſome have been kept in a box without food for ſix months, and yet did not abate of their vivacity. They feed only for a ſhort period annually, and as a viper has been known to be a whole month devouring and digeſting a frog or toad, two ſuch meals would be ſufficient to ſupport it for a twelve month. It is remarked, that they never eat during confinement, for if mice, their favourite food be thrown into their box, though they will kill they never eat them. The violence of their poiſon decreaſes in proportion to the length of their confinement. Vipers, when at liberty, remain torpid throughout the winter, but when confined have never been known to take their annual repoſe. The beſt method of catching them is by putting a cleft ſtick on or near the head, then ſeizing them by the tail, and inſtantly dropping them into a bag. The viper catchers are frequently bit, but it is ſeldom the wound proves fatal: oil of olives, or ſalad oil, is ſaid to be the moſt effectual remedy. M. Sonnini ſeems fully ſatisfied of the efficacy of *eau de luce* as an antidote to the poiſon of vipers as well as other venomous ſerpents, the good effects of which he tells us he has experienced on ſeveral occaſions, and particularly at Guiana, where ſnakes are equally numerous and formidable. In his travels through Greece and Turkey, M. Sonnini mentions an inſtance of a child he ſaw at Sifour, three or four hours after it had been bitten by a vipour or venomous ſnake, in the ſmall of the leg. Both the leg and foot were much ſwelled, very hard, and of a blueiſh colour: the child ſuffered great pain, the wound no longer appeared, and the place was not diſtinguiſhed but by a larger ſwelling, and by pains more acute, which were occaſioned by touching it. He made the child ſwallow a few drops of *eau de luce* in half a glaſs of wine, and after ſome ſcarifications on the part bitten applied to it, a compreſs, ſteeped in this ſame water, which is known to be compoſed of volatile alkali and oil of amber. The reſult of this treatment was, that four hours after, the ſwelling was conſiderably diminiſhed; the child no longer felt any [illegible] and became tranquil; the compreſs of *eau de luce* was [illegible] renewed, and the child left in a fair ſtate for recovery. The ſame application is recommended by Sonnini in all [illegible]s; he obſerves, that the ſwelling of the wounded [illegible] ſpeedily diminiſhed, and the pain entirely removed by this means; but the *eau de luce* muſt be taken internally, according to this writer, as well as applied to the wound externally, in order to produce the deſired effect. The remedies which the Greeks commonly employ for curing the bite of ſnakes, as Sonnini affirms, conſiſt in cataplaſms of emollient plants, calculated to promote ſuppuration. Sow thiſtle is reckoned among them to poſſeſs, particularly, a ſpecific virtue againſt this ſort of venom. But this treatment, he adds, is very long; it frequently laſts two months, and never leſs than one; neither is it always ſucceſsful, and death pretty frequently carries off the patient from the torments which this mode of treatment cauſes him to ſuf[illegible].

PRESTER. Black, with deep black, dentated, dorſal line. *Coluber preſter*, abdominal ſcuta 152, ſubcaudal ſcales 32. Linn. Fn. Suec. 287. Lepech Itin. *Coluber vipera anglorum*, Laur. *Vipera anglica nigricans*, Petiv. Muſ.

This is the black viper of Engliſh authors, and which ſo completely reſembles the common viper in every particular, except the colour, that we are ſtrongly inclined to admit it as a mere variety of that ſpecies. The black viper of Auſtria appears from a ſeries of experiments made by Laurenti to be innoxious, ſince pigeons and chickens expoſed to its bite were no otherwiſe injured than by mere puncture without ſuffering any ſymptoms of poiſon, but it is not entirely certain that the kind deſcribed by Laurenti is of the ſame ſpecies as the black viper generally found in Europe, and which is almoſt univerſally allowed to be as poiſonous as the common viper.

Preſter inhabits the northern parts of Aſia as well as Europe.

CACODÆMON. Deep black; head broad and tumid; body thick. *Black viper*. Cateſby, Carol.

This kind is about the ſize of the common viper, but of a much thicker form, and entirely of a ruſty black colour; it is ſlow in its motions, and, when irritated, dilates the head, which is naturally large, to a ſurpriſing width, and threatening at the ſame time with a horrid hiſs; the fangs are large, and the animal is ſaid to be as dangerous as the rattle ſnake.

It is a native of Carolina, inhabiting chiefly the higher grounds.

CHERSEA. Duſky-bay, with black flexuous dorſal band, and the head oval, and whitiſh beneath. *Coluber cherſea*, abdominal ſcuta 150, ſubcaudal ſcales 34. Linn.

Inhabits the woody parts of Sweden, and is ſaid to be moſt frequent in the province of Smoland, where it is greatly dreaded by the inhabitants, who conſider its bite as mortal, unleſs the part bitten be immediately cut out. In the "Memoirs of the Swediſh Academy" is an account of a young man, a labourer, bit by this animal on the toe of the left foot. In the ſpace of ſix hours, the whole leg and thigh were red and ſwelled; the pulſe intermitted, and the patient was oppreſſed with pains in the head and bowels. The firſt day the patient drank a glaſs of the juice expreſſed from aſh-leaves mixed with wine every half hour, and had beſides a cataplaſm of the bruiſed leaves applied to the wound: in the evening alſo, he took a glaſs of warm olive oil. By theſe means the patient was greatly relieved, ſlept well during the night, and found the ſwelling much reduced by the next morning; but neglecting to repeat the remedies the firſt ſymptoms returned, and were again diſſipated by the ſame applications, and in two or three days the patient recovered. Linnæus attempted to cure a women wounded by the bite of a viper of this kind by means of olive oil, but his endeavours were unſucceſsful, and his patient died.

The *coluber cherſea* reſembles the common viper, but ſtill more the common aſp, though inferior in ſize, not often exceeding a ſpan in length. The colour is a duſky rufous brown, with a flexuous dorſal band of a deeper colour; the head ovate, of a pale colour, and marked with a heart-ſhaped duſky ſpot, the diviſions of which are directed backwards, and the body is round.

SCYTHA. Deep black above, beneath milk white, and poliſhed. *Coluber ſcytha*, abdominal ſcuta 153, ſubcaudal ſquamæ 31. Pallus It.

Inhabits woods in the mountainous parts of Siberia, where it was obſerved by Dr. Pallas. This ſpecies is not eſtemeed very poiſonous, and is of a ſmall ſize, ſeldom exceeding nine inches in length, or the thickneſs of a finger; the head is ſomewhat heart-ſhaped.

REDI. Head imbricated with very minute ſcales; body ferruginous, with a quadruple tranſverſe dorſal ſeries of ſhort brown ſtreaks. *Coluber redi*, abdominal ſcuta 152, ſubcaudal ſquamæ 33. Gmel. *Vipera franciſci redi*, Laur. *Otter*, Meyer Thiere.

Allied to the common viper, but eſteemed more poiſonous; it differs in being marked throughout the whole length of the upper parts, with a quadruple ſeries of ſhort, tranſverſe, alternate ſtreaks, of which the intermediate ones are often confluent. The colour of the underparts is rufous, eſpecially towards the head and tail. This kind is found in Auſtria and Italy near the ſea.

CERASTES. Sub-ferruginous, with brown tranſverſe ſpots, and horned eye-lids *Coluber ceraſtes*, abdominal ſcuta 150, ſubcaudal ſcales 25. Haſſelq. Act. Upſ. 1750. Linn. *Ceraſtes ex lybia*, Aldr. *Ceraſtes*, Bellon, Ellis Phil. Tranſ. *Ceraſtes*, Bruce's Travels Append. *La vipère céraſte*, La Cepède.

The ceraſtes viper grows to the length of eighteen inches or two feet, and is diſtinguiſhed by a pair of horns, or curved proceſſes ſituated above the eyes and pointing forwards; theſe horns have nothing analogous in their ſtructure to thoſe of quadrupeds, neither are they to be conſidered as weapons either offenſive or defenſive, but they contribute to give the animal an appearance of more than ordinary malignity. The ceraſtes is a native of many parts of Africa, and is found principally in ſandy deſerts and dry places. In Syria and Arabia it is particularly frequent, and is alſo found in many parts of Egypt.

The general colour of this ſnake is a pale yellowiſh or reddiſh brown, with darker ſpots diſpoſed at a diſtance from each other, and in a ſomewhat tranſverſe direction along the back, and near the ſides, the belly is blueiſh, or of a pale lead colour, and ſome writers ſay occaſionally almoſt white. In its manners the ceraſtes bears a very great affinity to the common viper, but is ſtill more to be dreaded than that ſpecies, as its bite is very dangerous, and the animal is ſaid to ſpring ſuddenly to a conſiderable diſtance, and aſſail without provocation thoſe who happen to approach it.

According to Mr. Bruce, the ceraſtes inhabits the greateſt part of the eaſtern continent, eſpecially the deſert ſandy part of it. It abounds in the three Arabias, and in Africa, I never ſaw (ſays Mr. Bruce) ſo many of them as in the Cyrenaicum, where the jerboa is frequent in proportion. He is a great lover of heat; for though the ſun was burning hot all day, when we made a fire at night, by digging a hole and burning wood to charcoal in it for dreſſing our victuals, it was ſeldom we had fewer than half a dozen of theſe vipers, who burnt themſelves to death by approaching the embers. The general ſize of the ceraſtes from the extremity of its ſnout to the end of the tail, Mr. Bruce tells us, is from thirteen to fourteen inches; in the Britiſh Muſeum, however, is a ſpecimen meaſuring rather more than two feet, and in that of Paris another ſtill larger. The head is triangular, very flat, but higher near where it joins the neck than towards the noſe. The length of its head, from the point of the noſe to the joining of the neck, is ten-twelfths of an inch, and the breadth nine-twelfths of an inch; between its horns is three-twelfths. The opening of its mouth, or rictus oris, is eight-twelfths; its horns in length three-twelfths; its large canine teeth ſomething more than three twelfths and a half; its neck at the joining of the head four-twelfths; the body, where thickeſt, ten-twelfths; its tail, at the joining of the body, two twelfths and a half; the tip of the tail one-twelfth; the length of the tail an inch and three-twelfths; the aperture of the eye two-twelfths, but this varies according to the impreſſion of light. The ceraſtes has ſixteen ſmall immoveable teeth, hollow, crooked, inwards, and of a remarkably fine poliſh, white in colour, inclining to blueiſh; nearly one-fourth of the bottom are ſtrongly fixed in the upper jaw, and folds back like a claſp knife, the point inclining inwards, and the greateſt part of the tooth is covered with a green ſoft membrane, not drawn tight, but, as it were wrinkled, over it, immediately above this, is a ſlit along the back of the tooth, which ends nearly in the middle of it, where the tooth curves inwardly. From this aperture, Mr. Bruce imagines, and not without reaſon, that the ceraſtes ſheds its poiſon, inſtead of from the point, where, with the beſt glaſſes he could never perceive an aperture; ſo that the tooth is not a tube, but hollow only half way; the point being calculated for making the inciſion, and by its preſſure occaſioning the venom in the bag at the bottom of the fang to riſe in the tooth, and ſpill itſelf through the ſlit into the wound. By this flat poſition of the tooth along the jaw, and its being defended by the membrane, it eats in perfect ſafety; for the tooth cannot preſs the bag of poiſon at the root, while it lies in this poſition, nor can it riſe in the tube to ſpill itſelf, nor can the tooth make any wound ſo as to receive it; but the animal is ſuppoſed to eat but ſeldom or only when it is with young. This viper has only one row of teeth. The poiſon is very copious for ſo ſmall a creature, being fully as much as a drop of laudanum dropped from a phial by a careful hand; it is of a yellow colour, and viewed through a glaſs is not perfectly tranſparent or pellucid.

During the day time the ceraſtes hides itſelf in the ſand, where it lives in dens ſimilar to thoſe inhabited by the jerboa. Mr. Bruce kept two of the ceraſtes in a glaſs jar, ſuch as is uſed for keeping ſweetmeats in, for the ſpace of two years, without having given them any food; they did not ſleep that he obſerved in winter, but caſt their ſkins the laſt days of April. The ceraſtes moves with great rapidity, and in all directions, forward, backward, and ſideways When he inclines to ſurpriſe any one, who is too far from him, he creeps with his ſide towards the perſon, and his head averted, till judging his diſtance, he turns round, ſprings upon him, and faſtens upon the part next to him. Mr. Bruce ſaw one of them in a houſe at Cairo crawl up the ſide of a box in which there were many, and there lie ſtill as if hiding himſelf,

ſelf, till one of the people who brought them to us, came near him, and though in a very diſadvantageous poſture, ſticking, as it were, perpendicular to the ſide of the box, he leaped near the diſtance of three feet, and faſtened between the man's fore-finger and thumb, ſo as to bring the blood. The man ſhewed no ſign of either pain or fear, and Mr. Bruce and his party kept him with them full four hours without his applying any ſort of remedy, or ſeeming inclined ſo to do. To make himſelf aſſured that the animal was in its perfect ſtate, Mr. Bruce make the man hold the ceraſtes by the neck, ſo as to force him to open his mouth, and lacerate the thigh of a pelican, a bird he had tamed as large as a ſwan. The bird died in about thirteen minutes, though it was apparently affected in about fifty ſeconds, and this even can ſcarce be conſidered as a fair trial, becauſe a few minutes before it had bit the man, and ſo diſcharged part of its virus, and it was made to ſcratch the pelican by force, without any irritation or action of its own.

It appears not only on the teſtimony of the above circumſtance, but on the relations of travellers in general of the greateſt reſpectability, that the natives of the countries infeſted by the ceraſtes, have a method of charming, or rather ſtupefying theſe and other ſerpents to prevent their biting, or to render their bite innoxious, however irritated the animal may be. Some pretend to poſſeſs preternatural powers over thoſe reptiles, while others ſay, they have certain preparations with which they anoint themſelves to obviate the fatal conſequences of their bite, and which is never ineffectually employed. Mr. Bruce ſpeaks at ſome length on this intereſting topic "a long diſſertation (ſays this writer,) would remain on the incantation of ſerpents. There is no doubt of its reality, the ſcriptures are full of it, all that have been in Egypt have ſeen as many different inſtances as they choſe. Some have doubted that it was a trick, and that the animals ſo handled, had been firſt trained and then diſarmed of their power of hurting; and, fond of their diſcovery, they have reſted themſelves upon it without experiment, in the face of all antiquity. But I will not heſitate to aver that I have ſeen at Cairo, (and this may be ſeen daily without trouble or expence) a man who came from above the catacombs, where the pits of the mummy birds are kept, who has taken a ceraſtes with his naked hand, from a tumber of others lying at the bottom of the tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breaſt and tied it about his neck like a necklace; after which it has been applied to a hen and bit it, which has died in a few minutes; and, to complete the experiment the man has taken it by the neck, and beginning at the tail has ate it as one would do a carrot, or ſtock of celery, without any ſeeming repugnance."

"We know from hiſtory, that where any country has been remarkably infeſted with ſerpents, there the people have been ſcreened by this ſecret. The Pſylli and Marmarides of old, undoubtedly were defended in this manner."

> "Ad quorum cantus mites jacuere caraſtæ."
> Sil. Ital. lib. iii.

"To leave ancient hiſtory, I can myſelf avouch, that all the black people in the kingdom of Sennaar, whether Fungee, or Nuba, are perfectly armed againſt the bite of either ſcorpion or viper. They take the ceraſtes in their hands at all times, put them in their boſoms, and throw them at one another, as children do apples or balls, without having irritated them by this uſage ſo much as to bite. The Arabs have this ſecret naturally, but from their infancy they acquire an exemption from the mortal conſequences attending the bite of theſe animals, by chewing a certain root and waſhing themſelves, (it is not anointing) with an infuſion of certain plants, in water. One day when I was ſitting with the brother of Shekh Adelan, prime-miniſter of Sennaar, a ſlave of his brought in a ceraſtes, which he had juſt taken out of a hole, and was uſing with every ſort of familiarity; I told him my ſuſpicion that the teeth had been drawn, but he aſſured me they were not, as did his maſter, Kitton, who took it from him, wound it round his arm, and, at my deſire, ordered the ſervant to carry it home with me. I took a chicken by the neck and made it flutter before him, his ſeeming indifference left him, and he bit it with ſigns of anger, the chicken died almoſt immediately;—I ſay his ſeeming indifference, for I conſtantly obſerved that however lively the viper was before, yet, upon being ſeized by any of theſe barbarians, he ſeemed as if taken with ſickneſs and feebleneſs, frequently ſhut his eyes, and never turned his mouth towards the arm of the perſon who held him. I aſked Kitton how they came to be exempted from this miſchief? He ſaid they were born ſo, and ſo ſaid the grave and reſpectable men among them. Many of the lighter and lower ſort talked of enchantments by words and by writing, but they all knew how to prepare any perſon by medicines, which were decoctions of herbs and roots. I have ſeen many thus armed for a ſeaſon, do pretty much the ſame feats as thoſe who poſſeſſed the exemption naturally; the drugs were given me, and I ſeveral times armed myſelf, as I thought, reſolved to try the experiment; but my heart always failed me when I came to the trial; becauſe, among thoſe wretched people. it was a pretence that they might very probably have ſheltered themſelves under that I was a Chriſtian, and that it had no effect upon me. I have ſtill remaining by me a ſmall quantity of this root, but never had an opportunity of trying the experiment."

Among the writers of antiquity we find abundant mention of the Pſylli, or ſerpent-eaters; men who pretended to poſſeſs the inherent power of charming ſerpents, and of devouring them without danger. Lucan ſpeaks of the practice of the Pſylli, or African tribes, and informs us they were employed by Cato to attend his expedition through the Lybian deſerts, for the recovery of his ſoldiers bitten by ſerpents. Strabo tells us the Pſylli, or men of Crene, poſſeſſed a ſecret antidote againſt the poiſon of thoſe reptiles. It appears equally certain that there are tribes of men in the Eaſt, who, to this day practiſe the ſame arts. Savary relates that when at Roſetta, he was preſent at the feſtival of Sidi Ibrahim, in which the rear of a proceſſion compoſed of the different trades, and cheiks, or prieſts of the country, bearing the ſtandard of Mahomet, was brought up by a troop of theſe modern Pſylli. Thoſe men, ſays Savary appeared frantic, with naked arms, their eyes wild, and enormous ſerpents in their hands, which twined round their bodies and endeavoured to eſcape. They ſeized the ſerpents forcibly by the neck, avoided their bite, and, regardleſs of their hiſſes, tore them with their teeth and eat them alive, while the blood ſtreamed from their defiled mouths; other Pſylli ſtruggled with them to free away their prey, for the contention was who ſhould devour a living ſerpent!—The aſtoniſhed populace followed, and cried—a miracle!

The remarks of Sonnini, one of the lateſt writers on this ſubject, may not prove unintereſting in concluſion. "The Eaſt, ſays he, was at all times the country of magicians: men boaſting to have the power of charming ſerpents, of braving their bite, and their venom, of rendering them docile to their voice; they formerly exiſted there under the name of Pſylli, and there are ſtill to be found, people who pretend to have inherited their ſecrets. I knew one of thoſe verſed in this kind of faſcination; he was certainly the moſt ignorant, and moſt fooliſh of the Greeks: his ſecret conſiſted chiefly in thirteen words, which it was neceſſary to pronounce in ſight of the ſerpents. He told me alſo, that, in order to guard againſt the bite of theſe reptiles, it was neceſſary to try to take one alive with the precaution of ſeizing it ſtrongly by the neck ſo as to prevent it from biting, and not to concern myſelf about the body and tail, the twiſtings of which lightly ſqueeze the arm. You muſt then ſlip round its neck a running knot made with coarſe thread, and draw it tight by degrees till the animal is ſtrangled. When it is on the point of dying, you open it and take out its fat, with which you rub your hands; then ſaid my modern Pſyllus to me, you have nothing more to fear from the bite of every ſpecies of ſerpent."

The figure of ceraſtes, occurs frequently among the hieroglyphic characters inſcribed upon remains of Egyptian antiquity.

Nasicornis. Somewhat olivaceous yellowiſh, variegated with black; flexuous, lateral band pale, and two horns on the ſnout. *Coluber naſicornis*, horn-noſe ſnake. Shaw Gen. Zool.

This remarkable ſnake was firſt deſcribed by Dr. Shaw in the Naturaliſt's Miſcellany. The moſt ſtriking peculiarity of his ſpecies are the two large ſharp pointed horns, ſituated on the top of the noſe, or anterior part of the upper jaw. Theſe horns ſtand nearly upright, but incline ſlightly backwards, and a little outwards on each ſide, and are of a ſubſtance ſomewhat flexible; their ſhape is rather triangular. The length of thoſe horns is about half an inch, and at the baſe of each ſtands an upright ſtrong ſcale, of nearly the ſame ſhape with the horn itſelf, and thus giving the appearance of a much ſmaller pair of horns. The mouth is furniſhed with extremely large and long fangs, or poiſonous teeth, two of which appear on each ſide of the mouth; the hinder pair being ſmaller. The length of this animal is about thirty-five inches. Its colour is yellowiſh, olive-brown, very thickly ſprinkled all over with minute blackiſh ſpecks. Along the whole length of the back, extends a ſeries of yellowiſh-brown oblong ſpots, or marks, each of which is imbedded in a patch of black; and on each ſide of the body from head to tail runs an acutely flexuous, or zig-zag line, or narrow band of an ochre colour, which is bounded beneath by a much deeper or blacker ſhade, than on the reſt of the body. The belly is a dull ochre colour or cinereous yellow, freckled with blackiſh ſpots and markings, and beſides theſe a number of black ſpots of various ſizes are ſparingly diſperſed over the whole animal; the tail is ſomewhat thin and ſhort in proportion to the body. The ſcales are hard, ſtiff and ſtrongly carinated, the head is covered with ſmall ſcales, and is marked on the upper-part by a longitudinal patch of brown, running out into pointed proceſſes at the ſides, and bounded by a ſpace of dull lead colour or cinereous. The ſhape of the head is broad and flattened, the cheeks varied with black and yellow marks. The horned ſnake is ſuppoſed to be a native of the interior parts of Africa. The ſpecimen above deſcribed, was obtained from the maſter of a Guinea veſſel by the Rev. Edward Charles Jenkins of Charleſtown in South Carolina.

Aspis. Noſe terminated by an erect wart; body rufous, with alternate, roundiſh, duſky, diſtinct, and confluent ſpots; beneath ſteel blue dotted with yellow. *Coluber aſpis*, abdominal ſcuta 146, ſubcaudal ſcales 46. Gmel. 146—34, Strom. Sondm. Col.—*Vipera moſis charas*. Laur. Amph. p. 100. n. 219.

Conſidered by ſome as a variety of coluber berus: it is a native of Dauphiny, Lyons, and Poitiers. Cepede deſcribes a ſnake that inhabits the northern parts of France under the name of L'Aſpic, but which, according to Latreille, is not the true coluber aſpis of Linnæus, as its name may imply. This kind, Cepede informs us, is about three feet in length, of which the tail meaſures three inches and eight lines. The head is rather large, and covered with ſmall carinated ſcales, the body larger, of ſimilar ſtructure, the colour, pale rufous grey, and along the upper parts are three longitudinal ranges, of roundiſh dark rufous ſpots, bordered with black, and which unite or become confluent near the tail, and thus exhibits the appearance of a zig-zag band, ſimilar to that of the common viper. The underparts of this ſnake, are of a duſky colour, marbled with dull yellow; its fangs reſemble thoſe of the common viper, and it is reputed equally poiſonous with that ſpecies. We introduce this ſnake under the ſpecies aſpis, conceiving it may be hereafter aſcertained to be of the ſame individual ſpecies, although writers are not agreed on this point at preſent.

Ammodytes. Brown or pale blueiſh, with a dentated black dorſal band: noſe terminated by an erect wart. *Coluber ammodytes* abdominal ſcuta 142, ſubcaudal ſcales 32. Linn. Amoen. Ac. Weigel Abh. *Vipera illyrica*, Laur. Amph. *Driunus*, Bell. *Ammodytes*, Aldr.

Inhabits the Eaſt, and mountainous parts of Illyria. This ſpecies is greatly allied to the viper, from which it is diſtinguiſhed principally by the erect proceſs at the tip of the ſnout. The colour is uſually blueiſh grey or brown, with a continued black dorſal band, reſembling that of the viper. This is conſidered as an extremely poiſonous ſpecies, and according to Matthiolus, proves fatal in the ſpace of three hours. The fleſh is uſed medicinally for the ſame purpoſes, as that of the common viper.

Lachesis. Yellowiſh-grey, variegated with brown; a black tranſverſe band above the eyes.—*Cobra lacheſis*, Laur. Amph. *Serpens ceilonica*, Bitin. *Dicta*, Seba.

Deſcribed and figured by Seba, from whom it appears this ſpecies is a native of Ceylon, and is known by the name of bitin. Its colour is a rich and ſomewhat irregular variation of deep and light brown, diſpoſed in ſtreaks and patches, on a yellowiſh grey ground. The ſcales, which in many parts are tipped with white, are large, ſtrongly carinated, and fixed only at the baſe, while the remainder is looſe or free. This ſingular diſpoſition of the ſcales, affords the animal an opportunity of elevating or depreſſing them at pleaſure, and in moving, is ſaid to occaſion a kind of ruſtling noiſe.

This is a poiſonous ſpecies, being armed with large fangs, and from its general form, appears to be an animal of conſiderable ſtrength. The head is indiſtinct, or not diſtinguiſhed from the reſt, by any contraction, or appearance at the neck. The male is deeper coloured than the female, and ſeems to have the body larger, and the tail more ſlender. The general length of this ſnake, ſeems to be about four or five feet, and the tail ſhort in proportion to the body.

Clotho. Greyiſh-orange; variegated with numerous waved black bands; keel of the ſcales on the chin with a white ſpot; tail very ſlender.—*Cobra clotho*, Laur. Amph. *Vipera*, Bitin. *Ceilonica elegantiſſima*.

Inhabits Ceylon and Cuba, and is ſuppoſed to be a poiſonous ſpecies. This appears to be from the work of Seba to be a large ſnake, meaſuring more than ſix feet in length, and being thick in proportion ; the head large, covered with minute ſcales, and as in the coluber lacheſis, ſcarce diſtinguiſhed from the body, by any perceptible contraction at the neck. The colour of the upper parts, is greyiſh orange freckled with black ſpecks, and marked with tranſverſe undulated, or ſomewhat zig-zag bars of black. The under parts are cinereous, variegated with a few black bars, and tranſverſe ſtripes.

ATROPOS. Hoary, with a quadruple ſeries of large brown ocellar ſpots, with white margins. *Coluber atropos*, abdominal ſcuta 131, ſubcaudal ſquamæ 22. Linn. *Cobra atropos*, Laur.

The length of this ſpecies is about ſixteen inches ; the head large, marked with four or five duſky ſpots, and covered with ſmall ſcales : the body rather bulky : the tail is ſhort, meaſuring about a ninth part of the whole length. It is a native of America, and is conſidered as an extremely poiſonous animal.

TISIPHONE. Body thick, brown, and without variegations, *Coluber tiſiphone*. Shaw. Gen. Zool. *Black viper*, Cateſby.

This, according to Cateſby, is the ſize of the black American viper, meaſuring about two feet in length, and being large in proportion ; he tells us it is a ſluggiſh reptile, advancing deliberately even to eſcape danger, but will yet defend itſelf when attacked with much fierceneſs, and its bite is ſaid to be very venomous. It is found in Virginia, and Carolina, in the laſt of which it is called the truncheon ſnake. This ſpecies preys on lizards, and other animals.

MEGAERA. Brown, varied with yellow : head flat and heart-ſhaped, and a large orifice between the eyes and noſtrils on each ſide. *La Vipere Fer de-lance*, Cepede.

This is a large ſpecies meaſuring five or ſix feet in length. It inhabits the iſland of Martinico and ſome of the neighbouring iſlands, and is conſidered one of the moſt formidable of the ſerpent tribe. A ſpecimen of this ſnake, preſerved in the Britiſh Muſeum, is a rich deep brown, with yellow variegations, the back being marked throughout the whole length, by pretty numerous equidiſtant, broken, and ſlightly alternating bars of dull yellow, which, deſcending and joining at intervals with the neighbouring ones, form obſcurely annular and ſomewhat irregular markings of ſimilar colour along the ſides, with ſtill more obſcure croſſings on the part neareſt the ſcuta, intermixed with ſmaller patches and ſpots : the abdomen is dull yellow, clouded and ſpeckled on the ſides with pale brown. The head is large, flat, heart-ſhaped, and covered with very ſmall carinated ſcales ; but the terminal ſcale of the noſe, and thoſe at the ſides of the mouth, are very large, and above each eye is alſo a very large ſcale. The noſtrils are ſmall, and between them and the eyes on each ſide is a large orifice, which has been regarded as a paſſage to the organ of hearing ; the ſcales on the whole upper parts of the body are moderately large, ovate, and carinated, the back ſlightly elevated, the ſides rather ſloping, and the abdomen flattiſh.

The fangs of this ſerpent are of a large ſize, about three quarters of an inch in length, and curved. The poiſon is ſaid to reſemble that of moſt ſerpents, being a clear yellowiſh fluid, like olive oil. The ſymptoms are ſuch as follow from that of the viper, but in a much ſtronger degree. When preparing to bite, it is ſaid to throw itſelf into a ſpiral form, and to ſpring with great rapidity on its prey, but at other times to be rather ſlow in its motions, and of a torpid nature, concealing itſelf beneath the herbage, or within the hollows of trees. It frequents ſugar plantations, for the ſake of the rats, which abound in ſuch ſituations, and alſo preys on birds. The female goes ſix months with young, and produces the new brood perfectly formed, and amounting to forty, fifty, or even ſixty : they are obſerved to vary in colour when young, ſome being yellow, others grey, and others intermixed, yellow, grey, and brown.

COBELLA. Brown, lineated with white : head broad with a lead coloured ſtripe behind each eye. *Coluber cobella*, abdominal ſcuta 150, ſubcaudel ſcales 54. Linn. Amoen. Acad. *Coluber ater, lineolis albis*, Boddaert. *Ceraſtes cobella*, Laur. Amph.

Grows to the length of two feet nine inches, and varies much in the diſpoſition of its colours, and the number of its abdominal ſcuta, and ſubcaudel ſcales. Gmelin enumerates no leſs than fourteen variations of this kind. It is a very common ſnake in America.

COBRA. Entirely brown, compreſſed : back carinated, ſcales of the ridge largeſt ; head elongated and rounded. Gmel. Laur. Amph. Allied to the coluber redi.

CORONATUS. Deep black, with white unequal ſpots and dots. Gmel. *Ceraſtes coronatus*. Laur. Amph. Inhabits New Spain.

NOVÆ HISPANIÆ. Above black, beneath white ; back with oblique ſtreaks, poſterior parts with oblique bands. Gmel. *Ceraſtes mexicanus*, Laur. Amph.

Reſembles C. coronatus, and like that ſpecies, inhabits New Spain.

NATRIX. Brown, with a black and yellow patch on each ſide the neck, and a row of black ſpots down each ſide ; abdomen duſky. *Coluber natrix*, abdominal ſcuta 170, ſubcaudal ſcales 60. Linn. Fn. Suec. *Natrix vulgaris*, Laur. Amph. *Natrix torquata*, Raj. *Gemeine ſchlange*, Meyer. Thiere. *Common ringed ſnake*, Penn.

Inhabits moſt parts of Europe, where it frequents woods, moiſt hedges, and ſhady places. Many varieties of this ſnake are deſcribed by writers, but the colour is in general either a blueiſh grey, or pale olive above, the ſides variegated with black, and the under parts a mixture of black and white. The head is rather ſmall comparatively, and is covered with large ſcaly plates ; the tail is of moderate length, and gradually tapers to the extremity.

This ſnake preys on frogs, mice, and ſmall birds, inſects, and worms, and occaſionally frequents the water in ſearch of the firſt ; it is capable of ſwimming, but not well. It depoſits its eggs in any warm and moiſt ſituation in the form of a continued chain or necklace of ova, to the number of twelve, fourteen, ſixteen, or even twenty, of the ſize of thoſe of a blackbird, and of a whitiſh colour, and it appears are hatched in the ſpring following. During the winter the ſnake conceals itſelf and becomes nearly torpid, and re-appears in the ſpring, at which ſeaſon it is ſaid to caſt its ſkin ; we ſuſpect that it caſts its ſkin twice every year. This is not a poiſonous ſpecies.

ATROVIRENS. Black green ſpeckled with yellow ; abdomen yellow, with a row of black ſpecks down each ſide. *Anguis æſculapii niger*, Aldr. Serp. *La coleuvre verte et jaune*, La Cepede.

A ſpecies oftentimes confounded with the preceding : it is deſcribed with accuracy by La Cepede, who informs us it is frequent in ſome provinces in France. Its haunts are woods, and moiſt ſhady places ; in ſize and general appearance it reſembles the ringed ſnake, coluber natrix, but differs in colour, being of an extremely dark or blackiſh green, appearing at the firſt view entirely black : the ſides are marked with numerous rays of yellow ſpecks, of different forms, ſome oblong, and ſome ſquare ; the eyes and edges of the mouth are bordered with yellow ſcales ; the abdomen is alſo yellow, every plate being marked on each ſide with a black ſpeck. This ſnake is perfectly harmleſs. La Cepede relates from M. Bromare an anecdote relative to a ſnake, which he ſuppoſes to have been of this ſpecies, and which had been ſo completely tamed by a lady as to come to her whenever ſhe called it; follow her in her walks, wreath itſelf round her arms, and ſleep in her boſom. One day, when this lady went in a boat to ſome diſtance up a large river, ſhe threw the ſmake into the water; imagining that it would readily recover the boat by ſwimming; but the current proving unuſually ſtrong at that juncture owing to the advance of the tide, the poor animal in ſpite of all his efforts to reach the veſſel was unfortunately drowned.

GRONOVIANUS. Blueiſh-aſh, beneath blackiſh; a white arched ſpot each ſide the hind head, and one black: back-waved with black. Gmel. Laur. Amph.

Bears a near affinity to the preceding, and is perhaps a variety only of the former, coluber natrix. Number of plates and ſcales not aſcertained.

HUMANUS. Black ſpotted with white; tail alternately ſtriped with black and white. *Coluber humanus*, Gmel. *Natrix humana*, Laur. Amph.

A ſnake very commonly domeſticated in New Spain; and alſo ſaid to inhabit Amboyna.

PUNCTULATUS. Fuſcous, with very minute ſpots of white. Gmel. *Natrix punctata*, Laur. Amph. Native country unknown.

TYROLENSIS. Abdominal ſcuta 178, ſubcaudal ſcales 60. Gmel.

Deſcribed after Scopoli, who informs us it inhabits the Tyroleſe country and depoſits its eggs among ſtones, theſe are white and leathery, with a lateral yolk and turbid watery white, and are found ſticking together in cluſters of about fourteen in number.

BIPES. Abdominal ſcuta 116, ſubcaudal ſcales 58. Gmel. Scop. ann. hiſt.

Mentioned by Scopoli as an inhabitant of the Tyroleſe waters. This kind preys on fiſh and frogs; and is ſaid to be furniſhed with two ſhort proceſſes or feet; the eyes are red or tawny, lower jaw whitiſh, dorſal ſcales elliptic and marginate; ſides ſpotted with white: plates of the belly whitiſh, with a brown ſpot in the middle.

AUSTRIACUS. Blueiſh-grey, with a double dorſal row of rufous ſpots, and reddiſh ſides and abdomen. *Coronella auſtriaca*, Laurenti. *La Liſſe*, Cepede.

This bears a general reſemblance to the common ſnake, coluber natrix, and ſeems to have been firſt deſcribed by Laurenti, who ſpeaks of its being common round Vienna: it occurs alſo in France, and ſeveral other parts of Europe. The principal diſtinction between this ſpecies and the coluber natrix conſiſts in the perfect ſmoothneſs of its ſcales, thoſe of the natrix being ſomewhat carinated. This animal inhabits moiſt meadows, hedges, and ſwampy places, and bites with much eagerneſs, but is incapable of doing any injury, as nature has not provided it with poiſonous fangs. It is ſaid to be eaſily tamed, in which ſtate it ſhows a conſiderable degree of attachment.

ÆSCULAPII. Whitiſh, with double black tranſverſe zones; abdomen whitiſh, variegated with black. *Coluber æſculapii*, abdominal ſcuta 180. ſubcaudal ſcales 43. Linn. *Natrix æſculapii*, Laur. *Coluber albus annulis nigris*, Boddaert.

Length from eighteen inches to two feet; the colour pale whitiſh with a more obſcure caſt on the back, and is marked throughout with nearly equidiſtant black bands, each ſurrounding the body, and divided half way up from the abdomen by a line or narrow ſtripe of the ground colour; thus giving a bifid appearance to the lower part of each band. The head is covered with large ſcales, and marked on the fore part by a tranſverſe black bar running acroſs the eyes. This is a native of South America, and is ſaid alſo to inhabit ſome parts of Aſia.

NAJA. Yellowiſh brown; on the back of the neck a large ſpectacle ſhaped ſpot. *Coluber naja*, plates of the belly 193; ſcales of the tail 10. Linn. *Naja luteſcens*, Laur. Amph. p. 91. *Serpens Malabarica cobra de capello dicta.* Seb. *Spectacle ſnake, nagoo*, Ruſſell. Ind. Serp. Shaw Gen. Zool.

The coluber naja is a native of India and the Ternaet iſlands, where it appears to be one of the moſt common, as well as moſt noxious, of the ſerpent tribe; very frequently proving fatal in the ſpace of a few minutes to thoſe who unfortunately experience its bite. The form of this ſpecies is very remarkable: its general length ſeems to be three or four feet, and the diameter of the body about an inch and a quarter. The head is comparatively rather ſmall, and is covered on the fore part with large ſmooth ſcales, as in the greater number of innoxious ſerpents; the ſcales on the back part and ſides of the head, and alſo on the neck are ſmaller and ovate: thoſe on the remainder of the animal, on the upper part oblong oval, not ill reſembling the general form of a grain of rice. At a ſmall diſtance beyond the head is a lateral ſwelling or dilation of the ſkin, which is continued to the diſtance of about four inches downwards, where the outline gradually ſinks into the cylindrical form of the reſt of the body. This part is extenſile at the pleaſure of the animal; and when viewed from above, while in its moſt extended ſtate, is of a ſomewhat cordated form, or wider at the upper than the lower part, and is marked with a ſingular ſpectacle-formed ſpot of black and white, the mark itſelf being white, and the edges black, and the middle of each of the rounded parts black. This mark is more or leſs diſtinct in different individuals, and alſo varies occaſionally in ſize and form, or in ſome inſtances is altogether wanting. The uſual colour of the animal is a pale ferruginous brown above; the under parts blueiſh-white, ſometimes ſlightly tinged with pale brown, or yellow; the tail, which is of a moderate length, tapers gradually and terminates in a ſlender, ſharp pointed extremity. The title of *cobra de capello*, or hooded ſnake, has been given to this formidable reptile by the Portugueſe, from the appearance which it preſents when viewed in front in an irritated ſtate, or when preparing to bite, at which time it bends the head rather downwards, and ſeems hooded, as it were, in ſome degree by the expanded ſkin of the neck.

Laurenti enumerates four varieties of this hooded ſnake, *Naja luteſcens*, the common kind; β *Naja faſciata faſciis per totum corpus ex fuſco rubris*, having fuſcous red bands over the whole body γ *Naja ſiamenſis, ex cinereo griſea, ſummo dorſo rufo.* Cinereous, with the back rufous; and δ *Naja maculata, ex luteo rufa, ſquamis ſingulis alba macula notatis*; of a tawny yellow colour, and having every ſcale marked with a ſingle white ſpot. But it appears from the work of Dr. Ruſſell "On the Serpents of India," that there are many other varieties of this extraordinary ſnake. He deſcribes no leſs than ten different kinds that are found in India alone, and ſeems to intimate that thoſe are not the whole of the Nagoo tribe which infeſt that part of the world. It is poſſible, on further inveſtigation, ſome of thoſe deſcribed by Dr. Ruſſell as varieties may prove to be ſpecifically diſtinct: according to the character laid down by Linnæus, taken from the number of the abdominal plates and ſcales on the belly, they are clearly ſo; but it is not on this criterion, the fallacy of which is too apparent, that we hazard an opinion; we allude to the different conformation of the ſpectacle-like mark on the back of the neck, and ſtill more to the diſſimilarity obſervable in the figure of the ſcutæ and laminæ; the variations in colour are but ſecondary particulars in conſideration. Dr. Ruſſell enumerates the varieties above-mentioned in the following order.

1. *Arege nagoo.* With a pale central ſpot in the middle of each of the black ſpots of the ſpectacle-ſhaped mark. Abdominal ſcuta 189, ſubcaudal ſcales 60.

2. *Coodum nagoo.* This variety is darker than the other; and the ſkin is of a yellower caſt; but the principal diſtinction is in the ſpectacle-mark, which conſiſts of an oblong curved frame without the uſual black eyes or centre-ſpots of the others. Abdominal ſcuta 187, ſubcaudal ſcales 57.

3. *Sankoo nagoo.* The chief diſtinction of this is a plain hood, without any mark. This variety is ſuppoſed by Seba to be the female of the ſpecies; but Dr. Ruſſell informs us that one which he brought home from India, and preſented to Mr. John Hunter was a male, and that the uſual ſpectacle-ſhaped mark is found indifferently both on the males and females. This variety is more rare than the reſt. Abdominal ſcuta 183, ſubcaudal ſcales 56.

4. *Mogla nagoo.* The cervical ſcuta in this variety are ſpotted here and there with faint greyiſh ſpots, and four of the middle ones are entirely of a blueiſh-grey. Abdominal ſcuta 192, ſubcaudal ſcales 65.

5. *Malle nagoo.* The colour of this variety is of a lighter brown than the reſt, and the ſcuta whiter; and leſs ſpotted, but ſeven of the pectoral ones are completely dark. Abdominal ſcuta 191, ſubcaudal ſcales 62.

6. *Cumbo nagoo.* In this ſome deviations were obſervable in the laminæ: all the cervical ſcuta were duſky, and the trunk had a ſtrong blueiſh caſt. Abdominal ſcuta 186, ſubcaudal ſquamæ 60.

7. *Jenna nagoo.* The ſkin of the hood in this is tinged with orange colour; the ſcuta of the neck ſpotted with grey, and ſix of the lower ones wholly of a blue grey. Abdominal ſcuta 189, ſubcaudal ſquamæ 57.

8. *Nella tas pam.* With the black on the hood unuſually deep, and all the jugular ſcuta remarkably duſky. Abdominal ſcuta 186, ſubcaudal ſquamæ 62.

9. *Kiſtna nagoo.* The middle lamina of the three between the eyes remarkably broad, and the poſterior part ſubovate inſtead of ſemi-cordate; five of the jugular ſcuta duſky, and ſix of the pectoral almoſt black. Abdominal ſcuta 186, ſubcaudal ſquamæ 63.

10. *Korie nagoo.* The three laminæ between the eyes remarkably narrow; the large poſterior pair oval; colour of the trunk, and ſtill more of the ſcuta unuſually blueiſh. Abdominal ſcuta 184, ſubcaudal ſquamæ 57.

The cobra de capello, it is obſerved, is every where exhibited publicly as a ſhow in India; and is of courſe more univerſally known in that country than almoſt any other race of reptiles. It is carried about in a covered baſket, and ſo managed by its proprietors as to aſſume, when exhibited, a kind of dancing motion; raiſing itſelf upon its lower part, and alternately moving its head and body from ſide to ſide for ſome minutes, to the ſound of ſome muſical inſtrument which is played during the time. The Indian jugglers, who thus exhibit the animal, firſt deprive it of its fangs, which renders it incapable of inflicting a poiſonous wound by means of its bite.

Dr. Ruſſell, in his account of various experiments made in India with this ſerpent, aſſures us that as a general ſtandard for a compariſon of the effects of its bite with that of other poiſonous ſerpents, he never knew it prove mortal to a dog in leſs than 27 minutes, and to a chicken in leſs than half a minute. Thus fatal as it is, its poiſon ſeems not ſo ſpeedy in operation as that of the rattle-ſnake, which has been known to kill a dog in the ſpace of two minutes. The following intereſting experiments are related by Dr. Ruſſell to confirm the accuracy of this obſervation.

In the month of June 1787, a dog bitten by a Cobra de capello on the inſide of the thigh, howled at firſt, as if in ſevere pain; after two or three minutes he lay down, continuing to howl and moan; after twenty minutes he roſe, but with much difficulty, being unable to walk, and his whole frame appeared greatly diſordered. He ſoon lay down again, and in a few minutes was ſeized with convulſions, in which he expired twenty-ſeven minutes after. This is the only inſtance mentioned in which the poiſonous bite of the Cobra de capello proved fatal to dogs in much leſs than the ſpace of an hour.—A large and very ſtout dog was bitten by another Cobra de capello on the inſide of the thigh, which in a minute or two was drawn up, the firſt ſymptom in general of the poiſon having taken effect. He continued, however, nearly half an hour longer walking on the three remaining legs, ſeeming not otherwiſe diſordered; but after this time, he laid himſelf along in great inquietude, his head and throat being convulſed in an uncommon degree; he made ſeveral vain efforts to riſe, his legs became both paralytic, and after continuing in this ſtate for an hour, he expired.—A large dog was bitten by a Cobra de capello which had been captive only two days. He complained a good deal at the inſtant of the bite, and the leg was ſoon drawn up. In twenty-five minutes he was ſeized with convulſions, ſucceeded by ſtupor, in which ſtate he lay for ten minutes; the convulſions, however, returned, and he expired in a quarter of an hour, being fifty-ſix minutes after the bite. This experiment was tried on the 11th of November.

Auguſt 9th, a Cobra de capello, which had loſt two of his longeſt fangs, but retained two of the ſecond order, was made to bite a very large ſtout dog. At firſt the dog complained loudly, though without drawing up the thigh, or ſhewing any other ſymptom of poiſon; but happening at this time to break looſe, he was purſued, and brought back, after a chace of an hour and a half, much fatigued and heated. After reſting a quarter of an hour, water was offered to him, which he refuſed, though he eat ſome morſels of bread thrown into it. About a quarter of an hour afterwards he became much diſturbed, grew entirely outrageous, howling violently, ſnapping at and gnawing the ſtake to which he was tied with incredible ferocity. This continued about three hours, when growing faint, his howlings grew weaker, his convulſions increaſed, and he expired about four hours after the bite.—A pig bitten by a ſnake of this kind, which had been fed only once in ſeven days with milk, became greatly diſordered in twenty minutes, and expired in leſs than an hour.—A chicken has been ſometimes known to ſurvive two hours after being bitten by a Cobra de capello. Chickens and pigeons bitten by a Cobra de capello, whoſe fangs had been eradicated, ſuffered no ſymptoms of poiſon; but when poiſon taken from the ſame ſnake was inſerted into their bodies, either by inciſion or puncture, they ſuffered the uſual ſymptoms, and very often died.

It was endeavoured alſo to aſcertain the effects of the bite of the Cobra de capello upon reptiles of the ſame ſpecies, the reſult of which appears doubtful. In ſome inſtances, the bitten animal experienced no kind of injury, while to others the bite proved fatal. An attempt was made, on the 17th of Auguſt 1788, to make a Cobra de capello bite another (of the variety called *Nooni paragoodo*) in the tail, but that part being found too ſmall, the belly was bitten, a little above the vent. The bitten ſnake ſoon loſt its former activity, and when put under a glaſs coiled itſelf up. In this ſtate it was left, and after an hour and a quarter was found dead. On opening the belly, the parts immediately beneath the bite appeared much inflamed, though it could not be diſcovered whether any fangs had penetrated into the cavity.

A Cobra de capello, received by Dr. Ruſſell from Ganjam, under the name of *Saltanag*, was made to bite another remarkably large Cobra brought from the ſame place, under the name of *Coultiah*. The poiſon was ſhed on the place, but no marks of fangs could be perceived, and the Coultiah remained as well as before: this experiment was repeated with the ſame reſult, though a little blood as well as poiſon was found on the part bitten. Some days after this, a Cobra de capello (of the variety called *Coodum nagoo*) was made to bite the Coultiah on the belly; both fangs viſibly acted; blood appeared on the wound, but no other conſequence followed. A *Tar tutta* ſnake, bitten immediately after, in the ſame manner, died within two hours.

RUFUS. Rufous, with diſtant reddiſh-fuſcous bands; ſpectacle-ſpot ſomewhat heart-ſhaped, and marked with four black ſpots. Seba. *Naja braſilienſis*, Laurenti. La Cepede, &c.

Deſcribed by Seba and others after him as a native of Braſil. This is perhaps a variety of the preceding.

BUCEPHALUS. Brown, with tranſverſe whitiſh bars; head large, cordated, and depreſſed; body compreſſed; tail very ſlender. *Serpens luſitanis cobra de capello dicta*, Seba. *Coluber bucephalus. bull-headed ſnake*, Shaw Gen. Zool.

According to Seba, this ſpecies is a native of Ceylon; he conſiders it as a kind of Cobra de capello, or hooded ſnake, in which reſpect he is miſtaken. The length of this ſnake is between four and five feet; the head is extremely large, depreſſed, cordated behind, ſomewhat compreſſed at the ſides of the mouth, and covered above by very large ſcaly plates. At ſome diſtance from the eyes are two remarkable, oblong, brown ſpots. The neck is thin, and, together with the whole body, extremely compreſſed on the ſides; tail long, round, and tapering to a fine point. From the head, along the back, runs a row of large, broad, hexagonal ſcales, thoſe on the other parts are ovate; the abdominal plates are very narrow. The general colour of the animal is rufous-brown, with moderately diſtant, broadiſh, tranſverſe, pale bands, each of which, at its juncture with the ſcuta, is marked with a white ſpot.

RUSSELLI. Browniſh-yellow, with acutely-ovate, blackiſh, dorſal ſpots, edged with white; lateral ſpots ſmaller and ovate. *Ratuka rekula poda*, Ruſſ. Ind. Serp. *Ruſſelian ſnake*, Shaw Gen. Zool.

The abdominal plates, according to Dr. Ruſſell, amount, in this ſpecies, to 168, and the ſcales under the tail to 59. The length of this ſnake is about four feet. Its colour an elegant pale yellowiſh-brown, marked throughout the whole length of the back with a continued ſeries of large ovate ſpots of a deep brown colour, paleſt in the centre, and ſurrounded by a narrow line of white. In ſome parts thoſe ſpots are nearly confluent; on each ſide of the body is a row of brown oval ſpots, ſmaller than thoſe on the back; and beſides theſe, a few ſtill ſmaller tranſverſe marks are ſparingly ſcattered on the ſides; the under part of the body is white, with a few duſky ſpots; the head is rather large, the ſnout obtuſe, the mouth wide, the fangs large, and, as in ſeveral other poiſonous ſerpents, double, a ſmaller fang being ſituated cloſe to the larger one on each ſide.

Dr. Ruſſell informs us, this ſpecies is ſcarce leſs common in India than the Cobra de capello; but from its not being carried about, like that and ſome other ſnakes, as a public ſhow, is not ſo univerſally known either among the natives or Europeans.

Several experiments were made by Dr. Ruſſell to determine the effects of its bite, from which it appears to be one of the moſt poiſonous of its tribe. A chicken bitten in the pinion by one of theſe ſnakes, which had been caught two or three days before, and ſeemed in high ſpirits, was inſtantly infected, ſeized with convulſions, and expired in thirty-eight ſeconds. Immediately after the chicken, a ſtout dog was bitten in the thigh; within leſs than five minutes he appeared ſtupefied; the thigh was drawn up, and he frequently moved as if in pain. He remained, however, ſtanding, and eat ſome bread that was offered to him. In about ten minutes the thigh became paralytic; in fifteen minutes he entirely loſt the uſe of the wounded thigh, and lay down, howling in a diſmal manner, frequently licking the wound, and making, at intervals, ineffectual attempts to riſe. In nineteen minutes, after a ſhort ceſſation, he again began to howl, moaned often, his breathing became laborious, and the jaws were completely ſhut. The few ſucceeding minutes were paſſed alternately in agony and ſtupor, and in twenty-ſix minutes after the bite he expired. A ſecond dog, of much ſmaller ſize, was next bitten, and expired in the ſpace of ſix hours. After this, a rabbit was expoſed to the bite of the ſnake, and died in leſs than an hour; and, laſtly, a chicken bitten in the pinion expired in leſs than ſix minutes. The whole of the above experiments were made with the ſame ſnake in the courſe of the ſame morning.

GRAMINEUS. Green, beneath yellowiſh, with the edges of the abdomen ſpotted with green. *Boodro pam*, Ruſſell Ind. Serp. *Graſs-green ſnake*, Shaw Gen. Zool.

The length of this kind is about thirty inches. The head is rather large in proportion, and obtuſely tapering, but not pointed, and is covered entirely with very ſmall ſcales; the colour is as above deſcribed. This is a native of India, and was firſt deſcribed by Dr. Ruſſell; it is of the poiſonous kinds, and has the fangs remarkably long and ſlender. From the experiments of the laſt-mentioned writer it appears, that a chicken died, after having ſuffered ſtrong convulſions, and afterwards ſtupor, in about eight minutes from the bite; pigs and dogs were ſeized with a ſtupor, convulſions, &c. but in a few hours recovered from the effect of the poiſon.

CROTALINUS. Cinereous, marked above with large alternate blackiſh ſpots; beneath yellow, freckled with brown. *Coluber crotalinus*, abdominal ſcuta 154, ſubcaudal ſcales 43. Linn.

A large ſpecies, with the habit of the rattle-ſnake; the head is heart-ſhaped, the eye-lids protuberant, ſcales carinated. Native country unknown.

SEVERUS. Cinereous, with oblique linear whitiſh bands, edged with brown. *Coluber ſeverus*, abdominal ſcuta 170, ſubcaudal ſcales 42. Linn.

Length about ſeventeen inches; thickneſs moderate; head broad, obtuſe, livid, with cinereous band between the eyes, and behind the noſe; eyes large; neck thick; the colour of the upper parts as before deſcribed; the abdomen duſky; ſides ſpeckled with white; tail ſhort. The figure in Seba, quoted by Linnæus, is of a pale rufous colour, with yellowiſh bands, ſomewhat reſembling Hebrew characters in form, and edged with brown; the abdomen pale yellow, with a row of blackiſh ſpots on each ſide.

PORPHYRIACUS. Violet-black, with the abdomen and ſides crimſon, the ſcuta margined with black. Zool. New Holl. p. 27. pl. 10. Abdominal ſcuta 188, anal ſcuta 7, ſubcaudal ſquamæ 45.

Firſt deſcribed by Dr. Shaw, who ſpeaks of it as a moderately large and beautiful ſpecies; the general proportions nearly the ſame with thoſe of Coluber natrix, the common Engliſh ſnake. The head is rather ſmall, and covered in front with large ſcales; the colour of the head and whole under-parts very fine deep violet; ſides and abdomen crimſon, deepeſt on the fore-part, the large ſcales near the ſcuta being carmine-coloured, with black tips; the abdomen roſe-coloured, with a tinge of yellow, each ſcutum deeply edged with black, thus forming a beautiful ſeries of tranſverſe black bars down the abdomen. The tail meaſures about a ſixth part of the whole length, and is furniſhed beneath, excluſive of the divided ſubcaudal ſcales, with about ſeven ſcuta, or undivided laminæ, commencing immediately beyond the vent, which is edged with ſimilar ſmaller ſquamæ; the colour of the under parts of the tail is a blueiſh-aſh, the roſe-colour of the abdomen ceaſing at the commencement of the tail. In the Zoology of New Holland, Dr. Shaw deſcribes this ſpecies as deſtitute of fangs, and conſequently innoxious; an error ariſing from the mutilated ſtate of the ſpecimen he examined. The ſnake has been ſince obſerved to be furniſhed with thoſe organs; and, as Dr. Shaw remarks, in his General Zoology, to be highly dreaded by the natives of Auſtralaſia, as a poiſonous ſpecies.

Hæmachates. Red, clouded with white; abdomen yellowiſh-white. *Serpens aſiatica hæmachates dicta*, Seba. *L'hæmachate*, Cepede.

Seba deſcribes this ſnake as a native of the Eaſt Indies, having received it from Perſia and Japan. Its general length is about two feet or more; its colour red, varying to deeper or paler in different individuals, and ſometimes inclining to brown; the variegations white or whitiſh. The head is moderately large, and covered in front with large ſcales; tail extremely ſhort and tapering to a point. La Cepede conſiders it a poiſonous ſnake.

Aquaticus. Brown, with the abdomen banded with black and yellow. *Water viper*, Cateſby.

We are acquainted with this ſpecies only from the account given of it by Cateſby. "This ſerpent (ſays that writer) is called in Carolina the water rattle-ſnake; not that it hath a rattle, but is a large ſnake, and coloured not much unlike the rattle-ſnake, and the bite ſaid to be as mortal. This ſnake frequents the water, and is never ſeen at any great diſtance from it. The back and head are brown, the belly tranſverſely marked with black and yellow alternately, as are the ſides of the neck; the neck is ſmall; the head large, and armed with the like deſtructive weapons as the rattle-ſnake; it is very nimble, and particularly dextrous in catching fiſh. In ſummer great numbers are ſeen lying on the branches of trees hanging over rivers, from which, at the approach of a boat, they drop down into the water, and often into the boat on the men's heads. They lie in this manner to ſurpriſe either birds or fiſh, after which laſt they plunge, and purſue them with great ſwiftneſs, and catch ſome of a large ſize, which they carry on ſhore and ſwallow whole. One of theſe I ſurpriſed ſwimming aſhore with a large cat-fiſh in his mouth. The tail is ſmall towards the end, and terminates in a blunt horny point, about half an inch in length, and which, though harmleſs, is conſidered as of dreadful efficacy, by the credulous vulgar, who believe that the animal is able, with this weapon, not only to kill men and other animals, but even to deſtroy a tree by wounding it with it, the tree withering, turning black, and dying."

Lacteus. Milky-white, the back marked by double black ſpots; head black, with a longitudinal white line. *Coluber lacteus*, abdominal ſcuta 203, ſubcaudal ſcales 32. Linn.

Length eighteen inches. A native of India and South America, and is reputed poiſonous.

Niveus. Snowy-white, without variegations. *Coluber niveus*, abdominal ſcuta 209, ſubcaudal ſcales 62. Linn. Inhabits Africa.

Melanis. Deep black; ſides clouded with blueiſh, the eyes brown, with the edge of the pupil ſilvery. *Coluber melanis*, abdominal ſcuta 148, ſubcaudal ſcales 27. Gmel. Pallas It.

Obſerved by Dr. Pallas on the borders of the Volga and Samara rivers in Siberia. It has the general appearance of the viper, but differs in colour, being of a deep black on the back, and of a ſteely luſtre beneath, marked with patches of a deeper caſt, while the ſides are clouded, and ſpotted at intervals with blueiſh. The eyes are of a bright white, with perpendicular pupils, and ferruginous irides; tail ſhort, and gradually tapering to the tip.

Buccatus. Whitiſh, with large double brown dorſal ſpots; head ſomewhat depreſſed, cheeks timid. *Coluber buccatus*, abdominal ſcuta 107, ſubcaudal ſcales 72. Linn.

A poiſonous ſpecies; it inhabits South America and India. Length twelve inches.

Atrox. Grey brown, with tranſverſe linear whitiſh ſtripes; abdomen duſky with white tranſverſe variegations. *Coluber atrox*, abdominal ſcuta 196, ſubcaudal ſcales 69. Linn.

Length about eighteen inches; it is a poiſonous ſnake, and is a native of the iſland of Ceylon.

Corallinus. Glaucous, with ſcales ſomewhat heart-ſhaped, and three brown lines down the back. *Coluber corallinus*, abdominal ſcuta 193, ſubcaudal ſcales 82. Linn.

Linnæus deſcribes this as a poiſonous ſpecies: it is a native of the eaſtern regions; it preys on lizards.

Leberis. Pale; head white; body marked above with linear black bands. *Coluber leberis*, abdominal ſcuta 110, ſubcaudal ſcales 50. Linn.

Deſcribed by Kalm, who informs us that it is a native of Canada, and that the upper parts are traverſed by linear black bands; the head white with two rufous ſpots on the top, and a triangular ſpot over the noſe. Linnæus mentions it as a poiſonous ſpecies, a particular conſidered doubtful by Dr. Gray.

Aulicus. Grey brown, with tranſverſe white bands bifurcating over the ſides. *Coluber aulicus*, abdominal ſcuta 184, ſubcaudal ſcales 60. Linn.

The length of this ſpecies is ſix inches; it inhabits America, and is one of the poiſonous kind of ſnakes.

Elegantissimus. White; head variegated with black; body marked above by a quintuple ſeries of ocellated red ſpots. *Coluber elegantiſſimus*, Gmel. Laur. Amph. *Serpens lemniſcata venuſtiſſima Americana*, Seba.

This is a beautiful ſpecies, meaſuring in length about two feet; the colour is white, marked down the upper part with a quintuple ſeries of black ſpots with red centres; the middle row is compoſed of very ſmall ſpots, the next on each ſide with larger ocellated ones, and the loweſt on each ſide, next the ſcuta, reſembling that on the middle of the back, and conſiſting of ſmall ſpecks; the head is marked by a croſs-ſhaped ſpot on the top, and by a few blackiſh ones acroſs the ſnout; the tail is ſhort, meaſuring two inches and a half in length, and tapering to a point.

Rhombeatus. Glaucous, with blackiſh lozenge-ſhaped ſpots, blue in the middle. *Coluber rhombeatus*, abdominal ſcuta 157, ſubcaudal ſcales 70. Linn.

Length from two to three feet; colour, in general, grey, ſometimes browniſh, with three alternating rows of ovate duſky ſpots, with large blue centres; the abdomen is pale or whitiſh, and often clouded with blueiſh grey. This is a native of India and South America.

Javanicus. Grey; head ſtriped with blue; body marked with tranſverſe blue ſtripes edged with golden.

Deſcribed by Mr. Wurmb in the "Memoirs of the Batavian Society," for the year 1787. This is a large and moſt beautiful ſpecies, and is ſeen principally in the rice fields, whence it obtains the name of *Oular-Sawa*, or Rice-field Snake. Thoſe which are found in the higher and more wooded ſituations arrive at a far ſuperior ſize. The head of this ſnake is large and flat, and is covered, as in the major part of the coluber genus, with large ſcaly plates; the mouth is furniſhed with double rows of ſharp teeth, but is deſtitute of fangs, the animal not being of a poiſonous nature; the iris is yellow; upper part of the head grey, mixed with blue; from behind the eyes paſs two blue ſtripes to the upper part of the neck, where they unite into an arch about an inch beyond the head; a third ſtripe of the ſame colour proceeds from the ſnout to the occiput, where it divides into two, and ſurrounds a yellow ſpot marked with a few blue ſpecks; the upper part of the body is divided into a kind of lattice-work, formed by ſtripes of bright blue with gold-coloured edges; the middle parts of the ſquare being of a grey colour, with changeable reflections of yellow, blue, and green; towards the ſides the grey colour is of a lighter or paler caſt, as well as on the tail, where the ſquares are ſmaller than on the back; each ſide of the body is alſo marked by a row of white ſpots, ſituated at the croſſings of the blue ſtripes. This ſnake preys on birds, rats, and various other ſmall animals.

Boæformis. Whitiſh, with brown variegations; white beneath, with very ſhort ſcuta. *Pedda poda*, Ruſſell Ind. Serp. *Boaform ſnake*, Shaw Gen. Zool.

A new ſpecies deſcribed by Dr. Ruſſell. The length of the ſpecimen, examined by that writer, was about two feet and a half; but it is ſuppoſed to attain to a much larger ſize. It was ſhort and thick with moderately large oblong-ovate head, covered with large ſcales; and the tail ſhort and ſharp pointed. The colour of the upper parts very pale or whitiſh brown, variegated on the back and ſides, with large and ſmall irregularly formed, deep-brown patches, and ſpots, thoſe on the ſides being moſtly ocellated. The body is covered with very ſmall ſcales, the three rows next the abdomen being much larger than the reſt; abdomen white, the ſcuta being remarkably narrow or ſhort, and reddiſh at the margins. The under part of the tail is variegated with black and white.

This is a native of India, and is repreſented as an animal of great ſtrength, wreathing round the arm, if held for a ſhort time, ſo cloſely as to numb the hand; it is not poiſonous, its bite producing no other effect than that of temporary pain.

The ſerpent mentioned by Dr. Ruſſell, under the name of *Bora*, is conſidered as a variety of coluber boæformis, and ſo alſo is the *Pedda poda*, t. 23, 24. The firſt is much larger than the ſerpent above deſcribed; the diſpoſition of the ſcales and colours are the ſame, but the ground colour is white, and the tail is furniſhed beneath with ſeveral undivided lamellæ towards the tip, or after thoſe immediately ſucceeding the vent, while the tip itſelf is again terminated by a few divided ſcales. This ſnake is found at Calcutta, where it is pretended the bite is very ſoon followed by eruptions on different parts of the body, though it does not prove fatal in leſs than ten or twelve days, but the whole of this is regarded as a mere popular error. The other ſuppoſed variety, the pedda poda, grows to a very large ſize, having been ſeen nine or ten feet in length. In its general appearance it reſembles that firſt deſcribed, but the ſcales are larger in proportion.

Melanurus. Yellowiſh brown, with black head, and two black ſpots on the tail. Ruſſell. Ind. Serp.

A ſmall ſpecies about ten or eleven inches in length, ſcarcely of the thickneſs of a gooſe quill, and nearly of equal diameter from the head to the tip of the tail. The colour is a light yellowiſh brown, with a dotted black line running from head to tail along the middle of the back, and a few fainter fillets on the ſides; the head is ſmall, ovate, black, and covered with large ſcales; the tail ſhort, ſcarcely meaſuring more than an inch in length, and is marked at its origin on the upper part, by a large rhomboidal black ſpot edged with white; and having a white ſpeck in the middle; the tip of the tail is alſo marked by a ſimilar black ſpot; the abdomen is of a pale orange colour, and the under part of the tail white, ſpeckled, and variegated with black. The bite of this ſpecies is ſaid to be painful but not poiſonous. It is a native of India, and is deſcribed among the ſerpents of that country by Dr. Ruſſell.

Jara. Black, with double linear white ſpecks, and yellowiſh collar and abdomen. *Jara potoo*, Ruſſell, Ind. Serp.

This is one of the new ſpecies of ſerpents deſcribed by Dr. Ruſſell. It inhabits India. The length is fifteen inches; tail very ſhort and tapering ſuddenly to a point. The abdominal ſcuta are 175 in number, and the ſubcaudal ſcales 56.

Arnensis. Yellowiſh-brown with narrow blackiſh tranſverſe bands edged with white, and pale abdomen. *Arnee ſnake*, Ruſſ. Ind. Serp.

Inhabits the country of Arnee in the Eaſt Indies. The length is about eighteen inches; the colour above yellowiſh, with moderately diſtant blackiſh, or very deep brown, tranſverſe bands which are whitiſh at the margins; the head is ſmall; tail rather ſhort and tapering to a ſharp-pointed tip. Abdominal ſcuta 169, ſubcaudal ſcales 50.

Sagittatus. Brown, with whitiſh ſagittated dorſal ſpots edged with black. *Tar tutta*, Ruſſ. Ind. Serp.

The length of this ſnake is two feet; the head is rather large in proportion, round, obtuſe, and covered with large ſcales; neck and body ſlender, the colour on the upper parts yellowiſh brown variegated, with a chain or ſeries of ſomewhat triangular, or ſagittated ſpots: the abdomen is yellowiſh white, and the ſcuta is marked by a duſky ſpot on each ſide. This is a native of India.

Striatus. Greeniſh black, with ſpotted white bands, and blueiſh-white abdomen. *Gajoo tutta*, Ruſſ. Ind. Serp.

This is much ſmaller than the laſt, meaſuring only fourteen inches: the colour above is greeniſh black, marked with about twenty tranſverſe bands, each compoſed of a number of longitudinal abrupt white or yellowiſh white ſtreaks, and along the ſides of the body are interrupted rows of ſimilar ſtreaks; the head is obtuſe, and covered with large ſcales, the abdomen blueiſh-white. Abdominal ſcuta 174, ſubcaudal ſcales 40.

Fasciolatus. Cinereous, with whitiſh tranſverſe bands and glaucous abdomen. *Nooni paragoodoo*, Ruſſell. Ind. Serp.

Agilis. Banded alternately with white and fuſcous, and varied with black dots: head ſmall; tail ſhort.—*Coluber agilis*, abdominal ſcuta 184, ſubcaudal ſcales 50. Linn. *Ceraſtes Agilis*, Laur.

A native of Ceylon. The head is ſmall, covered with large ſcales; body ſlender and ſmooth, about a ſpan in length, and covered with ſmall ſcales; tail ſhort, taper, and terminating rather obtuſely.

Simus. Blackiſh, with white tranſverſe bands; noſe turned up. *Coluber*.

SIMUS. Abdominal ſcuta 124, ſubcaudal ſcales 46. Linn. D. Garden.

Length eighteen inches; head rather large, and roundiſh, with the noſe flat in front, and turned up into a ſlightly pointed tip: between the eyes is a black curved band, and on the top of the head a white cruciform mark, with a black central ſpot; abdomen duſky. A native of Carolina, and other parts of North America.

PELIAS. Browniſh, with double tranſverſe black bands, beneath green with a yellow lateral band.—*Coluber pelias*, abdominal ſcuta 187, ſubcaudal ſcales 130. Linn.

A native of South America and India. Deſcribed by Linnæus from the Muſeum of Degeer.

MUCOSUS. Blueiſh, beneath pale, with angular head: lips ſtriped tranſverſely with black. *Coluber muſcoſus*, abdominal ſcuta 200, ſubcaudal ſcales 140. Linn. *Natrix mucoſa*, Laur. Amph.

Deſcribed by Linnæus from a ſpecimen in the Muſ. Ad. Fr. It is a ſmall ſpecies, meaſuring about eighteen inches in length; the native country is South America.

CINEREUS. Cinereous; abdomen white; tail recticulated above with brown, and lineated tranſverſely beneath. *Coluber cinereus*, abdominal ſcuta 200, ſubcaudal ſcales 137.

Indies, according to Linnæus South America and India: it reſembles the common ſnake, and is about two feet in length.

DIPSAS. Green with two white ſtripes. Abdominal ſcuta 152, ſubcaudal ſcales 135. Linn. *Serpens ſurinamenſis cærulæ*, Seba. Inhabits Surinam and other parts of South America.

CASPIUS. Body faſciated alternately above with yellow and fuſcous, beneath yellow. *Coluber caſpius*, Gmel. Lepech. It.

Firſt deſcribed by Lepechin as an inhabitant of the ſhores of the Caſpian ſea, where it haunts the low grounds and buſhy places. It is reported of this ſpecies, that when diſturbed it firſt endeavours to eſcape, but if purſued or irritated, ſprings forwards on its aſſailant with great fury, though incapable of doing any injury by its bite. The uſual length is about five feet.

PERUVIANUS. Black and white; abdomen roſe-coloured. *Serpens Peruviana elegantiſſima et rara*, Seba.

A native of Peru; deſcribed by Seba, who informs us it is rare in European collections. This is an innoxious ſpecies. Linnæus does not notice this ſnake, as the number of its abdominal ſcuta, and ſubcaudal plates could not be aſcertained.

HYGEIÆ. White, with ſomewhat undulated black zones, and head faſciated longitudinally with black. *Serpens ſiamenſis tænoiolis*, &c. Seba.

A ſmall ſpecies of a white colour, barred with numerous irregular black bands, nearly ſurrounding the body; head ſmall, covered with large ſcales, and marked by two broad longitudinal ſtreaks uniting at the top of the ſnout: tail rather ſhort and ſharp pointed. Inhabits Siam.

PETHOLA. Lead colour, with teſtaceous bands. *Coluber pethola*, abdominal ſcuta 209, ſubcaudal ſcales 90. Linn. 207—103. Gronovius. 207—85. Boddaert.

This ſnake inhabits Africa. In the middle of the head, between the eyes is a large ſhining ſhield, compoſed of many plates; the ſides of the head and hind-head is covered with imbricated ſcales each ſide; and the ſnout is ſharp.

No leſs than nine varieties of this ſnake are deſcribed by Gmelin after Laurenti. Theſe we ſhall enumerate in the Gmelinian order, obſerving only that on further inveſtigation it is not unlikely ſome at leaſt of thoſe ſuppoſed varieties may prove to be ſpecifically diſtinct. Thoſe are not noticed by Dr. Shaw, but that writer thinks the C. Petalarius of the Muſeum Adolphi Friderici, can hardly be conſidered as a ſpecies diſtinct from Pethola.

β. *Coronella Africana*, &c. White, with ſpots on the back; thoſe on the anterior part rounded, and gradually becoming rhomboidal, with the edges reddiſh. Laur. Amph.

γ. *Coronella ocellata*, &c. Blueiſh, with a quadruple ſeries of black ocellated ſpots, which are blue in the middle, and are diſpoſed longitudinally. Laur. Amph.

δ. *Coronella faſciata*, &c. Blueiſh white with black brown bands, and two longitudinal divided lines. Laur. Amph.

ε. *Coronella latiroſtrà*, &c. Browniſh, with a few pale bands, ſnout depreſſed. Laur. Amph.

ζ. *Coronella latiroſtra, faſciis*, &c. With yellowiſh confluent bands near the belly. Laur. Amph.

η. *Coronella ceraſtoides*, &c. Browniſh white, with very pale brown ſpots; occipital ſpots two, and longitudinal; dorſal ones eliptic, and diſpoſed in a ſingle ſtripe. Laur. Amph.

θ. *Coronella tæniata*, &c. Middle of the back marked with a brown ſtripe; belly and ſides whitiſh brown. Laur. Amph.

ς. *Coronella anguiformis*, &c. With entire circular brown bands, beneath obliquely concurrent.

PETULARIUS. Brown, with white bands, beneath pale. Abdominal ſcuta 212, ſubcaudal ſcales 102. Linn. Weigel abh. der. hall. Length from twelve to thirty inches; inhabits South America.

LEMNISCATUS. Yellowiſh white, marked at equal diſtances with triple dark brown bands. *Coluber lemniſcatus*, abdominal ſcuta 250, ſubcaudal ſcales 35. Linn. Amoen. Ac. *Natrix lemniſcata*, Laur. *Serpens annulatus*, Seba.

A native of Aſia. The length of this ſnake is about three feet, of a ſlender form, and white or yellowiſh marked throughout the whole length, at equal diſtances, with triple zones of black or deep brown, which entirely ſurround the body. The head is rather ſmall, covered with large ſcales, and marked acroſs the ſnout by a double zone, of which the ſmalleſt diviſion paſſes acroſs the noſtrils, and the largeſt acroſs the eyes. The whole animal is of a ſmooth and ſhining ſurface.

LUBRICUS. Flagelliform; white with equidiſtant black bands; body gloſſy. *Coluber lubricus*, Gmel.

Allied to the laſt ſpecies; the body is white, marked with ſingle black bands; the head is marked acroſs the ſnout by a black band, and at the top by two oblique ſtripes nearly meeting at an angle in front; the ſkin is remarkably ſmooth and gloſſy. The length of this ſnake is eighteen inches. According to Gmelin it is a native of Surinam; the ſnake deſcribed by Seba, as *Natrix lubrica, faſciis rubris*, and which is conſidered as a variety of the ſame ſpecies, is a native of Surinam.

DOLIATUS, milk-white, marked above by large, approximated, ſuboval black rings. *Coluber doliatus*, abdominal ſcuta 164, ſubcaudal ſcales 43. Linn.

A ſmall ſpecies meaſuring from eighteen inches to two feet in length; general colour milk white, marked throughout by large oval jet-black rings, the ends of which approaching each other on the top of the back, give the appearance of double bars, correſponding with the deſcription given of this ſnake by Boddaert, *Colluber albidus, annulis nigris per paria digeſtis*. Inhabits Carolina.

GEMMATUS. Blue, with a black middle-ſtripe ſpotted with white, and two lateral white ſtripes. *Le Chapelet*, La Cepede. Abdominal ſcuta 166, ſubcaudal ſcales 103.

The length of this beautiful ſnake is about fifteen or ſixteen inches; the colour on the upper parts blue, with three narrow equidiſtant ſtripes from head to tail; the two lateral ſtripes being white, the middle one black, marked by a row of ſmall white ſpecks alternately oblong and round, reſembling a ſmall ſtring of beads aud bugles: the head is covered with large ſcales, and marked on each ſide with three or four ſpots, forming a band acroſs the eyes, the top ſpotted with pale blue marks bordered with black; the abdomen white. The ſcuta are each marked at the edge with a ſmall black ſpeck, forming two rows down the abdomen. The native country of this kind is unknown, the ſpecies was deſcribed by La Cepede from a ſpecimen in the royal cabinet.

BILINEATUS. Rufous, with two golden yellow ſtripes. *La double raie*, La Cepede.

This ſnake meaſures twenty-five inches in length, of which the tail exceeds ſix inches. The general colour is rufous; every ſcale is bordered with yellow, and down the back from the head to the tail run two bright yellow ſtripes of a golden hue. The ſcales on the head are large, thoſe on the body ſmooth. The native country is unknown.

TRILINEATUS. Rufous, with three black lines. *La trois raie*, La Cepede.

The length is about eighteen inches; the head is covered with large ſcales; tail about two inches and three quarters long. This is a native of Africa.

TRIFASCIATUS. Body marked with three broad black ſtripes, the middle one divided by a white line, and three ſpotted lines down the abdomen. Shaw Gen. Zool.

A ſmall ſpecies, meaſuring a foot in length, and being rather thick in proportion; head rather large, blackiſh, with the ſutures pale. Deſcribed from a ſpecimen in the collection of Dr. William Hunter.

DIONE. Pale blue, ſpotted with brown, and three whitiſh lines. Pallas It.

This ſpecies is a native of the ſalt deſerts towards the Caſpian ſea, and of the hilly regions near the river Irtin; and was firſt deſcribed by Dr. Pallas. It is of a ſlender form, about two feet in length; the head ſmall, tetragonal and commonly reticulated with blackiſh ſutures. The two intermediate ſpaces between the three lines on the back are marked with a row of duſky alternate ſpots; and the tail is about one ſixth of the whole length.

MYCTERIZANS. Head angular, with ſharp pointed ſnout, and a yellow line on each ſide of the abdomen. *Coluber mycterizans*, abdominal ſcuta 192, ſubcaudal ſcales 167. Linn. *Coluber ſubcæruleus lateribus lineatis*, Boddaert. *Natrix micterizans*, Laur.

This ſnake is in general of a graſs-green colour, and is diſtinguiſhed in particular by the yellow line which extends the whole length of the body on each ſide of the abdomen. It is of a ſlender form, meaſuring about three feet and a half in length, and about half an inch in diameter. The head is moderately large, long, and ſharp ſnouted, the upper jaw extending far beyond the lower. Linnæus was erroneouſly led to conſider this as a poiſonous ſpecies, from the fang-like appearance of the large and long teeth in the upper-jaw. It is a native of many parts of North America, where it is principally ſeen on trees, moving with great velocity in purſuit of inſects, on which it feeds.

Gmelin deſcribes the natrix flagelli formis of Laurenti, and alſo the anguis viridis of Cateſby, as two varieties of the coluber mycterizans. The *Botla Paſſeriki* of Dr. Ruſſell may be perhaps admitted likewiſe as a variety. This differs in the colour of the under parts, inſtead of green being of a cinereous pink colour, elegantly freckled with very numerous minute black and yellowiſh dots; the margin of the ſcuta being edged with dull yellow; the ſkin of the neck alſo, when the animal is irritated, exhibits by the dilatation of the ſkin on that part, a beautiful variegation of black and white recticular marks, which do not appear at other times. This creature is repreſented as of a ferocious nature, hiſſing violently, and ſnapping at any thing oppoſed to it, but producing no other effect by its bite than that of temporary pain in conſequence of mere puncture.

COLUBER NASUTUS. *Serpens viridis, ore acuminato ex Java, aſpidio ſpecies*, Seba.

Whether this be diſtinct from the former is uncertain; the head is ſomewhat larger in proportion, and the body leſs ſlender: in other reſpects it very nearly correſponds. The length is about three feet. This ſnake according to Seba is a native of Java.

LINEATUS. Blue-green, with three or five brown linear ſtripes, the middle one broadeſt. *Coluber lineatus*, Linn. *Serpens ceilonica lineis ſubfuſcis*, Seba.

This ſnake is a native of India, and is commonly about three feet in length. The general colour is pale blueiſh green above, with a golden gloſs, and is marked throughout the whole length by five longitudinal narrow bands, or ſtripes of duſky brown or greeniſh. In young ſpecimens there are rarely more than three ſtripes. The form of this ſnake is long and ſlender, with the head ſmall, the abdomen flattiſh, and the tail long and thin.

JACULATRIX. Whitiſh, with three blackiſh ſtripes, the middle one broadeſt. *Coluber jaculatrix*, Linn. *Serpens Americana xequipiles dicta*, Seba.

Reſembles lineatus, but is ſmaller; the general colour whitiſh tinged with blue, and marked by three longitudinal ſtripes of black or deep brown, of which that in the middle is broadeſt. This appears to vary in colour, that deſcribed by Seba being yellowiſh inſtead of white. The abdominal ſcuta are 163 in number, the ſubcaudal ſcales 77. This kind inhabits Surinam, and is conſidered as a harmleſs animal.

SIBILANS. Blueiſh, with five duſky lines, and the head ſpotted. *Coluber ſybilans*, abdominal ſcuta 166, ſubcaudal ſcales 100.

This, like the laſt, reſembles coluber lineatus, being marked, as in that ſpecies, with five duſky ſtripes, the middle one of which is the broadeſt, and is nearly black, with a whitiſh ſpeck on each of the ſcales. The head is ovate, covered with large ſcales, and marked with ſeveral oblong, blue, ſubangulated ſpots, with black edges; and the tail is very long and ſlender. This animal is of conſiderable ſize, ſometimes meaſuring four feet in length; it is a native of Aſia, and is eſteemed harmleſs.

SITULA. Grey, with a longitudinal duſky band, bounded on each ſide by a black line. *Coluber ſitula*, abdominal ſcuta 236, ſubcaudal ſcales 45. Deſcribed by Haſſelquiſt as a native of Egypt.

SAURITA. Brown, with three blue-green ſtripes. *Coluber ſaurita*, abdominal ſcuta 156, ſubcaudal ſcales 121.

This is the ribbon ſnake of Cateſby, a ſpecies about three feet in length, and very beautiful. The general colour is brown above, with three moderately-broad longitudinal blueiſh-green ſtripes; the head is rather ſmall and ſomewhat pointed, the body ſlender, and the tail thin. Cateſby repreſents it as an animal extremely ſwift in its motions; it inhabits Carolina and many other parts of North America, frequents trees, and is perfectly innoxious.

VITTATUS. Whitiſh, with three black ſtripes, the middle one very narrow; abdomen white, with the edges of the ſcuta brown. *Coluber vittatus,* abdominal ſcuta 142, ſubcaudal ſcales 78. Linn. *Coluber de terragona,* Seba.

The length of this kind ſeldom exceeds thirty inches; the colour is whitiſh, tinged with blue, and marked along the whole length of the back by three black or dark brown ſtripes, the middle one of which is the narroweſt; between this and the principal longitudinal ſtripe on each ſide is a pair of extremely narrow or linear ſtripes, which are gradually loſt after paſſing ſome diſtance down the back. The head is rather ſmall; of an elongated form, covered with large ſcales, and marked with black variegations; the tail is of moderate length, ſlender, and gradually tapering to a point. This ſnake is a native of South America, and is not of the poiſonous tribe of ſerpents.

MONILIS. Whitiſh, with broad brown bands, and three ſpots on the neck. *Coluber monilis,* abdominal ſcuta 164, ſubcaudal ſcales 82. Linn.

A native of South America. This is a ſmall ſpecies meaſuring about a foot and half in length; the colour whitiſh, banded throughout the whole length with very broad tranſverſe brown bars; the head is of moderate ſize, whitiſh, and bordered with brown.

SCABER. Grey, ſpotted with brown, and the ſcales carinated by a riſing point. *Coluber ſcaber,* abdominal ſcuta 228, ſubcaudal ſcales 44. Linn. *Rauhe natter,* Merrem.

Length about eighteen inches, the form rather ſlender; head ſmall, and marked at the back of the neck with a few tranſverſe ſtreaks; the ſpots on the back are ſomewhat rhomboidal, of a brown colour, lighteſt in the centre, and diſpoſed in a triple ſeries. This ſnake is a native of India.

MAURUS. Brown, with two black dorſal lines, ſides tranſverſely banded with black, and the abdomen black. *Coluber maurus,* abdominal ſcuta 152, ſubcaudal ſcales 66. Linn. Syſt. Nat. A native of Algiers.

JUGULARIS. Black, throat ſanguineous. Haſſequiſt. Deſcribed as a native of Egypt; the abdominal ſcuta are 195, and the ſubcaudal ſcales 102.

COCCINEUS. Black, with the back yellow, ſpotted with red, and the abdomen pale. *Coluber coccineus,* abdominal ſcuta 175, ſubcaudal ſcales 35. Gmel.

Length about two or three feet, form rather ſlender, with the head ſmall, the ground colour black, with about twenty-three ſubovate ſpots of bright red, with the ſpaces between yellow. This is a native of South America.

CANDIDUS. White, with large ovate brown dorſal ſpots. *Coluber candidus,* abdominal ſcuta 220, ſubcaudal ſcales 50. Linn. *Serpens æſculapii braſilienſis,* Seba.

General colour milk-white, marked throughout with a row of deep brown ovate patches; the head is brown, and covered with large ſcales; tail of moderate length, gradually tapering to the extremity. This is a native of South America.

NEBULATUS. Clouded with fuſcous and cinereous, beneath varied with white and brown. *Coluber nebulatus,* Linn. Weigel. Abh. Hall. *Ceraſtes nebulatus,* Laurenti.

A native of America. This is of a moderate ſize, meaſuring about two feet in length; the head is rather large in proportion, and covered with ſcales of conſiderable ſize; body rather ſlender, and the tail tapering rather ſuddenly from the body. The colour is yellowiſh brown, clouded with irregular deep-brown, or blackiſh variegations diſpoſed ſomewhat in the form of bands, and nearly ſurrounding the body.

PADERA. White, with blackiſh dorſal ſpots, connected by a line and lateral ſpots. *Coluber padera,* abdominal ſcuta 198, ſubcaudal ſcales 56. Linn. A native of India.

AUSTRALASIÆ. Blackiſh brown, ſpeckled with yellow; ſcuta very narrow, and the abdomen clouded with brown and yellow. *Auſtralaſian ſnake,* Shaw Gen. Zool. White's Journ. New South Wales.

This is a large ſnake, meaſuring nine or ten feet in length, and being rather ſlender in proportion; the colour above deep or blackiſh brown, variegated with numerous yellow ſpecks, ariſing from the circumſtance of the middle of every ſcale being marked with an ovate yellow ſpot. On the ſides of the body many of the ſcales are yellow on one half and black on the other, and by degrees appear more tinged with yellow as they approach the abdomen, which is clouded with a mixture of brown and yellow; the head is ſmall, and covered in front with moderately large ſcales; the teeth rather large, and unaccompanied, ſo far as can be aſcertained from the dried ſpecimens hitherto examined, by any poiſonous fangs.

SCHOCKARI. Cinereous brown, with a double white longitudinal band each ſide; abdomen whitiſh; throat yellowiſh, and ſpeckled with brown. *Coluber ſchockari,* abdominal ſcuta 180, ſubcaudal ſcales 114.

Deſcribed by Linnæus after Forſkal, as being about a cubit and a half in length, and the thickneſs of a finger; the colours as above deſcribed, except that, as the ſnake advances in age, a narrow ſtripe, compoſed of ſmall whitiſh ſpots, is obſervable down the middle of the back. The head is ovate, obtuſe, and covered with large ſcales, and the tail about a third of the whole length. A native of the woody parts of Arabia.

HOELLIEK. Entirely red. Forſk. Forſkal deſcribes this as a native of Arabia. It is about a foot in length; the bite of this ſnake is ſaid to cauſe an inflamed tumour, and its breath to excite an itching in the ſkin.

REGINÆ. Violaceous brown; beneath white, with a ſemi-orbicular brown ſpot on each alternate ſcuta. *Coluber reginæ,* abdominal ſcuta 137, ſubcaudal ſcales 70. Linn. Weigel. Abh. Der. Hall. &c.

Length twelve inches; the tail is of a moderate length, and rather ſlender, and the ſcales beneath are plain. A native of India, and conſidered, by ſome writers, as an inhabitant likewiſe of America.

CYANEUS. Deep blue, beneath cinereous. *Coluber cyaneus,* abdominal ſcuta 119, ſubcaudal ſcales 110. Linn. *Anguiculus ſurinamenſis cyaneus,* Seba.

This is a ſmall ſpecies; the head is of a moderate ſize, rather long, and covered with ſcales of a large ſize; tail long, and tapering gradually to a point. Inhabits South America.

EXOLETUS. Blueiſh-grey; head oblong and flattiſh; lips and throat white. *Coluber exoletus,* abdominal ſcuta 147, ſubcaudal ſcales 132. *Natrix exoletus,* Laur. Amph. p. 78.

Inhabits South America and India. The length is three feet; the ſcales on the body are obtuſe, and arranged in eleven rows; the head oblong and flattiſh; tail ſlender, a foot in length, and pale beneath

DHARA. Coppery-grey, with the edges of the ſcales whitiſh; beneath white. *Coluber dhara,* abdominal ſcuta 235, ſubcaudal ſcales 48.

The length of this ſnake exceeds a cubit; the thickneſs leſs than a finger. The head is ovate, obtuſe, and covered with large ſcales, of which thoſe in the middle between the eyes are larger than the reſt. A native of Arabia. Forſk.

TYRIA. Whitiſh, with a triple ſeries of rhomboidal ſpots. *Coluber tyria,* Linn. Deſcribed by Haſſelquiſt as a native of Egypt

FULVIUS. Fulvous, ſpotted with brown, the body annulated with black bands, and the tail very ſhort. *Coluber fulvius,* abdominal ſcuta 218, ſubcaudal ſcales 31. Linn.

Length about eighteen inches; the head brown above, and covered with large ſcales. A native of North America.

Constrictor. Shining black, with the body very long and ſlender. *Coluber conſtrictor*, abdominal ſcuta 186, ſubcaudal ſcales 92. Linn. *Black ſnake*, Cateſby. Carol.

According to Cateſby, this is a large and very long ſnake, ſome attaining to the length of ſix feet; they are entirely of a ſhining black colour, and are very nimble and beneficial in killing rats, which they purſue with wonderful agility to the roofs and all parts of houſes and barns, where rats are able to run, and for this ſervice are preſerved by moſt of the inhabitants; they are bold and furious, leaping at and biting thoſe that attack them, though no harm enſues, their bite not being venomous; it is commonly ſaid, in Carolina, they will attack the rattle ſnakes, and ſwallow them. "It is certain," ſays Cateſby, "moſt or all ſnakes will devour one another, not only of their own but of all other kinds, which I have often ſeen; one, after a long ſtruggle, ſwallowing another, but little leſs than itſelf."

Sirtalis. Brown, with three blueiſh-green bands. *Coluber ſirtalis*, abdominal ſcuta 150, ſubcaudal ſcales 114. Linn. Deſcribed by Kalm as a Canadian ſpecies.

Decorus. Blueiſh-green, with a double lateral band of black, and black ſpots on each ſide the neck.

A ſpecies deſcribed by Dr. Shaw, from a ſpecimen in the Britiſh Muſeum. Its habit is ſlender and flagelliform; length about two feet and a half; the colour pale, blueiſh, gilded green, with irideſcent variegations; beneath paler, or more inclining to white; on each ſide the body, near the abdomen, a double black ſtripe; head longiſh, covered with large ſcales, immaculate, and marked each ſide, through the eyes, by a broadiſh black ſtripe broken into ſpots, and which, paſſing to ſome little diſtance along the neck, becomes divided, and forms the double lateral ſtripe before mentioned. The eyes are large: tail very long and ſlender.

Domicella. White, with numerous deep black tranſverſe bands meeting beneath, and a blackiſh abdominal line. *Coluber Domicella*, abdominal ſcuta 118, ſubcaudal ſcales 60. Linn. *Anguis bioclor elegantiſſimus malabaricus*, Seba.

Length about two feet and a half, diameter half an inch; the head is ſmall, covered with large ſcales; tail rather ſhort and tapering to a point. This is a native of India; it is ſaid the ladies in India ſometimes carry this ſnake in their boſoms, and hence Linnæus named it domicella.

Viridissimus. Bright green; abdomen whitiſh, with the ſcuta dilated towards the middle. *Coluber viridiſſimus*, abdominal ſcuta 217, ſubcaudal ſcales 122.

This beautiful ſnake is a native of Surinam. The length is about three feet; head ſlightly obtuſe, of moderate ſize, covered with very large ſcaly plates; the remainder of the upper parts with ovate ſcales; the tail is of moderate length and ſlender. The green on the back inclines more or leſs to blue or purple in different individuals, and the abdomen in ſome than in others. It is eſteemed a harmleſs ſpecies.

Cursor. Greeniſh, with two dorſal ſtripes of linear white ſpots, and whitiſh ſides and abdomen.—*La Coureſſe*, Cepede. Abdominal ſcuta 185, ſubcaudal ſcales 105.

A ſpecies deſcribed by La Cepede, from a ſpecimen in the Royal Cabinet at Paris. The length is near three feet; the head is covered with large ſcales, the tail of moderate length and gradually tapering to the tip. It is ſaid to be a timid animal, and remarkable for the ſwiftneſs of its motions. This inhabits the iſland of Martinico.

Hickanella. White, ſpeckled above with blue, and variegated with blue on the abdomen. *Serpens bikkanella Americanus*, Seba.

A native of South America, where it frequents houſes, and is very uſeful in deſtroying rats, mice, and other vermin. It is about two feet and a half in length, the thickneſs moderate, head oblong, and covered with large ſcales, tail rather ſhort, and gradually tapering.

Perlatus. Pearl-coloured; head and tail ſea-green, the former marked by a red ſpot. *Serpens ex novo Hiſpania*, a Fabro Lynceo.

This ſnake is about two feet and a half in length, and rather thick, except towards the tail, where it gradually tapers to a ſlender point; the top of the head is covered with ſmall ſcales except about the noſe and between the eyes. It is a native of New Spain.

Platurinus. White, ſpotted with brown, and annulated with broad brown zones. Shaw Gen. Zool.

Deſcribed from a ſpecimen in the muſeum of Dr. William Hunter. It reſembles the common ſnake C. natrix, but the tail is rather more ſlender in proportion; the head is rather large, and covered with large ſcales of a black brown colour, elegantly marked with intervening ſpaces of white; the whole animal is about three feet and a half in length.

Argus. Cheſnut-brow, banded with tranſverſe rows of ocellated red ſpots; beneath yellow. *Coluber argus*, Linn. *Serpens arabica braſſilienſibus iboboboca*, and *Boiguacu dicta*; alias *argus*, Seba.

The argus ſnake is a large and elegant ſpecies, meaſuring, according to Seba, above five feet in length, and being of a moderate thickneſs in proportion. The head is large, flattiſh, covered in front with ſmall ſcales, and ſo very protuberant on each ſide at the hind part, ſo as to appear heart-ſhaped. The ground colour is brown, very beautifully marked from head to tail by numerous tranſverſe rows of round ocellated red ſpots, ſurrounded by a white iris, and an exterior red one; the abdomen beneath is pale yellow; tail moderately ſlender and tapering to a point. It is a native of Arabia, and ſeems to be conſidered as a poiſonous ſpecies.

Ocellatus. Cheſnut-brown, with ocellated brown ſpots, and yellow abdomen. *Serpens guineenſis rariſſima argus dicta*, Seba.

In ſize reſembles the viper; the head is covered with ſmall ſcales; tail tapers to a moderately ſlender tip. This, according to Seba, is a native of Guinea, and is a rare ſpecies.

Chiametla. Blue, the ſcales marked with a white ſpot, body beneath yellow. *Serpens americana chiametla dicta*, Seba.

A beautiful ſpecies about four feet and a half in length, found in the Weſt Indian iſlands.

Zeylonicus. Abdominal ſcuta 180, ſubcaudal ſcales 80. Gmel. Gronov. *Coluber maculis majoribus brunneis*, Boddaert. *Serpens maculata ceylonica*, Seba. *Serpens americanus*, Scheuchz.

Catus. White; the ſcales diſpoſed in fours, black, and thickly crowded into patches. *Coluber catus*, Gmel. *Coronella catus*, Laur. Amph.

A native of America; it is obſerved of this ſnake that it lies in wait, and ſprings upon mice like the cat, whence its name.

Cervinus. White, dotted in the middle with black, and branched with black at each end. Gmel. *Coronella virginica*, Laur. Amph. Inhabits America.

Tessellatus. Above alternately teſſellated with black and brown; beneath black with white unequal ſpots each ſide; head long and ſhielded. Gmel. *Coronella teſſellata*, Laur. Amph.

RUBER. Bright red with the ſpots alternately uniting; beneath white. Gmel. A doubtful ſpecies.

MOLURUS. Abdominal plate 248, ſubcaudal ſcales 59. Gmel.

This kind inhabits South America, and reſembles the Boa tribe, but is diſtinguiſhed by the plates, and large ſcales on the head, as in the coluber genus.

MINERVÆ. Glaucous, with a brown dorſal ſtripe, and three on the head; abdominal ſcuta 238, ſubcaudal ſcales 90. Linn.

Length about eighteen inches; thickneſs exceeding that of a ſwan quill; the colour glaucous, with a broad, longitudinal, brown band down the back, and three longitudinal bands on the heads, two of which paſs through the eyes. The head is oblong, ovate, convex, and ſmooth; the eyes large; tail ſlender, and meaſuring about a third of the whole length. Deſcribed by Linnæus from a ſpecimen in the muſeum Adolphi Friderici brought from the Eaſt Indies.

SCUTATUS. Black; ſcuta extremely broad; tail ſubtriangular. *Coluber ſcutatus*, abdominal ſcuta 190, ſubcaudal ſcales 50. Pallas.

Reſembles the common ſnake, *coluber natrix;* the length is about four feet; colour entirely black, except that the abdomen is marked alternately on each ſide with a row of ſmalliſh ſquare yellowiſh-white ſpots. The principal character conſiſts in the ſcuta being remarkably wide, extending on each ſide in ſuch a manner as to embrace two-thirds of the body. This ſpecies was obſerved by Dr. Pallas about the borders of the river Ural; it is found occaſionally both in the water and on land.

HIPPOCREPIS. Livid, ſpotted with brown, with a reverſed lunulated or horſe-ſhoe mark on the back part of the head. *Coluber hippocrepis*, abdominal ſcuta 232, ſubcaudal ſcales 94. Linn. Muſ. Ad. Fr.. *Natrix hippocrepis*, Laur.

Length about twelve inches; head of moderate ſize, marked by a tranſverſe arched brown band between the eyes, and a larger horſe-ſhoe-ſhaped mark on the back of the head; abdomen pale; tail tapering gradually from the tip. A native of America.

DOMESTICUS. Grey, ſpotted with brown; a bipartite black ſpot between the eyes. *Coluber domeſticus*, abdominal ſcuta 245, ſubcaudal ſcales 94. Linn.

This is a native of Barbary, where it appears to be in ſome degree domeſticated, being very common in the houſes of the inhabitants, where it is kept to deſtroy the ſmaller kind of noxious animals. In its general appearance this ſnake is allied to the laſt-mentioned ſpecies, and like that is perfectly harmleſs.

DUBIUS. Abdominal ſcuta 141, ſubcaudal ſcales 24. Linn. Gron. Muſ. Seba.

EXALBIDUS. Whitiſh with tranſverſe broad ſpots mixed with black and white.

COLUBER EXALBIDUS, abdominal ſcuta 135, ſubcaudal ſcales 42. Gmel. *Coluber exalbidus maculis tranſverſis latiſſimis ex et albo mixtis.*

CAHIRINUS. Grey, with large oval brown ſpots on the back, and ſmall quadrangular notched ſpots on the ſides; beneath ſilky white. *Coluber cabarinus*, abdominal ſcuta 230, ſubcaudal ſcales 82. Forſk. Fn. Arab.

Inhabits Cahira. Length four feet and a half, and the thickneſs that of a finger; the head is flattiſh, ſub-cordated, with two pale oblong ſcales on the crown,

CALAMARIUS. Livid, with tranſverſe brown bands and linear points; beneath teſſelated with brown and white. *Coluber calamarius*, abdominal ſcuta 140, ſubcaudal ſcales 22. Linn.

This is a ſmall ſnake, meaſuring about a ſpan in length, the thickneſs that of a gooſe-quill; colour above livid, ſprinkled with linear duſky ſpots, and marked by ſeveral dark narrow tranſverſe bars; the head is very ſmall, convex, and ovate; the tail ſhort and terminating obtuſely. This ſpecies inhabits America.

CARINATUS. Lead-coloured, with large ovate, porous ſcales; back carinated; abdomen whitiſh. *Coluber carinatus*, abdominal ſcuta 157, ſubcaudal ſcales 115. Linn. Muſ. Ad. Fr.

A large ſpecies, growing to the length of five or ſix feet, and of a moderate thickneſs; tail tapering gradually to a point; tail much carinated, riſing into a ridge on the top; colour deep blueiſh brown, or cinereous, inclining to lead-colour, paler or whitiſh underneath; ſcales very large and marked with numerous impreſſed points as if pierced with pin-holes. This is repreſented as a harmleſs ſpecies; it inhabits North America, and varies in colour.

GETULUS. Blueiſh-black, with linear yellow lines on the ſides and bifid bands on the belly. *Coluber getulus*, abdominal ſcuta 215, ſubcaudal ſcales 44. Linn. D. Garden.

Inhabits Carolina, where it frequents moiſt woods and ſhady places, and preys on lizards. Length about three feet. An elegant ſpecies.

PLICATILIS. Livid, with a ſtripe of duſky brown confluent ſpots on each ſide, the anterior ones ocellated with a white pupil. *Coluber plicatilis*, abdominal ſcuta 131, ſubcaudal ſcales 46. Linn. Amoen. Acad. *Ceraſtes plicatilis*, Laur. Amph. *Serpens baliſalan-boeket*, Seba.

Length from two to three feet; the colour browniſh-yellow or livid, with a duſky and lateral ſtripe of confluent ſpots immediately above the centre, the anterior ones of which have a white dot in the centre. The abdomen is pale, and marked with three or ſometimes four rows of ſmall duſky ſpots. The head is covered in front with large ſcales, ſnout obtuſe; tail thick and rather blunt. The ſpecimen deſcribed by Linnæus meaſured, as above-mentioned, leſs than three feet, that deſcribed by La Cepede, a ſpecimen in the Muſeum of the king of France, was more than ſix feet long, from which it appears this ſnake is of a large ſize when full grown.

BATAEN. Spotted with black and white. Forſk. Fn. Arab.

Deſcribed by Forſkal as a native of Arabia; it is a foot in length and two inches in thickneſs, and is highly poiſonous; the body ſwelling to a great ſize after being bitten by this ſnake.

HANNASCH. Entirely black. Gmel. Inhabits Arabia, a cubit in length, and as thick as a finger.

PURPURASCENS. Abdominal ſcuta 189, ſubcaudal ſcales 122. Gmel.

PICTUS. Abdominal ſcuta 172, ſubcaudal ſcales 142. Gmel. Boddaert.

HAJE. Black, with oblique bands, and ſcales half white. *Coluber haje*, abdominal ſcuta 207, ſubcaudal ſcales 109. Linn.

Firſt deſcribed by Forſkal. This ſnake inhabits Lower Egypt, is of a very large ſize, when irritated lifts up, and ſtretches out its head to bite.

PULLATUS. Bands of the body black with white dots; temples ſnowy with black ſpots; beneath white with black ſpots. *Coluber pullatus*, abdominal ſcuta 217, ſubcaudal ſcales 108. Gmel. A native of Aſia.

CARACARAS. Blue, with the ſcales on the fore-part of the body elongated; thoſe behind rhomboidal, and the neck tranſverſely ſtriated with black, *Coluber caracaras,* abdominal ſcuta 190, ſubcaudal ſcales 125. Linn. *Serpens caracaras braſilienſis ſingularis,* Seba

A ſpecies of moderate ſize, length two feet and a half; the head rather large and oblong; ſnout obtuſe; from behind each eye a black ſtreak; colour pale blue, the poſterior part of the body tinged with roſe colour; the ſcales on the fore parts of the animal are of a narrow lengthened form, and on the hind parts rhomboid; neck and anterior parts elegantly marked by numerous tranſverſe black lines; tail rather long, and gradually tapering to the tip. This ſpecies inhabits Braſil.

STOLATUS. Glaucous, with two whitiſh ſtripes, and quadrangular tranſverſe brown ſpots between. *Coluber ſtolatus,* abdominal ſcuta 143, ſubcaudal ſcales 76. Linn. Laurenti. Seba.

Deſcribed from a ſpecimen in the Muſeum Adolphi Friderici as a poiſonous ſnake, but it appears erroneouſly ſo. This ſpecies inhabits India. It is of the middle ſize, meaſuring from a foot and a half to two feet or more in length. The colour is blueiſh above, with two rather remote white lines down the back, and a continued ſeries of brown, tranſverſe, equidiſtant zones. The abdomen is pale or white, each ſcutum being marked on each ſide by two ſmall ſpecks; the head is covered with large ſcales, pale or blueiſh above, and of moderate ſize; tail rather ſhort and tapering to a point.

AURORA. Orange coloured, with the dorſal band and abdomen yellow. *Coluber aurora,* abdominal ſcuta 179, ſubcaudal ſcales 37. Linn. Muſ. Ad. Fr. *Ceraſtes aurora,* Laur Amph. *Serpens acontias, &c.* Seba.

Length two feet and a half, and of moderate thickneſs in proportion; general colour dull orange, with a broad dorſal line of pale yellow; head rather large and covered with very large ſcales; tail rather ſhort and tapering to an obtuſe point. Inhabits South America.

PALLIDUS. Grey, ſpeckled with brown, and marked with a double, interrupted black line on each ſide. *Coluber pallidus,* abdominal ſcuta 156, ſubcaudal ſcales 96. Linn. Amoen. Acad.

Linnæus deſcribes this as being a foot and a half in length, and the thickneſs of a ſwan-quill, with the back ſlightly angulated each ſide. The head is roundiſh, much thicker than the neck and covered with large ſcales; the ground colour pale variegated with ſcattered grey ſpots and points. Inhabits India.

ORIENTALIS. Abdominal ſcuta 202, ſubcaudal ſcales 96. Gmel. Boddaert. *Vipera vera orientalis,* Seba. Inhabits Eaſtern countries.

OVIVORUS. Abdominal ſcuta 203, ſubcaudal ſcales 73. Gmel. *Guinpuajura,* Piſ. Braſil.

We only know of this ſpecies that the plates and ſcales are as above deſcribed, and that the ſpecies inhabits America.

CENCHOA. Head globoſe; body whitiſh, with tranſverſe rhomboidal brown bands. *Coluber cenchoa,* abdominal ſcuta 210, ſubcaudal ſcales 124. Linn. *Anguis de cencoatl americanus,* Seba.

A long and very ſlender ſpecies growing ſometimes to the length of three or four feet, and yet ſcarcely exceeding the thickneſs of a ſwan-quill. The head is very large and nearly globular, the neck extremely thin; and the tail remarkably long, meaſuring nearly a third part of the whole animal, and gradually tapering to the extremity. The colour is white or yellowiſh, marked throughout the whole upper part from the head to the end of the tail, with numerous tranſverſe rhomboidal bars, or patches of brown, the points of which deſcend on each ſide.

FLAGELLUM. Extremely long, ſlender, and brown; abdomen pale. *Coach-whip ſnake,* Cateſby.

This ſpecies meaſures from four to five feet; or even ſix feet in length, and is remarkably ſlender. Cateſby, who deſcribes this ſnake, ſpeaks of it as an active nimble creature, running very ſwiftly and being perfectly harmleſs, "yet, ſays he, the Indians report, not without gaining many proſelytes to their ſilly belief, that it will by a jerk of its tail, ſeparate a man in two parts." This ſnake is a native of Carolina and Virginia.

AHAETULLA. Bright blue-green and irideſcent; abdomen pale, with a black ſtreak acroſs the eyes. *Coluber ahaetulla,* abdominal ſcuta 163, ſubcaudal ſcales 150. Linn. Amoen Acad. *Natrix ahaetulla.* Laur. Amph. *Serpens ornatiſſima amboinenſis bouguatrora.* Seba. *Long green Borneo ſnake,* Petiver.

The general colour is a bright blue green with a golden gloſs, and highly irideſcent. The length is from three to four feet, and the diameter about three-fourths of an inch; the head is covered above with large ſcales, and the ſnout is ſlightly elongated, though not pointed; the tail is ſomewhat angular, and of conſiderable length. It is an innoxious ſpecies, is found in ſeveral parts of India, and is eſteemed one of the moſt beautiful of the ſerpent race.

AESTIVUS. Blue green, ſlender; ſnout obtuſe; abdomen pale green. *Coluber æſtivus,* abdominal ſcuta 155, ſubcaudal ſcales 144. Gmel. *Green ſnake,* Cateſby.

Long and ſlender, the general length about three feet; the head is obtuſe; colour of the upper parts blue green, ſlightly tinged with purple; tail very long and ſlender. This kind inhabits many parts of North America, where it frequents trees and preys on flies and other inſects. Cateſby, to whom we are indebted for the above particulars, adds, that it is eaſily reclaimed from its natural wildneſs, becoming tame and familiar, and affirms that ſome people carry it in their boſoms.

FILIFORMIS. Very ſlender, black; beneath white. *Coluber filiformis,* abdominal ſcuta 165, ſubcaudal ſcales 158. Linn. Muſ. Ad. Fr. *Natrix filiformis,* Laur.

Length about twelve inches, and thickneſs that of a gooſe-quill; the colour above black, appearing like a broad dorſal ſtripe, beneath white; the head is ovate, twice the diameter of the body, above black and beneath white; tail about one-third the whole length, very ſlender, and ſharp-pointed. A native of India.

TORQUATUS. Black above, beneath red, with a white collar round the neck. Shaw Gen. Zool. *Little black and red ſnake,* Edwards.

A ſmall ſpecies, leſs than an earth-worm; head and upper parts jet black, and gloſſy; the head rather large, and covered with large ſcales; eyes flame-coloured. This is a native of Pennſylvania where it inhabits crevices of rocks, old walls, &c. and feeds on inſects.

SIPEDON. Entirely black or deep brown. *Coluber ſipedon,* abdominal ſcuta 144, ſubcaudal ſcales 73. Linn. A native of North America; deſcribed by Kalm.

DABOYA SNAKE, *Le daboie,* La Cepede.

Deſcribed by La Cepede who conſiders it as the ſpecies which in the kingdom of Juda, and ſome other parts of Africa, is regarded as a deity, and kept in temples conſecrated to its worſhip. This ſuperſtition is ſaid by the traveller, De Marchais, to have ariſen from the following circumſtance; the army of Juda being on the point of yielding to that of Ardra, it happened that a large ſerpent of this ſpecies made its appearance, which the chief prieſt probably knowing it to be innoxious lifted it up in his arms and diſplayed as a kind of miracle, or at leaſt as a propitious omen, perſuaded the army again to rally, by which means a ſignal victory was obtained, and the animal was in conſequence exalted into a divinity. It is ſaid to arrive at a very conſiderable ſize, and is of a whitiſh colour, ornamented on the upper part throughout the whole length by a triple row of large oval rufous patches bordered with black, the head is rather large, and is covered with oval carinated ſcales ſimilar to thoſe on the reſt of the animal. The individual deſcribed by La Cepede was preſerved in the Royal Cabinet, and meaſured three feet five inches in length.

Braſilian Snake, *La braſiliene*, La Cepede.

Length three feet; head and body covered with oval carinated ſcales, ſnout terminated by a large and almoſt perpendicular ſcale rounded at the top, but emarginate at the bottom for the paſſage of the tongue; upper parts of the animal marked with large oval rufous patches bordered with black, and in the intervals between the large patches are ſeveral much ſmaller ones of a duſky colour; fangs very large. This is a native of Braſil, and La Cepede believes may be about ſix feet in length when it has attained its full ſize.

Triangular-headed Snake, *La tête triangulaire*, La Cepede.

Reſembles the common viper in general appearance. The colour is greeniſh, with ſpots of different ſhapes on the head and body, uniting ſo as to form a regular band down the back; abdomen duſky, edged with white. The head is of a more triangular ſhape than uſual, and covered with ſmooth ſcales, as are likewiſe the body. Its total length is two feet. This kind inhabits the iſland of Euſtatia.

Panther Snake, *La tigrée*, La Cepede.

Allied to the laſt; length about eighteen inches; head as in the common viper. Colour of the upper parts whitiſh, rufous, with duſky ſpots bordered with black like thoſe on the ſkin of the panther or leopard. The native country unknown.

The *coluber hydrus*, and *coluber laticaudatus* of Linnæus, are excluded from the above, and will be deſcribed under the article Hydrus, the new genus to which they are referred by Mr. Schneider, and which we think it right to adopt. They are generally diſtinguiſhed from the colubrine tribe by having the body ſlender in front, becoming gradually thicker, ſcaled, and the tail compreſſed. See Hyrdus.

COLUBRARIA *Inſula*, in *Ancient Geography*, an iſland of the Mediterranean ſea, near the Baleares. Pliny ſays that the ſoil engendered ſerpents. It is thought to be the preſent iſle of Formentera, and the ſame with that which the Greeks called Opdiuſa, from ὄφις, *ophis*, *a ſerpent*. It lies S. of Yicca, and was inhabited.

COLUBRINUM *Lignum*. See Lignum Colubrinum.

COLVEND *Copper-Mine*, in *Mineralogy*, Galway county, in Ireland; the ſpecimens of ore found in this mine are very beautiful and deſerving the attention of mineralogiſts and collectors. See Willimes's Mineral Kingdom.

COLVILLE, Cape, in *Geography*, a cape on the eaſt coaſt of New Zealand; lying in S. lat. 36° 26′. E. long. 194° 27′. This cape riſes directly from the ſea, to a conſiderable height, and is remarkable for a lofty rock, which may be diſtinguiſhed at a very great diſtance. From the S. point of this cape the river Thames runs in a direct line S. by E., and is no where leſs than three leagues broad for the diſtance of fourteen leagues above the cape, and there it is contracted into a narrow ſtream, but continues the ſame courſe through a flat country, or broad valley, which lies parallel with the ſea-coaſt. On the eaſt ſide of the broad part of this river the land is tolerably high and hilly; on the weſt ſide it is rather low, but the whole is covered with verdure and wood, and has the appearance of great fertility, though there were in Cook's voyage, Nov. 1769, but a few ſmall ſpots which had been cultivated. Six leagues within cape Colville, under the eaſtern ſhore, are ſeveral ſmall iſlands, which, together with the main, ſeem to form good harbours; and oppoſite to theſe, under the weſtern ſhore, lie other iſlands of which, probably, good harbours may be formed. The river affords good anchorage, and is defended from the ſea by a chain of iſlands, lying acroſs the mouth of it, and on this account called by Cook "Barrier Iſlands;" theſe ſtretch N.W. and S E. 10 leagues. The S. end of the chain lies N.E. between two and three leagues from cape Colville; and the N. end lies N.E. 4½ leagues from Point Rodney. "Point Rodney" lies W.N.W. nine leagues from cape Colville, in S. lat. 36° 15′. W. long. 184° 33′. The natives, reſiding near the river, are not numerous; but they are a ſtrong, well-made, and active people, and all of them paint their bodies with red ochre and oil from head to foot. Their canoes were large and well-built, and adorned with carving.

COLUMB, St. Major, a market town of England, in Cornwall, in the hundred of Pider; 19 miles N.E. of Truro, and 245 W. of London. This town had for ſome years a communication with the ſea-coaſt by means of the Columb canal, but which is now filled up and diſuſed. The Mawgan canal was alſo another abortive attempt at conducting a permanent navigation into this elevated neighbourhood for the conveyance of its China-ſtore and potters' clay to the place of ſhipping.

Columb, *St. Minor*, a village of Cornwall, in the hundred of Pider: the ſituation of its church ſteeple was determined in the Government Trigonometrical Survey in 1796, by obſervations from St. Agne's ſtation, diſtant 58,448 feet, and bearing 44° 7′ 57″ S.W. from the parallel to the meridian of St. Agnes; and from Henſbarrow ſtation diſtant 53,942 feet; whence is deduced its latitude 50° 25′ 21″.0 N. and its longitude 5° 1′ 29.3″ or $20^{m}\ 5^{s}.9$ W. of Greenwich.

COLUMBA, in *Ornithology*, the genus pigeon. Thoſe have the bill ſtraight, and deſcending towards the tip; the noſtrils oblong, and half covered with a ſoft tumid membrane.

The pigeon tribe is divided into two families, the firſt having the tail even at the end, and of moderate length; the other cuneated and long.

* *Section*. Tail of moderate length, and even at the end.

Oenas. Blueiſh; neck above gloſſy-green; double band on the wings and tip of the tail blackiſh. Linn. Fn. Suec. *Oenas*, or *Vinago*, Aldr. Will. *Stock dove*, Arct. Zool. *Holtztaule*, Friſch.

The ſtock dove inhabits Europe and Siberia, frequenting rocky places and ruins in retired ſituations.

Domestica. Cinereous; rump white; band on the wings, and tip of the tail blackiſh. Linn. Fn. Suec. Scopoli. *Columba domeſtica*, Briſſ. *Common pigeon*, Ray, Albin, &c. *White rumped pigeon*, Lath.

The common, or domeſtic pigeon admits of an infinite number of varieties, many of which are remarkable for the beauty and elegance of their plumage; the principal varieties of theſe birds have been minutely regarded by Buffon and ſome other writers, and are enumerated in the following order in the Gmelinian Syſtema Naturæ.

Livia. Stock dove. Wings with a double blackiſh band, called by Buffon *biſet*, and by Albin the *ſtock dove.*

Saxatilis. Rock pigeon. Quill-feathers fuſcous. *Columba rupicola* of Ray.

Hispanica. Roman pigeon. Cere whitiſh and ſcurfy. *Columba romana* of Briſſon. *Columba domeſtica major*, Ray. *Pigeon romain*, Buff. *Greater tame pigeon*, Willughby.

Dasypus. Rough-legged pigeon. Legs rough with feathers. *Rough footed dove*, Willughby. *Rauchfüſige taube*, Friſch.

Cristata. Creſted pigeon. Head creſted; legs hirſute and cinerous. *Pigeon huppé*, Buff.

Norwegica. Norway pigeon. Head creſted; legs hirſute and ſnowy. Briſſ.

Barbarica. Barbary pigeon. Area of the eyes naked and papillous; a double black ſpot on each wing. *Pigeon de barbarie*, Buff. *Barbary pigeon*, Ray.

Cucullata. Jacobine. Feathers of the hind head erect, reflected. *Columba anglica*, or *ruſſica*, Geſn. *Pigeon nonain*, Buff. *Jacobine*, Ray. *Zahme ſchlagtaube*, Friſch.

Hispida. Laced pigeon. Down ſmall, erect, and diſperſed over the back and wings. *Columba criſpa*, Aldr. *Pigeon friſé*, Buff.

Turbita. Turbit pigeon. Feathers on the breaſt recurvate. *Pigeon à cravate*, Buff. *Turbit*, Ray.

Laticauda. Shaker pigeon. Tail erect, many-feathered, and broad. *Pigeon paon*, Buff. *Broad-tailed ſhaker*, Ray. *Pfauentaube*, Friſch.

Gyratrix. Tumbler pigeon. Throws itſelf over and over in flight. *Pigeon culbutant*, Buff. *Tumbler*, Ray. *Tummeltaube*, Friſch.

Galeata. Helmet pigeon. Head and quill-feathers of one colour, and different from that of the body. *Pigeon cuiraſſé*, Buff. *Helmet pigeon*, Ray.

Turcica. Turkiſh pigeon. Cere papillous and red. *Türkiſche taube*, Friſch. *Turkiſh* or *Perſian pigeon*, Willughby.

Tabellaria. Carrier pigeon. Cere broad, carunculated and whitiſh; eye-lids naked. *Carrier pigeon*, Ray, Willughby.

Gutturosa. Cropper pigeon. Breaſt inflated. *Pigeon groſſe gorge*, Buff. *Cropper pigeon*, Ray. *Kropftaube*, Friſch.

Eques. Light-horſeman pigeon. Breaſt inflated; cere carunculated. *Light horſeman pigeon*, Ray.

Percussor. Smiter pigeon. Strikes its wings violently in flight. *Smiter pigeon*, Ray, Willughby.

Jubata. Turner pigeon. Creſt hanging down from the crown like a mane. *Turner pigeon*, Will.

Maculata. Spot pigeon. White tail and frontal ſpot of one colour. *Spot pigeon*, Willughby.

Montana. Orbits naked and red; body rufous, beneath yellow. Linn. *Columba rufa cayennenſis*, Briſſ. *Perdix montana*, Ray. *Mountain partridge*, Sloane, Brown, &c. *Partridge pigeon*, Latham.

This bird, is eight inches and a half in length. The bill is red, with a black tip; the irides red, and ſurrounded with a warty ſkin of the ſame colour; the upper parts of the body are rufous, with a purpliſh hue; the under part of the neck, with the breaſt fleſh colour; belly, ſides, and vent, ſomewhat rufous; under wing-coverts, quills, and tail rufous; legs red, with the claws black. Thoſe birds inhabit Cayenne; they build in trees which have the boughs hanging low, and line their neſts with hair and cotton. They feed on the berries of the myrtle. Dr. Latham ſuſpects, that this ſpecies is found in St. Helena, as a bird is mentioned in Mr. Anderſon's catalogue, under the name of *columba perdix*, and which is ſaid to be very common in that iſland. A kind of pigeon, conceived to be a variety of the above, is deſcribed by Edwards; the forehead is of a clay colour; the head and neck, reddiſh purple; back, wings, and tail, red brown, with a gloſs of copper-colour; the fore part of the neck is reddiſh clay colour; breaſt, belly, thighs, and under tail-coverts, light clay colour; a white mark on each ſide under the eye, and another at the ſide of the throat, and juſt at the joint of each wing.

Tetraoides. Head, and neck black, with white margin. Scop. *Tetraoid pigeon*, Lath.

The only account we have of this bird, is from the work of Scopoli. Ann. 1. p. 125. He informs us it equals the red-legged partridge in ſize, and that the head and neck are black, and encompaſſed with a white margin, as in that bird. The deſcription was taken from a bird living in a menagerie.

Leucocephala. Bluiſh; orbits and crown white. *Columba leucocephala*, Linn. *Columba minor, capite albo*, Ray. *Columba ſaxatilis jamaicenſis, le pigeon de roche de la Jamaique*, Briſſ. *Bald-pate pigeon*, Sloane. *White crowned pigeon*, Arct. Zool.

Breeds in vaſt numbers among the rocks on the coaſts of Jamaica, St. Domingo, and the Bahama iſlands; and ſubſiſts on the berries of the ſweet wood. The length is ten inches and a half; the bill red with a white tip; the eyes ſurrounded with a white ſkin, the irides yellow; crown of the head white, beneath changeable; neck green and blue, varied with a gloſs of copper; the quill, feathers, and tail are brown; the legs red, with grey claws.

Leucoptera. Orbits naked, and blue; tail feather cinereous, with the tips white, the middle ones fuſcous. Linn. *Columba indica*, Briſſ. *Brown Indian dove*, Edwards. *White winged dove*, Brown. Jam.

This bird is the ſame ſize as the common turtle, and meaſures in length eight or nine inches. The bill is duſky black. A fine blue ſkin ſurrounds the eyes, and according to the figure in the plates of Edwards, goes on to the baſe of the upper mandible. The irides are crimſon; the forehead, cheeks, and front of the neck and breaſt, pale rufous brown; hind part of the head and neck dull brown. The upper part of the body is dark brown, with a mixture of blue; greater wing-coverts the ſame, but the outer margins, and tips are white. The two middle tail feathers, are the ſame colour as the back, the reſt dull aſh, with white tips; legs red, with black claws. The white winged dove, inhabits the Eaſt Indies, and is obſerved to flirt up its tail at intervals, like the common wagtail.

Fusca. Fuſcous; eyes black; neck and breaſt white, undulated with black. Jacq. Beytr.

This is the ſize of the turtle, and inhabits Carthagena, in America. Latham conſiders it as a variety of the laſt.

Martinica. Somewhat violaceous; abdomen reddiſh; quill feathers rufous on the inner webs. *Columba martinica*, Linn. *Columba violacea martinica*, Briſſ. *Pigeon violet de la martinique*, Buff. *Martinico pigeon*, Lath.

About the ſize of a turtle; the length nine inches and a quarter; the bill is red, and the eyes are ſurrounded with crimſon tubercles; the head, neck, and upper parts of the body, are cheſnut gloſſed with violet; the under parts of the body, more or leſs rufous; the quills the ſame as the upper, but on the outer edges only, the inner rufous; the tail feathers, the ſame on both margins; legs reddiſh with browniſh claws. Inhabits Martinico. *Le pigeon de la Martinique* of Briſſon, and which Buffon calls *Le pigeon roux de Cayenne*, is conſidered as a variety or rather the female of the above mentioned bird; it is of a reddiſh brown colour, with a collar of golden violet; the wings are ſpotted with black; lateral tail feather black at the end, with the tip white. Inhabits alſo Martinico.

JAMAICENSIS. Purpliſh brown, beneath white; tail feathers blue, terminated by a white line. *Columba jamaicenſis*, Linn. *Pigeon de la Jamaique*, Buff. *Columba minor ventre candido*, Raii. *White bellied pigeon*, Lath. *White bellied dove*, Sloane.

The length of this ſpecies is nine inches. The noſtrils are much elevated, and form two tubercles at the baſe; the top of the head, with the under parts of the neck and body are white; hind part of the neck varied with blue and purple; back, rump, and upper tail-coverts, purpliſh brown, with a light reddiſh tinge. This bird is found in the ſavannas of Jamaica, in the month of January. It feeds on berries, frequents trees, and has a mournful note, which is ſometimes very loud and diſagreeable.

CORONATA. Blueiſh, above cinereous; orbits black; creſt erect; ſhoulders ferruginous. Gmel. *Columba mugiens*, Scop. Ann. *Phaſianus criſtatus indicus*, Briſſ. *Faiſan couronné des Indes*, Buff. *Goura de la nouvelle Guinée*, Sonnerat. *Great crowned Indian pigeon*, Edwards.

The crowned pigeon is nearly the ſize of a turkey, in which particular, it far exceeds any other ſpecies of the ſame tribe. Briſſon has placed it with the pheaſants, and his example is followed in the *planches enluminées*, but the bird poſſeſſes in every reſpect, the manners of the pigeon tribe; its note is cooing and plaintive like thoſe birds, only louder in proportion. We are told, the mournful notes of theſe birds, alarmed the crew of Bougainville very much, when they touched in their voyage at one of the iſlands they inhabit, as they miſtook it at firſt for the cries of the human ſpecies. The crowned pigeon, we are aſſured by Scopoli, has been known to build its neſt and lay eggs in Europe, though the young were not hatched; they made a neſt on trees in the menagerie, where they were kept, compoſed of hay and ſtalks. The female it is obſerved never ſat, but ſtood upon the eggs, and it is ſuppoſed by Scopoli, that it muſt be from this cauſe alone, theſe eggs proved abortive. In the Eaſt Indies, they are occaſionally kept in court yards like other domeſtic poultry.

CRISTATA. Reddiſh brown, creſted; under ſide, head, and neck, black; back and tail green; front with ſix very long, erect feathers. *Columba criſtata*, Gmel. *Le zouloul de Malacca*, Sonnerat. *Uncommon bird from Malacca*, Phil. Tranſ. *Leſſer crowned pigeon*, Lath.

The bill of this ſpecies is conical and rather bent; the colour black, except the under mandible, which is yellow at the baſe. On the fore part of the head, are ſix very long black briſtly hairs, which ſtand upright, and may be depreſſed or elevated by the bird at pleaſure; on the back part of the head, is a creſt of a gilded red colour, compoſed of hard and ſtill feathers, The ſpace between the two creſts is white, forming a band acroſs the head. The eyes are encircled with ſtiff white feathers. The legs are yellow; the toes are ſeparated at their origin, and the hind claw is deſtitute of a claw. Size of the common pigeon. A variety of this bird, formerly in the Leverian Muſeum, meaſured ten inches in length: the bill was yellowiſh, with the tip black; the back part of the head, creſted as in the former; the forehead white, paſſing backwards on each ſide beneath the creſt; the eyes were ſurrounded with feathers of a reddiſh colour, which paſſed backwards in a point; the head and neck were dark reddiſh brown; breaſt, belly, and vent, violet black; wings fine reddiſh brown; back, rump, and tail, dull browniſh green; tail coverts long and falling over the tail; legs reddiſh yellow, with black claws. The hiſtory of this laſt bird is unknown, but it is conſidered as a variety, or perhaps a ſexual difference.

POMPADORA. Green; wings purpliſh, quills black; chin and throat yellow. Gmel. *Pompadour pigeon*, Lath. Gen. Syn. Brown. Illuſtr. *Yellow-faced pigeon*, Brown (fem).

The pompadour pigeon is a native of India, and appears to be moſt common in the iſland of Ceylon. It is conſtantly ſeen on trees, and for the moſt part on thoſe known by the name of *Waringin grothebria*, on the berries of which it delights to feed. They are ſhot by Europeans, who eſteem them excellent eating; the natives take them with bird-lime. The ſize is leſs than that of the common turtle; the back, breaſt, and belly, are pale green; the wing-coverts of a fine pompadour colour; tail green; and legs red. The female is paler, and has the wing-coverts the colour of the body. Thoſe birds are common in the country about Bengal, where they are called *coucla*; it is ſaid to have a whiſtling note, reſembling that of the thruſh.

ERYTHROPTERA. Black; eye-brows, and front white; neck above, ſhoulders and wing-coverts garnet colour; tail from the baſe to the middle cinereous; legs brown.

Length nine inches and a half; tail two inches and a half long and even at the tip; legs brown.

This inhabits the iſland of Eimeo. Another bird much reſembling this, and ſuppoſed to be the female, was met with at Otaheite; the forehead, throat, front of the neck and breaſt, were white, the hind part of the neck duſky; over the eye a ferruginous ſtreak, paſſing a little downwards on each ſide of the neck; the back duſky black; belly duſky; quills and tail blackiſh. Another analogous kind, found in the South Sea iſlands, is of a reddiſh black colour, with the breaſt, and eye-brows white, and the legs red.

ALBICAPILLA. Green; crown hoary; ſides of the neck cheſnut with a golden gloſs; greater quill feathers and tail black. *Columba albicapilla*, Gmel. *Le pigeon vert à tête griſe d'Antique*, Sonnerat. *Grey headed pigeon*, Lath.

A native of the iſle of Panay. Its ſize is equal to that of the common pigeon: the bill dull red with the irides yellow; the leſſer quill feathers are green, with a metallic luſtre, and on the arm-pits is a ſemi-circular ſpot, half grey, and half green; the legs are dull red.

INDICA. Body purple; ſhoulders green; cap blueiſh. *Columba indica*, Linn. *Palumbus amboinenſis*. *Le pigeon ramier d'amboine*, Briſſ. *Green winged pigeon*, Lath.

Size of the turtle; the bill ſcarlet and ten inches in length; noſtrils blueiſh; forehead white, with a ſtreak of the ſame through the eye. The ſides of the head, neck, and breaſt is reddiſh, the hind part deepeſt; upper part of the back and wing-coverts green gold, gloſſed with coppery; ridge of the wing ſpotted with white; lower part of the back, rump, and upper tail-coverts reddiſh brown; quills browniſh, and rufous next the baſe; tail three inches long; two middle tail feathers black; the reſt cinereous, with the tips black; legs red, with black claws. A native of Amboina. Jacquin deſcribes a variety of this bird, having the quills and tail feathers green; wing-coverts violet; and the rump and vent blue.

PURPURATA. Green; cap ſcarlet; vent fulvous; head, neck, and collar white. *Columba purpurata*, Gmel. *Purple-crowned pigeon*, Lath.

A general inhabitant of the iſlands in the Pacific ocean, and ſubject to conſiderable variations in the colour of its plumage. The natives of Tongo Taboo call it *kurukuru*, thoſe of Otaheite Oopa, and Oopara. It lives on the banana, and is eaſily tamed.

JAMBOS. Green; front red; breaſt white. *Columba jambu*, Gmel. *Pooni jamboo*, Marſd. *Jamboo pigeon*, Lath.

Rather ſmaller than the common dove; the bill is yellow, the fore part of the head of a deep pink, reſembling the colour of the bloſſoms of the jamboo, whence its name of jamboo pigeon; the back, wings, and tail are green, with the breaſt and crop white; the eyes are yellow, and from the orbits to the breaſt extends a white ſtreak, edged on one ſide with green, and on the other with pink. This is a native of Java, and feeds chiefly on berries.

RUBRICAPILLA. Violet-black; cap and orbits of the eye naked and red; neck, upper part of the back, and breaſt greyiſh. *Columba atricapilla*, Gmel. *Le pigeon violet à tête rouge d'Antique*, Sonn. *Red crowned pigeon*, Lath.

Found in the iſle of Panay by M. Sonnerat. This bird is the ſize of the jacobin pigeon. The bill is grey. At the baſe of the upper mandible is a fleſhy membrane of a bright red colour entirely encircling the eye; legs grey.

PURPUREA. Green; head and neck purpliſh; breaſt fulvous; vent ſcarlet. *Columba purpurea*, Gmel. *Purple pigeon*, Brown, Lath.

Size of the common wood-pigeon. The front is pale green; breaſt orange; back, ſcapulers, and belly light green; quills duſky. A native of Java where it is called *joan.*

EIMENSIS. Greeniſh brown; front, collar, and beneath vinaceous; crown and neck above brown; double band on the breaſt purple and white. *Columba eimenſis*, Gmel. *Purple breaſted pigeon*, Lath. Inhabits the iſland of Eimeo. Length fourteen inches.

VERNANS. Green, beneath yellow, outer margin of the wing pale yellow. *Columba vernans*, Linn. Gmel. *Le pigeon vert de Philippines*, Buff. *Columba madera ſpatana*, Raii Syn. *Le pigeon vert male de l'iſle de Luçon*, Sonnerat. *Parrot pigeon*, Lath.

Inhabits the iſlands of Manilla and Panay. The female is of a greeniſh-grey, and greeniſh yellow beneath. The ſpecies is rather larger than the turtle.

AROMATICA. Green-olive; back bay-colour; double bar on the wings yellowiſh and black; quill feathers black, with yellow edges. *Columba aromatica*, Gmel. *Columba viridis amboinenſis*, Briſſ. *Pigeon vert d'Amboine*, Buff. *Aromatic pigeon*, Lath.

Size of the common turtle; length ten inches and a half. The bill is greeniſh; crown grey; tail beneath black at the baſe, and at the tip whitiſh; legs grey or red. A native of Amboina.

ST. THOMAE. Green; vent yellow; bill curved, blue, and red at the baſe. *Columba viridis S. Thomæ*, Briſſ. *A wild pigeon from St. Thomas's iſland*, Will. Ray. *St. Thomas's pigeon*, Lath.

The ſize of the common pigeon; the eyes are black, ſurrounded by blue orbits, with the wings and tip of the tail brown. Inhabits the iſland of St. Thomas.

CURVIROSTRA. Green; beneath yellowiſh; vent white; back and ſhoulders bay; wings with two yellow bars; middle tail feathers green; lateral ones cinereous with a black band. *Columba curviroſtra*, Gmel. *Hook billed pigeon*, Lath.

Inhabits the iſle of Tanna in the South Seas; the bird, ſuppoſed to be the female of this ſpecies, differs from the male in having the back and ſhoulders green, and the under tail-coverts, together with the vent white.

TANNENSIS. Green; wing-coverts ſpotted with white; ſecondary quill feathers edged with yellow at the tip. Lath.

Deſcribed from a drawing in the poſſeſſion of ſir Joſeph Banks. The bird is eleven inches in length, and inhabits the iſle of Tanna. This is, perhaps, only a variety of the laſt.

CYANOCEPHALA. Vinaceous-brown; head and throat blue, with a white band between the eyes. *Columba cyanocephala*, Linn, *Turtur jamaicenſis*, Briſſ. *Tourtelle de la Jamaique*, Buff. *Turtle dove from Jamaica*, Albin. *Blue-headed turtle*, Lath.

A native of the iſland of Jamaica, Cuba, and other warm parts of America. Size of the common pigeon.

PACIFICA. Back greeniſh brown; head, neck, breaſt, and abdomen cinereous white; tail blackiſh. *Columba pacifica*, Gmel. *Ferruginous vented pigeon*, Lath.

The length of this ſpecies is thirteen inches and a half; the noſtrils are gibbous, the throat whitiſh; breaſt vinaceous, and the legs either red or brown. It is a native of the Friendly Iſlands. A variety of this ſpecies has the head, neck, breaſt, and belly whitiſh; back, wing-coverts, and tail greeniſh, and the bill gibbous at the baſe. This inhabits Otaheite and Tongataboo.

MEXICANA. Fuſcous, orbits ſcarlet; breaſt and tip of the wings white. *Columba mexicana*, Briſſ. *Pigeon du Mexique*, Buff. *Ceboilolt*, Ray. *Mexican pigeon*, Lath.

A native of Mexico; the irides are black; the legs red.

NAEVIA. Above fuſcous, ſpotted with black; beneath pale fulvous; under tail-coverts, and beneath the wings, cinereous. *Columba naevia*, Gmel. *Oenas mexicana*, Briſſ. *Hoilotl*, Ray. *Black ſpotted pigeon*, Lath.

Inhabits the ſame country as the laſt, and frequents woods; ſize of the common pigeon.

HOILOTL. Rufous purple; leſſer wing-coverts white; bill and legs ſcarlet. *Columba hoilotl*, Gmel. *Columba montana Mexicana*. Briſſ. *Hoilotl*, Ray. *White-ſhouldered pigeon*, Lath. Inhabits the mountainous parts of Mexico.

CAERULEA. Blue; beneath, bill, legs, and wing-coverts red. *Columba caerulea*, Gmel. *Columba caerulea mexicana*, Briſſ. . *Flacahoilotl*, Ray. *Blue pigeon*, Lath.

Size of the domeſtic pigeon; and an inhabitant of Mexico.

PALUMBUS. Cinereous: tail feathers black on the poſterior part; primary quill feathers whitiſh on the outer edge; neck on each ſide white. *Columba palumbus*, Linn. *Le pigeon ramier*, Buff. *Colombo ſaſſaiuolo*, Cetti. *Ringel tauben*, Gunth. *Ring pigeon*, Lath.

Inhabits the woods of Europe and Siberia, and builds its neſts on trees.

ÆNEA. Legs feathered halfway down; beak and legs greeniſh; body braſſy. *Columba ænea*, Linn. *Palumbus moluccenſis*, Briſſ. *Pigeon ramier des moluques*, Buff. *Nutmeg pigeon*, Lath.

Inhabits the Molucca iſlands, and feeds on the nutmeg: its ſize is equal to that of the ring-pigeon. A variety of this ſpecies is deſcribed by Sonnerat, under the title of *Pigeon cuivre mangeur de muſcade*, and which appears to have been found in New Zealand; another variety has been met with at Amſterdam iſland, where it is called *Orooba ya*.

ALBA. Body white; primary quill-feathers and tip of the tail black. *Columba alba*, Gmel. *Le pigeon blanc mangeur de muſcade*, Sonner. Voy. *White nutmeg-pigeon*, Lath.

This bird inhabits New Guinea, and is deſcribed by Sonnerat, who mentions its feeding on nutmegs, obſerving, that it is probably only the outer ſkin which ſerves them for nouriſhment, as the nut itſelf is voided whole, and ſo little altered, that, after paſſing through the organs of digeſtion, it is not rendered leſs fit for vegetation; and hence it happens, that thoſe birds flying from one iſland to another, diſperſe, and ſow the ſeeds of thoſe valuable plants in every part they frequent. A variety of this ſpecies having the tail white inſtead of black.

GUINEA. Orbits naked and rufous; wings ſpotted with triangular ſpots of white; tail-feathers black at the tip. *Columba guinea*, Linn. Gmel. *Pigeon de guinée*, Buff. *Le tourterelle du cap de bon eſpérance*, Sonner. *Triangular ſpotted pigeon*, Edwards, Lath.

Inhabits the rocky parts of Africa, and is in particular common about the Cape of Good Hope. The ſize is that of the wood-pigeon; its bill is brown, irides yellow; head and neck cinereous, upper parts gloſſed with violet and purple; rump and belly white.

CARIBÆA. Blueiſh; abdomen white; head, lower part of the neck, and breaſt purpliſh; tail faſciated tranſverſely with black. *Columba caribæa*, Gmel. *Columba cauda faſcia notata*, Ray. *Ring-tail pigeon*, Lath.

A bird the ſize of the ring-pigeon, and which is found in all the woods of the Caribbee iſlands. It is in great eſteem for food, each bird ſelling for the table at the price of a dollar. In Jamaica it is frequently called the mountain pigeon. A ſuppoſed variety of this bird is deſcribed by Jacquin, which has the tail cuneated, the orbits bare of feathers, and yellowiſh, and the body blueiſh; the tail of the laſt-mentioned bird is as long as the body, and is deſtitute of the black band ſo conſpicuous in the ring-tail pigeon. We conceive this ought ſcarcely to be conſidered as a mere variety.

ZEALANDICA. Red; abdomen white; rump blue; tail black. *Columba novæ ſeelandiæ*, Gmel. *New Zealand pigeon*, Lath.

A native of New Zealand, obſerved by the Engliſh circumnavigators, in Duſky bay, where the inhabitants call it *Hagarrèroo*. The length of this bird is eighteen inches. The bill and irides are red; quill-feathers duſky; vent blueiſh.

BRUNNEA. Cap, neck above, back, and wing-coverts brown; breaſt, neck beneath, and the rump ſhining green. Lath. Inhabits New Zealand; the bill and legs are ſanguineous.

CHALCOPTERA. Brown-cinereous, edged with rufous; front and chin white; a bifid copper-gold band acroſs the wing, and a black one near the tip of the tail. *Columba chalcoptera*, Lath. Ind. Orn. *Bronze-winged pigeon*, Phil. Bot. Bay.

This beautiful bird is a ſpecies recently diſcovered, and was firſt deſcribed by governor Phillips, in his account of Botany bay. It is the ſize of the common wild pigeon, and appears to be found chiefly in Norfolk iſland. The moſt remarkable character of the bird is the rich band of coppery-gold acroſs the wings; a few ſpots of the ſame colour occurs alſo on the leſſer wing-coverts. Its bill and legs are red; quill-feathers brown, beneath rufous; the two middle tail-feathers brown, the reſt pale lead colour.

MADAGASCARIENSIS. Legs feathered; tail violaceous; body blue-black. *Columba madagaſcarienſis*, Linn. *Le founingo*, Buff. *Pigeon ramier bleu de madagaſcar*, Pl. Enl. *Madagaſcar pigeon*, Lath.

The length of this ſpecies is ten inches and a half; its ſize that of the common pigeon. The bill and legs are red; the eyes placed in a bare reddiſh ſkin; the feathers on the neck are narrower than the others, and have a mixture of aſh.

AUSTRALIS. Green; abdomen, vent, and thighs ſpotted; ſhoulders violet. *Columba auſtralis*, Linn. *Palumbus viridis madagaſcarenſis*, Briſſ. *Pigeon ramier verd de madagaſcar*, Buff. *Madagaſcar pigeon*, Lath.

A native of Madagaſcar. Length twelve inches; bill lead colour; eyes and legs ſanguineous; poſterior part of the abdomen and thighs ſpotted with black. Perhaps a variety of the laſt.

FRANCIÆ. Blue; orbits naked; rump and tail red; feathers of the neck long, narrow, and pointed at the end. *Columba franciæ*, Gmel. *Le pigeon hollandais*, Sonnerat. *Hackled pigeon*, Lath.

This bird conſiderably exceeds the ring-pigeon in point of ſize. The bill and irides are crimſon; the feathers of the head, neck, and breaſt are long, narrow, pointed, of compact texture, and with a highly poliſhed ſurface. It inhabits the iſle of France, and is never eaten, the fleſh being reputed poiſonous.

MACULATA. Deep green; body above ſpotted with whitiſh; belly blackiſh; tail black, with the tip ferruginous. *Columba maculata*, Gmel. *Spotted green pigeon*, Lath.

Deſcribed by Dr. Latham from two ſpecimens, one in the collection of general Davies, the other in that of ſir Joſeph Banks. The length is twelve inches. The bill black, with the tip yellow; the general colour is dark green, with a gloſſy ſurface; the head and neck darker than the reſt. The feathers of the neck are long and narrow; every feather of the wings and ſcapulars are marked with a pale cinereous-white, and ſub-triangular ſpot; the quill-feathers are black, with the tip cinereous; the legs are brown, and are covered half way down with downy feathers. The native place of this ſpecies is unknown.

NICOBARICA. Tail white; body black; wings blue; back ſhining green; feathers of the neck long. *Columba nicobarica*, Linn. Gmel. *Pigeon de nincombar*, Buff. *Nicobar pigeon*, Albin.

This is one of the moſt ſplendid of the pigeon tribe. Its ſize is that of the common pigeon; the bill is duſky; the irides hazel; head, neck, breaſt, belly, and thighs, and under tail-coverts dark blueiſh-purple; the feathers on the neck are long and pointed, and with the upper parts of the wings are of the fineſt green colour, gloſſed with the moſt vivid hues of red, blue, copper, or golden. The tail and upper coverts are white; legs reddiſh. The female is diſtinguiſhed by the plumage being leſs brilliant and gloſſy, and in having the pointed feathers of the neck ſhorter than in the male. Thoſe birds inhabit the iſle of Nicobar.

SPECIOSA. Ferruginous; tail blackiſh; neck and breaſt varied with rufous, white, and purple undulations. *Columba ſpecioſa*, Gmel. *Le pigeon ramier de Cayenne*, Buff. *Le ramiret*, Ib. *Scallop-necked pigeon*, Lath.

Rather larger than the common turtle. The bill is red, covered with a white cere; the head ferruginous; neck and breaſt varied with rufous white and purple, each feather being rufous, with a white mark, and the margin blue, gives the whole plumage in this part a beautiful undulated appearance; the back and wings are ferruginous; quills darker than the reſt; tail duſky black, and rounded; the legs red. The female is marked in the ſame manner as the male, but is much duller in colour. A native of Cayenne.

TURTUR. Tail-feathers white at the tip; black grey breaſt fleſh-colour; on each ſide of the neck a patch of black feathers, white at the tip. *Columba turtur*, Linn. *Turtur auritus*, Ray. *Palumbus turtur*, Klein. *Tourterelle*, Buff. *Tortora*, Zinnan. *Common turtle*, Penn.

The turtle is a general inhabitant of Europe, China, and India, and appears to be moſt frequent in Turkey and the ſouthern parts of Ruſſia, and in the rocky country beyond the lake Baikal. In England thoſe birds are not uncommon during the ſummer, but it is only in this ſeaſon that they are obſerved with us, for they arrive late in the ſpring, and depart in autumn. They build on the higheſt trees in thick and deep foreſts, and lay two eggs like the other kinds of pigeons.

It is related by baron de Tott, that this bird is highly favoured in the Turkiſh dominions, where it is extremely plentiful, government allowing a certain rate per cent. on the duty impoſed on corn that thoſe birds may be allowed to feed unmoleſted. A crowd of them conſtantly alight on the veſſels which croſs the port of Conſtantinople, and carry the corn uncovered either to the mills or magazine, and the boat-men never oppoſe them. This permiſſion to feaſt on the grain brings them in great numbers, and familiarizes them to ſuch a degree, that they are ſeen ſtanding on the ſhoulders of the rowers watching for a vacant place where they might fill their crops in turn. The ſame cuſtom is mentioned by Sonnini.

"In the Leverian Muſeum (ſays Dr. Latham) is a bird ſhot in Buckinghamſhire, which differs from the common turtle in having almoſt the whole ſide of the neck black, inſtead of a patch only, and inſtead of each feather being tipped with white, there is a round ſpot of white on each very near the end, giving the ſides of the neck a moſt beautiful appearance." There were three of thoſe elegant birds in the Leverian Muſeum, including the male, female, and young, all which are now preſerved in the London Muſeum. Thoſe we are perſuaded ought rather to be conſidered as a diſtinct ſpecies than a variety of the turtle. Two others, conſidered as varieties of this bird, are the Portugal dove of Albin, and *La tourterelle griſe de l'iſle de luçon* of Sonnerat, the firſt inhabits Portugal, as its name implies, and is of a brown colour, with the ſpot on the ſide of the neck varied with black and white, and the lateral tail feather on the outer ſide tipped with white; the other is diſtinguiſhed principally by having the two middle tail-feathers black, and the lateral ones white. This inhabits Manilla. Beſides the above Dr. Latham deſcribes *La tourterelle brune de la Chine* of Sonnerat as a further variety of this bird in his "Synopſis," but in the "Index Ornithologicus," it is enumerated as a ſpecies under the name of *orientalis*.

ORIENTALIS. Griſeous brown; feathers on the ſides of the neck black, with pale cinereous tips; band on the wings yellow. *Chineſe turtle,* Lath.

A native of China, and of the ſize of the common turtle; the bill and irides are red; head, neck, breaſt, and back dirty browniſh grey, paleſt on the breaſt; wings brown; rump and tail deep cinereous grey; belly and thighs vinous grey; legs red.

ÆGYPTIACA. Teſtaceous-fleſh colour; chin ſpotted; the feathers black, and two lobed, truncated and ferruginous at the tip. Forſk. Fn. Arab.

This bird is deſcribed by Forſkal, who informs us it frequents houſes in Egypt; the bill is black; head violet and fleſh-colour; orbits naked and blueiſh; back cinereous; breaſt violaceous fleſh-colour; belly and thighs whitiſh; wings brown; the two outermoſt tail feathers cinereous at the baſe, black in the middle, and the remainder white; the two next on each ſide cinereous at the baſe, black in the middle, cinereous beneath, and whitiſh at the tips, the fifth on each ſide brown, in the middle pale black, the two middle ones wholly brown; legs fleſh-colour.

SURINAMENSIS. Cinereous, beneath white; chin varied with black and green; bill blue. *Columba ſurinamenſis,* Gmel. *La tourterelle,* Sonnerat. *Surinam turtle,* Lath.

Length ten inches; the bill long and ſlender, of a fine deep blue without, and red within; and the legs red. The ſpecies is thus deſcribed by Fermin, who informs us it is a common bird in Surinam. It lays eggs twice in a year, making its neſt in woods on the higheſt trees; the fleſh is juicy and delicious.

RISORIA. Above yellowiſh, beneath white, with a black creſcent on the back of the neck. *Columba riſoria,* Linn. *Turtur torquatus,* Briſſ. *Turtur indicus,* Aldr. *La tourterelle à collier,* Buff. *Indian turtle,* Albin. *Collared turtle,* Lath.

Exceeds ten inches in length; the female differs from the male in having the colours leſs vivid, and inclining to grey. Inhabits India, and the ſouthern parts of Europe.

La tourterelle griſe de la Chine of Sonnerat is conſidered as a variety of this bird; it is of a brown colour, beneath vinaceous grey; crown grey; black creſcent on the neck, above ſpotted with white; lateral tail-feathers black, ſpotted with white. This kind inhabits China and Madras.

La tourterelle mulet, turtur hybridus of Briſſ. is alſo of this ſpecies; or, at leaſt, a mixed breed between the common and collared turtles. The head, neck, and breaſt are vinaceous; the back dull reddiſh aſh-colour; belly, beneath the wings, and tip of the tail as in the laſt mentioned bird; the quills are brown; legs ſanguineous.

SINICA. Fuſcous, faſciated with black; abdomen ſomewhat ſanguineous; wings and bill black. *Columba ſinica,* Linn. *Turtur ſinenſis ſtriatus,* Briſſ. *Tourterelle rayée de la Chine,* Buff. *Dove* from China, Albin. *Striated turtle,* Lath.

This is a native of China, and is the ſize of the laſt. The bill is blueiſh aſh-colour; the irides white; crown of the head aſh colour; tail paliſh brown; legs red, and claws white.

STRIATA. Orbits and lores white; body cinereous, faſciated with black; beneath rufous. *Columba ſtriata,* Linn. *Turtur indicus ſtriatus,* Briſſ. *Tourterelle rayée des Indes,* Buff. *Barred turtle,* Lath.

Length nine inches and a half; the bill three quarters of an inch long, and of a pale horn colour; the noſtrils pale blue; irides blue grey. The eyes are placed in a bare white ſkin, which paſſes to the noſtrils; forehead, cheeks, and throat pale blue; top of the head and hind head incline to rufous; upper part of the neck, the back, and wing-coverts are browniſh aſh marked with tranſverſe arcuated black bands; ſides of the neck and body blueiſh, croſſed with blue, black, tranſverſe ſlender lines; fore part of the neck, breaſt, belly, and thighs tinged with roſe-colour; under tail-coverts white; legs pale red; claws brown.

This bird is frequent at Malacca and the iſland of St. Helena; and is alſo found, according to Jacquin, in South America.

SURATENSIS. Griſeous; neck above black; hind head white; nape banded with rufous; quill-feathers black; back, rump, and tail obſcure grey. *Columba ſuratenſis,* Gmel. *La tourterelle de Surate,* Sonner.

About ten inches in length. The bill is black; the irides and legs red. It is a native of Surat in the Eaſt Indies.

CAMBAYENSIS. Grey, beneath white; head ſomewhat vinaceous; collar beneath black, varied with rufous; lateral tail-feathers half black and half grey. *Columba cambayenſis,* Gmel. *La tourterelle griſe de Surate,* Sonner. *Cambayan turtle,* Lath.

Deſcribed after Sonnerat as a native of Surat, and other provinces of Cambaya. Its ſize is that of the collared turtle.

VIRIDIS. Braſſy, fore part of the neck purple-violet. *Columba viridis,* Linn. *Turtur viridis amboinenſis,* Briſſ.

Le turvert, Buff. *La tourterelle à gorge pourprée d'amboine*, Pl. Enl. *Green turtle*, Lath.

The length of this bird is ſeven inches and three quarters. The bill is red; fore part of the head and throat aſh-colour; the hind head and back part of the neck, back, rump, upper tail and wing-coverts, breaſt, belly, ſides, and thighs green gold, gloſſed with copper; the greater wing-coverts have the outer edges of the feathers at the tip ſulphur-coloured; under wing-coverts aſh, quills blackiſh; tail blue-green, gloſſed with copper; the legs are red, and covered half their length with feathers; the claws grey-brown. This bird inhabits Amboina.

MALABARICA. Cinereous, beneath white; middle wing-coverts with oval ſpots; lateral tail-feather black two-thirds their length from the baſe, the remaining part white. *Columba malabarica*, Gmel. *Tourterelle de la cote de malabar*, Sonner. *Malabar turtle*, Lath.

A ſpecies the ſize of the laſt, and alſo deſcribed by Sonnerat. It inhabits the coaſt of Malabar. The bill and irides are red; the head, back, and wings are of a pale cinereous-grey; the neck and breaſt grey, tinged with vinaceous; the two middle tail-feathers grey; the belly white; and legs red.

MELANOCEPHALA. Green; head ſomewhat cinereous; head blueiſh-aſh; hind head black; chin and throat yellow; vent orange; ſix middle-tail-feathers green; the outer ones on each ſide fine crimſon. *Columba melanocephala*, Zool. Ind. *Turvert*. Buff. *Tourterelle de Batavia*, Pl. Enl. *Black-capped pigeon*, Ind. Zool.

Found in the iſland of Java. The length is nine inches and a half; the bill black, ſhort, and yellow at the tip; the tail is of a ſomewhat cuneated form; and the legs are black.

JAVANICA. Green; head and neck vinaceous red; abdomen duſky; primary quill-feathers fuſcous. *Columba javanica*, Gmel. *Le turvert*, Buff. *La tourterelle de java*, Buff. Pl. Enl. *Javan turtle*, Lath.

Length nine inches; the bill pale red; covered with a white cere; tail duſky beneath; legs red. Inhabits Java.

CÆRULEOCEPHALA. Green, beneath red; crown blue; wings and tail black-blue. *Columba cæruleocephala*, Lath. *Columba cyanocephala*, Gmel. *Blue-crowned turtle*, Lath. Syn.

Size of the laſt; it is an inhabitant of China, where it is called by the natives *Taupaun*. Common alſo in the iſland of Cuba, where it is caught in traps, and brought to the markets in great numbers as an article of proviſion.

AFRA. Griſeous brown, beneath whitiſh; exterior tail-feathers, at the outer baſe, and the ſpot at the tip white; wing-coverts with violet-azure ſpots. *Columba afra*, Linn. Gmel. *La tourterelle du ſenegal*, Briſſ.

The length of this bird is eight inches. The bill is reddiſh; top of the head aſh-coloured; hind part of the neck, back, wing-coverts, and rump grey-brown; throat whitiſh; fore part of the neck and breaſt pale vinaceous; the belly, ſides, thighs, and under tail-coverts dirty white; the upper tail-coverts are grey-brown, with the tips blackiſh; quills brown, with the inner webs rufous; on the wings are ſome ſpots of green gold-colour, gloſſed with violet; the tail is two inches and three quarters in length; the two middle tail-feathers blackiſh-brown, the reſt grey-brown, with the ends blackiſh; the legs are red, with brown claws. This is a native of Senegal, and is the *Columba ſenegalenſis* of Briſſon, but not of Linnæus; the latter writer deſcribes the next ſpecies under that name.

SENEGALENSIS. Reddiſh-brown, beneath white; neck beneath ſpotted with black; three outer tail-feathers white on the lower half. *Columba ſenegalenſis*, Linn. *Turtur gutture maculato ſenegalenſis*, Briſſ. *Tourterelle à gorge tachetée du ſenegal*, Buff. *Senegal turtle*, Lath.

The length of this ſpecies is nearly ten inches; the bill is blackiſh, the head, neck, and breaſt vinaceous; upper part of the back brown, lower cinereous; the ſix middle feathers cinereous brown; the three others on each ſide dark-aſh from the baſe to the middle, and from thence to the ends white; beneath the colours are half aſh, and half black in the ſix middle feathers, and white in the three outer ones; the legs are red, the claws brown. This bird is found chiefly near the river Senegal.

VINACEA. Grey-brown, beneath white; on the upper part of the neck a black collar; wings fuſcous, with the outer margin of the feathers whitiſh. *Columba vinacea*, Gmel. *Turtur torquatus ſenegalenſis*, Briſſ. *Tourterelle à collier du ſenegal*, Buff. *Collared ſenegal turtle*, Lath.

Size of the laſt, and inhabits the ſame country. The bill is blackiſh; head, neck, and breaſt claret-colour; upper part of the back brown, lower cinereous; belly white; ſix middle tail-feathers aſh-coloured-brown; beneath from the baſe to the middle black, the reſt cinereous.

CRUENTA. Grey; neck beneath white; nape violet; three greyiſh bands acroſs the wings; on the breaſt a ſanguineous ſpot. *Columba cruenta*, Gmel. *La tourterelle griſe enſanglantée*, Sonner. *Red-breaſted turtle*, Lath.

Firſt deſcribed by Sonnerat; it inhabits Manilla. The length of this bird is eight inches; the bill is black; the irides ferruginous; collar on the neck violet, gloſſed with green; the blood-coloured ſpot on the breaſt darkeſt in the middle; wings with three grey and two black tranſverſe bands; quill-feathers black; tail grey at the baſe, and black at the end; legs blackiſh, and ſomewhat violet.

SANGUINEA. Body entirely white; ſpot on the breaſt, the bill and legs ſanguineous. *Columba ſanguinea*, Gmel. *Tourterelle blanche enſanglantée*, Sonner. *Sanguine turtle*, Lath.

This bird inhabits Manilla, and was firſt deſcribed by Sonnerat. It is a ſpecies of great ſingularity, the whole of the plumage being white, except the ſpot on the breaſt, which is of a deep ſanguineous colour; the bill and legs are red, the irides purpliſh.

PASSERINA. Wings and tail duſky; body purpliſh; bill and legs yellow. *Columba paſſerina*, Linn. Gmel. *Turtur parvus americanus*, Briſſ. *Columbus minimus*, Klein. *Turtur indicus*, or *Cocotzin*, Ray. *Cocotzin*, Buff. *Les petites tourterelles*, Pl. Enl. *Ground dove*, Cateſby.

The ground dove is a native of the warmer parts of America, and the contiguous iſlands; and is obſerved as far north as Carolina, but more rarely. Willughby ſays it is very common in Mexico, where it inhabits mountainous places. Bancroft obſerves, that it is the only kind of dove met with at Guiana. In the Caribbee iſlands it is very abundant, and is commonly eaten, being in much eſteem for food; its haunts are ſtony places under buſhes. It is alſo common in Jamaica, where, as Sloane mentions, "they feed on the ground like partridges, and ſpring as they do, riſing and flying for a ſhort flight, and then light again on the ground." They ſubſiſt chiefly on grain and ſeeds of vegetables; and are taken in traps baited with the ſeeds of the *Ricinus*, or wild caſſada.

This is a ſmall and elegant ſpecies, the length about ſix inches. The bill is pale red, with the tip blackiſh; the irides orange; upper part of the head and neck aſh-colour; back, rump, and upper tail-coverts the ſame, but deeper; front vinaceous; throat and breaſt ſpotted with brown; two middle tail-feathers are deep aſh-colour; the others blackiſh;

legs red, the claws blackiſh. The female differs in the general colour of the plumage being paler.

There are ſeveral varieties of this ſpecies, one of which, found at Carthagena in South America, is diſtinguiſhed by having fewer brown ſpots than uſual; another has the body more inclining to reddiſh, and the eyes cheſnut; and a third with the feathers of the neck and breaſt of many colours.

MINUTA. Brown; wings with from five to ſeven ſteel-blue ſpots; outermoſt tail-feathers white at the tip. *Columba minuta*, Linn. *Turtur parvus fuſcus americanus*, Briſſ. *Cocotzin aliud genus, tlapalcocotli*, Will. *Paſſerine turtle*, Lath.

It admits of ſome doubt whether this pigeon is diſtinct from the laſt, C. paſſerina. This kind inhabits America, and is five inches and a half in length. The upper parts of the body are brown, the under more or leſs rufous-white; wing-coverts rufous; two middle tail-feathers brown, the others aſh-coloured at the baſe, black in the middle, and brown at the tip; the bill and legs are black.

MALACCENSIS. Undulated with black lines; above cinereous-grey; beneath cinereous; ſides of the neck white; tail-feathers fuſcous, ſides near the tips white. *Columba malaccenſis*, Gmel. *La petite tourterelle de queda*, Sonner. *Malacca turtle*, Lath.

This is a beautiful ſpecies, ſcarcely exceeding the ſize of the common houſe-ſparrow; the bill is yellow, and in the middle black; the forehead and throat are light cinereous-grey; breaſt and belly vinaceous-grey; middle tail-feathers brown for two-thirds of their length, and from thence to the end white; thighs and under tail-coverts white; legs yellow. This ſpecies inhabits Malacca, and is eſteemed a delicacy for the table.

VERNANS. Green; beneath yellowiſh; outer edges of the wings pale-yellow. *Columba viridis philippinenſis*, Briſ. *Pigeon vert des philippines*, Buff. *Columba vernans*, Gmel.

A native of the Philippine iſlands; the bill and legs are red, the breaſt azure.

Section ** *Tail long and cuneated, or wedge-form.*

MIGRATORIA. Orbits naked and ſanguineous; body cinereous; breaſt rufous. *Columba migratoria*, Linn. Borowſk. *Ænas Americana*, Briſ. *Palumbus caroliniensſis*, Klein. *Pigeon de paſſage*, Buff. *Paſſenger or migratory pigeon*, Phil. Tranſ. Kalm, &c.

Thoſe birds inhabit North America, paſſing the ſummer in the higher latitudes, and retiring to the more ſouthern provinces at the approach of winter. They build in trees, and lay two eggs. It is ſaid thoſe pigeons are ſo abundant in America, that at the period of their migration they are ſeen paſſing from one place to another in flocks of two or three miles in length, and a quarter of a mile in breadth, and which literally darken the air as they proceed. Frequently at ſuch times we are told they alight on trees, and ſometimes in ſuch immenſe numbers as to break down pretty ſtrong branches. They are eſteemed excellent eating, and, during the time of migration, furniſh the common people of America with abundance of food. About Philadelphia they ſhoot theſe birds from the tops of their houſes, or knock them down in the evening from their rooſting places. In Louiſiana they adopt another mode of capture: a party of five or ſix go in the evening into the wood; and taking with them ſeveral diſhes, or other flat veſſels, they ſet brimſtone on fire in theſe under ſuch trees as the birds commonly prefer to rooſt upon, the ſmoke and vapour of which aſcending ſo ſtupefy the birds that they drop down from their reſting places, and are picked up and ſecured in ſacks previouſly provided for that purpoſe. It is ſaid ſuch parties are often accompanied in thoſe nocturnal rambles by the ladies; this mode of taking pigeons being eſteemed a delightful evening's amuſement. The chief food of theſe birds are acorns, rice, corn, and other grain.

The paſſenger, or migratory pigeon of America, is about the ſize of the common domeſtic pigeon of this country. The bill is black, the ſpace round the eyes crimſon; irides orange; head, throat, and hind part of the neck, back, rump, and upper tail-coverts cinereous; wing-coverts the ſame, marked with duſky or black ſpots; the ſides of the neck are gloſſy, variable purple; fore part of the neck vinaceous; belly, ſides, and thighs, with the under tail-coverts, the ſame colour; paler, quills black-brown, edged with white; the tail rather long, with the two middle feathers blackiſh brown, the reſt hoary; legs red, with black claws.

A variety of this ſpecies is deſcribed by Gmelin. The colour is browniſh above, beneath whitiſh-rufous; neck on the forepart ſomewhat vinaceous; lateral tail feathers with a round black ſpot in the middle on the under ſurface.

CAROLINENSIS. Body rufo-cinereous, beneath reddiſh; orbits blue. *Columba carolinenſis*, Linn. *Turtur carolinenſis*, Briſ. *Picacuroba*, Will. *Tourterelle de la Caroline*, Buff. Pl. Enl. *Carolina pigeon*, Arct. Zool. Lath.

Rather larger than the common turtle. The bill is blackiſh; irides black; front, throat, and breaſt rufous, with a green-gold and violet gloſs. The hind part of the head and neck are browniſh aſh; the back, rump, upper tail, and wing-coverts aſh-brown; on the wings, near the tip of the greater coverts, are a few black ſpots; quills blackiſh aſh with whitiſh edges; tail-feathers unequal, the two middle ones four inches and an half in length; the outer ones very ſhort; the two middle ones entirely aſh-coloured brown; the next two on each ſide aſh-coloured, marked with black in the middle, the others light aſh-colour, whitiſh at the end, with a black ſpot between the two colours; the legs are red, the claws black. The female is deſtitute of the gloſſy violet colour on the breaſt. Thoſe birds inhabit Carolina, Braſil, and St. Domingo.

CANADENSIS. Body grey-brown, beneath whitiſh; primary quill feathers yellowiſh at the tip; tail feathers white at the apex. *Columba canadenſis*, Linn. *Tourterelle de Canada*, Buff. *Canada turtle*, Arct. Zool.

Length thirteen inches; the bill blackiſh; upper part of the head, neck, back, and wings grey-brown; the lower part of the back, rump, and upper tail-coverts aſh-coloured; throat and fore part of the neck grey-brown tinged with yellowiſh; wing-coverts marked with blackiſh brown ſpots; tail aſh-coloured, the feathers tipped with white, except the two middle ones; legs red; claws black. In the female moſt of the feathers are tipped with dirty white, which gives the plumage a ſtriated appearance. The native place is Canada.

MARGINATA. Body above fuſcous; beneath brown-grey; breaſt red; tail feathers black at the tip, the edges white. *Columba marginata*, Linn. *Turtur Americanus*, Briſ. *Tourterelle d'Amerique*, Buff. *Long tailed dove*, Edw. *Marginated pigeon*, Lath.

Inhabits America. Length ten inches; the bill is horny; irides rufous; lores white; front and chin reddiſh brown; hind head blueiſh aſh; under the ears a black ſpot; upper part of the body brown; ſhoulders ſpotted with black; throat roſy; two middle tail feathers blackiſh, the reſt cinereous.

AMBOINENSIS. Body rufous; neck waved with black. *Columba amboinenſis*, Linn. *La tourterelle d'Amboine*, Buff. *Amboina turtle*, Lath.

Length fourteen inches; bill black; feathers of the crown, neck, and breaſt with a blackiſh tranſverſe bar near the tip; feathers of the upper part of the back, and wing-coverts brown tipped with rufous; wings brown; tail reddiſh-brown. A native of Amboina.

CAPENSIS. Body grey-brown, beneath white; primary quill feathers rufous on the inſide. *Columba capenſis*, Linn. *La tourterelle*, Buff. *Cape pigeon*, Lath.

Inhabits the ſouthern parts of Africa. The length of this bird is nine inches and a half; the bill is red; body grey-brown; belly whitiſh; ſpot on the wing ſteely; ſecondary quill feathers brown, with the exterior edge grey; tail black beneath; lateral feathers at the baſe grey-brown, with the tips blackiſh; legs red, with the claws black. The female differs in having the throat and fore-part of the neck of the ſame colour as the reſt of the head, and the greater wing-coverts not tipped with black. There are ſeveral varieties of the cape pigeon.

MACROURA. Body cinnamon coloured, beneath whitiſh; tail whitiſh at the tip. *Columba macroura*, Gmel. *Le tourocco*, Buff. *La tourterelle à large queue*, Pl. Enl. *Great tailed pigeon*, Lath.

The length of this bird is twelve inches, the bill red, with a white cere; tail as long as the body; legs red. A native of Senegal.

BANTAMENSIS. Orbits naked and fleſhy coloured; neck, breaſt, and flanks waved with black and white. *Columba bantamenſis*, Muſ. Curſ. f. 3. t. 67.

Common in the iſland of Java. The ſpecies is ſmall, being about the ſize of the wry neck; the bill is black; body above hoary aſh; beneath whitiſh; back, wings, and breaſt with lunate black ſpots; tail ſame length as the body, and conſiſting of fourteen feathers, the ſix middle of which are black, the reſt white towards the tip; legs red.

MELANOPTERA. Body livid or blueiſh; wings black. Molin. Gmel. Deſcribed as a native of Chili. Vide Molin. Hiſt. Chili.

DOMINICENSIS. Body grey; ſides of the head and collar beneath the nape white; ſpot on the crown; band under the eyes, and collar on the neck black. *Tourterelle de St. Domingue*, Pl. Enl. *Columba dominicenſis*, Lath. Ind. Orn.

A native of St. Domingo; the length of this bird is eleven inches; the bill black; wings with a few blackiſh ſpots; breaſt vinaceous; front, chin, and vent white; tail grey; the outermoſt feathers white; legs red.

COLUMBA *groenlandica*, a name given by authors, as Ray, Willughby, and Albin, to the black guillemot. See COLYMBUS *grylle*.

COLUMBA is alſo the name of a military order inſtituted by John I. of Caſtile, about the year 1739.

COLUMBA *Noachi*, a ſmall conſtellation in the ſouthern hemiſphere, conſiſting of ten ſtars. The longitudes, latitudes, &c. of which are given in Sharp's Catalogue.

COLUMBAC denotes that part of the agallochum, which is between the heart, and that part next to the bark.

COLUMBARIA, in *Ancient Geography*, an iſland of the Mediterranean on the coaſt of Etruria, according to Pliny. —Alſo, another iſland of the Mediterranean, near Drapanum in Sicily, called by the Greeks "Pelias."

COLUMBARIUM, a promontory of the iſle of Sardinia, N. of Portu Olbianus, on the E. coaſt: the ſame with *Colymbarium*.

COLUMBATE *of iron*. See COLUMBIUM.

COLUMBIA, in *Geography*, a county of America, in New York, bounded N. by Renſſelaer, S. by Dutcheſs, E. by the ſtate of Maſſachuſetts, and W. by Hudſon river, which divides it from the county of Albany. It is 32 miles long and 21 broad, and is divided into 8 towns, *viz.* of which Hudſon, Claverack, and Kinderkook are the chief. It contained, in 1790, 27,732 inhabitants, and in 1796, 3560 electors.

COLUMBIA, a county of America, in the upper diſtrict of Georgia, bounded by the Savannah river on the E. and N.E., which ſeparates it from the ſtate of Carolina, and N.W. of Richmond county.

COLUMBIA, a townſhip of Waſhington county, in the diſtrict of Maine, on Pleaſant river, adjoining Machios on the N.E., was incorporated in 1796.

COLUMBIA, a poſt-town of America, the capital of Kerſhaw county, and the ſeat of government of S. Carolina. It is ſituated in Camden diſtrict, on the E. ſide of the Congaree river, juſt below the confluence of Saluda and Broad rivers. The ſtreets are regular, and the town contains upwards of 70 houſes. It lies 115 miles N.N.W. of Charleſtown, 35 S.W. of Camden, and 678 S.W. of Philadelphia. N. lat. 34° 1'. W. long 81° 5'.

COLUMBIA, a flouriſhing town of Goochland county in the ſtate of Virginia, on the ſide of James river, near its junction with the Rivanne, 45 miles from Richmond, and 35 miles from Charlotteville.

COLUMBIA, a town of America, in the county of Lancaſter and ſtate of Pennſylvania, ſeated on the N.E. bank of the Suſquehanna river, 10 miles from Lancaſter, and 76 W. by N. from Philadelphia.

COLUMBIA, a town of America, in the county of Hamilton and ſtate of Ohio, ſeated at the confluence of the Little Miami with the Ohio, 6 miles above Cincinnati. The ſettlement began in 1789. N. lat. 39° 20'.

COLUMBIA *College*. See COLLEGE.

COLUMBIA, *territory of*. See WASHINGTON.

COLUMBIANA, a county of America, in the ſtate of Ohio, bounded N. on the county of Trumbull, S. on Jefferſon and Muſkingum counties, E. on the ſtate of Pennſylvania, and the Ohio, and W. on Muſkingum river, and county.

COLUMBIC ACID, in *Chemiſtry*. See COLUMBIUM.

COLUMBIERS, in *Geography*, a town of France, in the department of the Aveiron, and diſtrict of Rhodes; 10 miles W. of it.

COLUMBINA, a name given by Actuarius, and ſome other medical writers, to the verbena, or common vervain.

COLUMBINA *Marga*. See MARLE.

COLUMBINE, in *Botany*. See AQUILEGIA.

COLUMBINE *feathered*. See THALICTRUM *aquilegifolium*.

COLUMBINE, a kind of violet-colour, called alſo dove-colour. See DYEING.

COLUMBIUM, in *Chemiſtry*, a new metal diſcovered by Mr. Hatchett, in the year 1802, in a mineral which he had from the Britiſh Muſeum. The mineral, it appears, had been ſent with ſome ſpecimens of iron ores from Maſſachuſetts in America, to ſir Hans Sloane, in whoſe catalogue it is deſcribed as "a very heavy black ſtone, with golden ſtreaks." By Mr. Hatchett it is deſcribed as of a dark browniſh grey externally, and more inclining to an iron grey internally; he found the longitudinal fracture lamellated; and the croſs fracture had a fine grain. Its luſtre is vitreous, ſlightly inclining in ſome parts to metallic, moderately hard, and very brittle. The colour of the powder was dark chocolate brown; but the ſtreaks were yellow mica. The particles were not attracted by the magnet. Its ſpecific gravity, at the temperature of 65°, was 5.918. A ſeries of very accurate experiments made by Mr. Hatchett proves that this ore conſiſts of iron combined with a new metallic acid: of 200 grains of the ore 42 were found to be the oxyd of iron, and 155 of acid. The mode which Mr. H. adopted to analyſe this columbate of iron was this: he took one part of the ore reduced to powder, and mixed it with five times its weight of carbonate of potaſh, and fuſed them in a ſilver crucible. An efferveſcence took place, which being ſubſided, the whole was poured into a proper veſſel, and ſuffered to cool. Boiling diſtilled water was then poured upon it, and the whole was transferred upon a filter. The inſoluble reſiduum was repeatedly waſhed in diſtilled water. The filtered fluid was now ſuperſaturated with nitric acid. The reſult of which was a white flacculent precipitate, which he denominated *columbic* acid. The inſoluble reſidue was again fuſed with carbonate of potaſh, and treated as before, but ſcarcely any effect was produced, the alkali was therefore waſhed away, and the powder digeſted with muriatic acid, in order to get rid of the iron. The acid was then decanted, and the reſiduum waſhed in diſtilled water. It was again fuſed with carbonate of potaſh, diſſolved, and precipitated with nitric acid. The reſiduum was repeatedly treated in a ſimilar manner, till the whole was completely decompoſed. By theſe means he obtained a precipitate of oxyd of iron which combined with the muriatic acid. The columbic acid is of a pure white colour, but not very heavy, and has ſcarcely any perceptible taſte; it is not ſoluble in boiling water. When ſome of the powder is placed upon litmus paper, moiſtened with diſtilled water, the paper in a few minutes becomes red. When expoſed to the blow-pipe, it is not fuſible, but only becomes of a leſs brilliant white. Having found that this acid poſſeſſed properties different from all other acids, and that the baſe was metallic, Mr. H. gave to the metal the name of *columbium*. In the attempts which he made by heat to reduce it to the metallic ſtate, the oxyd was found only in a ſtate of black powder. From his experiments he found that the metal combines with oxygen in different proportions, and theſe oxyds are diſtinguiſhed by different colours. It combines with ſome of the acids, and forms ſalts; thus we have the ſulphate, muriate, &c. of columbium.

Sulphate of Columbium. Boiling ſulphuric acid forms a tranſparent colourleſs ſolution with columbic acid. When water is added to this ſolution, it becomes turbid, aſſuming a milky appearance; and a white precipitate is gradually depoſited, which cracks as it becomes dry upon the filter, and from white it changes to a lavender blue colour; and when completely dry, to a browniſh grey. It is then inſoluble in water, is ſemitranſparent, and breaks with a vitreous fracture. This precipitate obtained from the ſulphuric ſolution, by the addition of water, is a ſulphate of columbium.

Muriate of Columbium. Columbic acid, when recently ſeparated from potaſh is ſoluble in boiling muriatic acid. This ſolution may be conſiderably diluted with water, without any change being produced. When evaporated to dryneſs, it left a pale yellow ſubſtance, inſoluble in water, and which is diſſolved with great difficulty, when it is again digeſted with muriatic acid.

Phoſphate of Columbium. A few drops of phoſphoric acid being added to a part of the ſolution of columbium in concentrated ſuſphuric acid, at the end of 12 hours converted the whole into a white, opaque, ſtiff jelly, which was inſoluble in water. When a ſmall quantity of phoſporic acid was added to the muriatic ſolution of columbium, in a few hours a white flocculent precipitate was formed. Philoſoph. Tranſ. 1802, part i.

COLUMBO, in *Geography*, the capital of the iſland of Ceylon, and the ſeat of government, is ſituated towards the S.W. part of the iſland, in about 7° N. lat. and 78° E. long. from London. It was captured from the Dutch by the Britiſh troops under general Stewart in 1796. Although Trincomater, on account of its ſituation and harbour, be of greater conſequence to the Britiſh nation to retain, yet Columbo is in every reſpect greatly ſuperior. The number of its inhabitants is much greater; its fort and black town are much larger; the country in which it is ſituated much more fertile; and the rich diſtrict depending upon it much wider, being not leſs than 20 leagues in length and 10 in breadth. Columbo is commonly ſuppoſed to have been firſt fortified by the Portugueſe; but captain Percival queſtions the truth of this ſtatement, as Laurence de Almeyda, after his firſt treaty with the king of the iſland, found that the Moors and Malabars had a fortreſs here, on which ſome guns were planted, which had been procured from ſhips wrecked on this coaſt. That part of the fort, where theſe ancient works ſtood, is now ſtrongly fortified, and ſhewn as the firſt works of the Portugueſe. It is in a manner detached from the main body of the fort, being ſeparated from it by an entrenchment and wall, with a foſſe or ditch, now almoſt choaked up. The fort is placed on a peninſula projecting into the ſea, and it is thus expoſed on all ſides to the ſea-breezes, by which the air is rendered temperate and healthy, though it lies ſo very near the equator. This fort is upwards of a mile in circumference; and is indebted for its ſtrength both to nature and art. On the ſouth ſide the ſurf runs ſo high, and the ſhore is ſo rocky, that it would be dangerous to approach it. On the weſt ſide of the bay, where the ſea is ſmoother, and near the wharf or landing place, which at all ſeaſons of the year is ſafe for boats, the only attempt could be made; but theſe quarters are ſo well defended by the batteries which command the harbour, that there is hardly any probability of its ſucceeding. On the weſt ſide of the fort, and facing the ſea, are two very fine batteries, *en barbet*, intended for the ſecurity of the harbour. Theſe ſtand on a part that projects a conſiderable way from the main body of the fort, from which they are ſeparated by a high wall and ditch flanked with baſtions, and have gates that communicate with the interior of the fort. Here the wharf or landing place is found; it conſiſts of large piles of timber, extending ſeveral yards into the ſea, and affords a very commodious ſtation for loading and unloading ſloops and large boats, which may be brought cloſe alongſide. At this end ſeveral ſtore-houſes, and barracks for half a regiment are erected. The ramparts of the fort are very ſtrong, having eight principal baſtions; and they have alſo a number of leſſer ones, with curtains, banquets, and parapets, communicating with each other all round the fort, and fitted for troops to line and defend with muſketry and field-pieces. The whole fort is ſurrounded by a road and deep oval ditch, over which draw-bridges are thrown at each of the gates. On the outſides are ſome ſmall magazines, with a powder-mill and a ſaw-mill attached to the fort. Adjoining to the covert-way, and at the foot of the plain, is a lake extending three or four miles into the country, in a N. E. direction. For near a mile on the outſide of the fort, the neck of land which connects it with the country, is not above five or ſix hundred yards broad; and in the middle of this ſpace lies the lake, leaving room on each ſide only for a narrow cauſeway. Near the plain an approach might be entirely cut off, by opening the ſluices and cutting the road acroſs, where the lake would be connected with the ſea, and the garriſon completely inſulated. In the centre of the lake is an iſland, communicating with a ſally-a ſally-port on the eaſt face, by a narrow cauſeway and draw-bridges. This is a pleaſant ſpot, abounding with cocoa-nut trees, and was called by the Dutch "Slave Iſland," as it was the place whither they ſent their ſick ſlaves. A battalion of Malays is ſtationed here. This iſland is very convenient, as it lies contiguous to the fort, and opens the neareſt way to the cinnamon gardens, which are cloſe by it. The fort has three gates; the principal one, where the main-guard is ſtationed, which is called the Delph-gate, and leads into the "pettah," or black town. It has two draw-bridges to paſs over the ditch, which here forms an angle. At each of the gates are guard-houſes, with a ſubaltern's guard placed over them.

The plan of Columbo is regular. It is nearly divided into four equal quarters, by two principal ſtreets, which croſs each other, and extend the whole length of the town. To theſe ſmaller ones run parallel, with connecting lanes between them. At the foot of the ramparts, in the inſide, is a broad ſtreet or way, which goes round the whole fort, and communicates with the baſtions and ſoldiers' barracks; and alſo affords, at the different angles, open ſpaces for their private parading. The grand parade is by no means ſufficient for the garriſon, as it can hardly contain one complete regiment. On one ſide of it are ranges of public offices for the civil and military departments, with the town or ſtadt-houſe in the centre of them, where the Dutch held their high court of juſtice. On the arrival of the Britiſh troops they found a rack, wheel, and many other implements of torture, which had been uſed for inflicting puniſhment on criminals, particularly ſlaves, but theſe ſavage modes of puniſhment were immediately aboliſhed by the Britiſh government. On the other ſide of the grand parade ſtand the cinnamon ſtore-houſes, or "go-downs," as they are here called. At the upper end of the parade the Dutch had begun to erect a church, which has never been finiſhed. The Dutch uſually attended divine ſervice at a ſpacious and handſome church in the black town, about a mile diſtant from the fort; and worſhip is ſtill performed there for the Engliſh, either before or after that of the Dutch inhabitants. The government houſe, which faces the harbour, is a very long and capacious building, but more convenient than elegant: ſeveral offices are attached to it, where the buſineſs of government is tranſacted. Behind it is an excellent garden, intended for a "tank" or reſervoir, in caſe of a ſiege; for though every houſe has a well plentifully ſupplied with water through the year, yet it is of a brackiſh quality, and not fit to drink. The Europeans, therefore, both of the civil and military eſtabliſhment, are ſupplied with water from a ſpring, about a mile from the fort, which is brought by means of bullocks, in leathern bags, called here "puckally bags," a certain number of which is attached to every regiment and garriſon in India.

Columbo is built more in the European ſtyle than any other garriſon in India. The interior of the fort has alſo more the appearance of a regular town; the Dutch houſes are all regularly built, though few are above one ſtory high; and the windows have all glaſs-panes, after the European manner. Before each houſe, and connected with it, is a large open ſpace, roofed in and ſupported on pillars of wood, called a "viranda," affording a ſhade from the ſun, and expoſed to the refreſhing breeze of the ſea. The houſes are alſo agreeably ſhaded by a double row of thick-ſpreading trees, planted on each ſide of the ſeveral ſtreets. The walls of the houſes are plaſtered over and white-waſhed with a very fine bright lime, made of burnt ſhells. This beautifully white colour may contribute to the coolneſs of the houſes, but it throws an inſupportable glare on the eyes of the paſſengers along the ſtreets. The houſes are for the moſt part uniformly conſtructed, conſiſting of the hall in the front, with a chamber at each ſide, and another room in the back part, equal in length to the other three, and called the "back viranda." Behind this are one or two ranges of ſmall buildings, proportioned to the ſize of the houſe and deſigned for the accommodation of ſervants, for cellars, and ſometimes for ſleeping rooms. The houſes are covered with indented tiles, which afford no ſecurity againſt rain. In the centre of the principal ſtreet is a very handſome and lofty houſe, which belonged to the Dutch governor, and has ſince been occupied by the commander of the Britiſh forces on the iſland. There is alſo another very handſome and ſpacious houſe for the commandant of the garriſon, with ſuitable offices and gardens. The hoſpital, deſigned for ſoldiers and ſailors, is a roomy and convenient building. Three or four battalions are uſually ſtationed as a garriſon in the fort of Columbo.

The harbour of Columbo, which lies on the weſt ſide, is an open road, affording good and ſafe anchorage to ſhips for only four months of the year, from December to April, when the N.W. winds do not prevail to any great degree; but about May, when the monſoon ſets in on the Malabar coaſt, and extends its ravages to the W. coaſt of Ceylon, the roads of Columbo no longer afford any protection. Hence it is, that Columbo is cut off from any intercourſe by ſea, with the other parts of the iſland, for two thirds of the year. For ſix months of the ſtormy ſeaſon, this ſide of the iſland is ſubject to very heavy falls of rain, accompanied with dreadful thunder and lightning, and violent winds blowing in there. During this ſeaſon the variations of the climate are very great. The heavy rains, predominating moſt by night, render the air damp and chill; and the exceſſive heat of the ſun by day is almoſt inſupportable. Theſe tranſitions make the climate more unhealthy at this ſeaſon than during the hot weather. During the rainy ſeaſon, the Indians from the continent are very ſubject to fluxes, dyſenteries, and fevers. They are alſo ſubject to another very extraordinary diſeaſe, called the "Berry berry," occaſioned by low diet and hard water, which ſwells the body and legs of the patient to an enormous ſize, and generally carries him off in twenty-four hours. The cure is effected by rubbing the diſeaſed perſon all over with cow-dung, oil, chinam, lime-juice, and other preparations from herbs, and then burying him up to the chin in hot ſand. The Britiſh ſoldiers counteract the bad effects of the air and water, by drinking plentifully of arrack and ſmoking tobacco. The "Pittah," or black town, of Columbo deſerves particular notice, on account of its extent and ſuperior ſtructure, compared with other ſuch towns attached to the forts of India. It is divided into two parts; that neareſt the fort conſiſts of one very large ſtreet, beginning at the eſplanade near the walls, and running on till ſtopped by an old mud wall, and a gate called the "Kenman's port." In this diviſion of the Pittah are moſt excellent houſes, where many Dutch gentlemen and merchants reſide. Through Kenman's port there is a narrow paſſage leading into the other diviſion, which conſiſts of a long ſtraggling town, ſkirted on one ſide by the lake above deſcribed. Beſides a principal ſtreet, there are ſeveral ſmaller ones running parallel to it, in one of which is a large well-conſtructed building, called the "Orphan ſeminary, or ſchool," where the Dutch uſed to educate the children of their ſoldiers and the poorer Europeans, as well as thoſe they had by the native women. Here the boys were educated at the public expence, till they were fit for trades; and the females were either ſettled in ſome comfortable ſituation, or married to perſons of their own rank. This laudable inſtitution is ſtill maintained by the Britiſh government. Cloſe by the eſplanade, and adjoining the black town, is the burial ground of the garriſon. The ſhops, bazars, and ſtalls, placed all along the ſtreets, are repleniſhed with various articles of merchandize, peculiarly in uſe among the natives of India; and the town, during the whole day, ſwarms with people of all deſcriptions. The boats or canoes uſed in the fiſheries of Columbo are of a curious ſhape and conſtruction. They are about fifteen feet long, and not more than two in breadth. They move with great ſpeed, eſpecially with the addition of a very large ſquare ſail; and, to prevent their overſetting, a log of wood is extended five or ſix feet from the end of the boat, by way of out-rigger; this log is faſtened to the boat by two long and bent poles, and ſeems to ſerve at once for helm and ballaſt. A paddle, ſomewhat in the form of a ſhovel, is uſed to guide the boat's head. The body of the canoe is a large tree, hollowed out by fire, or ſcooped out by the carpenters. Along its ſides boards are nailed to the height of about two feet, and in the form of a gun-wale, to prevent the water from getting in. When large burdens are to be carried inland by the canals or rivers, two or three of theſe canoes are laſhed together without the out-riggers. Split canoes, bamboes, or betel tree, are then laid acroſs them, ſo as to form a kind of raft; which, though ever ſo much loaded, will draw but very little water. Other flat-bottomed boats of a much greater breadth are alſo uſed by the natives. Theſe are thatched with cocoa-tree leaves, like a houſe, and are large enough to hold couches. Near Columbo may be ſeen two or three hundred of theſe boats in regular rows, moored along the banks of the rivers, with entire families on board, who make them their habitations.

Columbo, for its ſize, is one of the moſt populous places in India; and its population conſiſts of a great variety of nations. Beſides Europeans and Cingleſe, the proper natives of the iſland, you meet, ſcattered over the town, almoſt every race of Aſiatics; Moors of every claſs, Malabars, Travancorians, Malays, Hindoos, Gentoos, Chineſe, Perſians, Arabians, Turks, Maldivians, Javians, and natives of all the Aſiatic iſles; Perſees, or worſhippers of fire, who would rather have their houſes burnt, and themſelves periſh in the flames, than employ any means to extinguiſh it. Here are alſo a number of Africans, Caffrees, Buganeſe, or a mixed race of Africans and Aſiatics; beſides the half-caſts, people of colour, and other races which proceed from a mixture of the original ones. Each of theſe different claſſes of people has its own manners, cuſtoms and language. The language moſt generally ſpoken by both the Europeans and Aſiatics, who reſort to Columbo is the Portuguſe of India, a baſe, corrupt dialect, altogether different from that ſpoken in Portugal.

Columbo, though difficult of acceſs, is ſituated in a rich diſtrict, and furniſhes a great variety of articles to commerce; and, therefore, it is much frequented both by Europeans and the natives of the different coaſts of India. From this diſtrict large quantities of cinnamon and pepper, the ſtaple ſpices of the iſland, are yearly tranſported to Europe in veſſels that touch here on their voyage from Madras and Bengal. A great quantity of arrack is made in the neighbourhood of Columbo and the other diſtricts along the weſt coaſt. A large quantity of Coya-rope, or cordage is alſo manufactured here, for the ſupply of our ſhips on the various ſtations in thoſe ſeas. The inferior articles, exported by the Moors and Malabars, who reſide here for that purpoſe, are betel-leaf and arecca-nut, jaggory, or a ſort of coarſe blackiſh ſugar, cocoa-nut, and oil, honey, bees-wax, cardamoms, coral, ivory, fruit, and a variety of other ſmaller articles. In return they import coarſe woollen cloths, and calicoes, pieces of printed or painted clothe for women's apparel, coarſe muſlins, handkerchiefs, palampores, ſtockings, china-ware, tin, copper, and a variety of toys; alſo bomelves, a ſpecies of fiſh peculiar to Bombay, and onions, from the ſame place, where they are remarkably good. Every year, generally towards February, a Portugueſe or Chineſe ſhip arrives from Macao with teas, ſugar, candied ſweetmeats, hams, ſilks, velvets, nankeens, umbrellas, ſtraw-hats, all kinds of china-ware and toys; all which articles find a very ready ſale, and are paid for in hard caſh. The current coin at Columbo, as well as in the other European dominions on the iſland, conſiſted, on the arrival of the Engliſh, of rix-dollars, a nominal coin, like one pound ſterling, valued at a certain quantity of copper money. There were beſides ſeveral ſmall copper coins, called pice or ſtivers, half-pice, and dudies. Four pice or two dudies made a fanam, and ſeven fanams were equal to a rix-dollar. New regulations have been adopted with regard to the coin ſince the iſland has belonged to the Engliſh. There is now current a new coinage of double and ſingle pice and half-pice made by our Eaſt India Company. A pice is about a halfpenny ſterling; four pice are equal to a fanam, and twelve fanams to a rix-dollar, or, as it is uſually called by our people, a copper rupee. This latter coin paſſes for about two ſhillings ſterling; and four of theſe are equivalent to a ſtar pagoda, a Madras gold coin worth eight ſhillings ſterling, the fluctuation in the value of money in Ceylon is very great, and depends upon the plenty and ſcarcity of gold and ſilver there. The expence of coining at Columbo is more conſiderable than on the continent of India. Horſes and ſervants are particularly expenſive, vegetables are extremely ſcarce, and they form a great article of food in thoſe warm climates. Such articles, however, as are the native produce of the iſland, are found in great abundance, and at a moderate price. Beef, fiſh, and fowl, in particular, are both cheap and plentiful. Mutton is exceſſively dear, as no ſheep can be reared in the neighbourhood of Columbo, which ſome attribute to the noxiouſneſs of the climate or paſture of the iſland, but which may be principally owing to their falling an eaſy prey to jackals, ſnakes, and other deſtructive animals, and alſo to certain poiſonous herbs that occur in many places. Pigs and ducks are plentiful and cheap. Geeſe are rare, and turkeys are not to be had, except occaſionally by importation from other parts of India.

The country round Columbo for ſeveral miles is flat and very rich. It is diverſified with fields of rice and paſture, as well as a variety of groves, in which the cocoa-tree is conſpicuous. The ſcene is embelliſhed by a number of ſmall rivers, lakes, and canals. The ſhady roads, which every where interſect the country, afford to the traveller an agreeable ſhelter; while the numerous country ſeats and gardens which ſkirt them preſent his eye with a continual change of gratification. The river Mutwal extends itſelf here into a very broad channel, and by its numerous windings affords a moſt enchanting proſpect from the road, which runs along its banks for many miles. Several temples of the natives are ſituated along the banks of this river and among the adjoining groves. One of the chief beauties in the vicinity of Columbo is the immenſe number of cinnamon trees, which produce the niceties of the iſland. In the woods they grow wild in abundance, and in the gardens they are now regularly cultivated with the greateſt ſucceſs. Percival's Account of the Iſland of Ceylon, 1805.

Columbo, in the *Materia Medica*. This root was firſt brought from the town of Columbo, in the iſland of Ceylon, in which country it had long been uſed as a valuable remedy in bilious fevers, and other diſorders of the ſtomach and bowels. Our practitioners in the Eaſt Indies adopted the uſe of this root from them, and it is now deſervedly in high reputation in moſt parts of Europe. The plant that yields it is not commonly known.

Columbo root comes to us in circular pieces about two inches in diameter, covered with a thick wrinkled bark of a dark brown externally, but a light yellow within. On paring off this bark the root is ſeen to conſiſt of three diſtinct lamina. The whole is uſed indiſcriminately in medicine.

Columbo root has an aromatic ſmell; the taſte is bitter and nauſeous. It gives no eſſential oil when diſtilled with water, and contains ſcarcely any volatile aromatic parts. When boiling water is poured on the powdered root a ſtrong infuſion is produced, which poſſeſſes all the ſenſible qualities and virtues of the plant, but it grows mouldy in a day or two. Spirit of wine alſo extracts the active qualities of this root very readily.

Columbo is employed with nearly equal advantage in ſubſtance in ſpirituous tincture or in watery infuſion, and generally with the addition of cinnamon or ſome grateful aromatic. This root is of ſingular efficacy in ſtrengthening the fibres of the ſtomach and bowels, either in chronic caſes, or more particularly in cholera morbus, dyſentery, and other violent diſorders of the alimentary canal, where, after due evacuations, it may be employed with great ſucceſs in checking the inceſſant vomiting action of the bowels that bring down the powers of life with ſuch rapidity.

An extract and a tincture of Columbo are kept in the ſhops, the latter of which is by itſelf a very uſeful ſtomachic taken daily in very ſmall doſes.

COLUMBUS, Christopher, in *Biography*, a ſubject of the republic of Genoa, celebrated in hiſtory as the diſcoverer of America. Neither the exact time nor place of his birth can be aſcertained with any degree of certainty, but it is generally ſuppoſed that he was born in ſome part of the Genoeſe dominions about the year 1447. He is ſaid to have deſcended from an honourable family, reduced by various misfortunes to a ſtate of indigence. In whatever rank of ſociety his parents moved, it is certain that they gave their ſon an education adapted to the bent of his genius; at ſchool he acquired the elements of the Latin language, and made ſome proficiency in geometry and the other ſciences which he was enabled in the future part of his life, to apply to the practical parts of navigation. At the age of fourteen he went to ſea, and though his firſt voyages were confined to the Mediterranean, yet he very ſoon ventured out on the northern ſeas, and viſited the coaſts of Iceland, to which the Engliſh and other nations reſorted on account of its fiſhery. About the year 1467 he entered into the ſervice of a ſea captain of his own name and family, and ſpent ſome years in a predatory warfare againſt the Mahometans and Venetians the rivals of his country in trade. In this ſituation he continued acquiring both wealth and reputation, till at length in an obſtinate engagement with ſome Venetian veſſels, off the coaſt of Portugal, the ſhip in which he ſerved took fire, and he, with difficulty, preſerved his life by throwing himſelf into the ſea, and ſwimming a diſtance of two leagues to the ſhore. As ſoon as he had recovered ſtrength for the journey he repaired to Liſbon, where his brother Bartholomew had ſettled, and where he found many of his countrymen, who, like himſelf, had embarked in the ſea ſervice. Here his merit and talents were ſoon appreciated; and here he married the daughter of Pereſtrelle, one of the captains employed by prince Henry in his early navigations, and who, under his protection, had diſcovered and planted the iſlands of Porto Santo, and Madeira. Columbus got poſſeſſion of the journals and charts of this experienced navigator, and from them he learned the courſe which the Portugueſe had held in making their diſcoveries, as well as the various circumſtances which guided and encouraged them in their attempts. While he contemplated the labours of his father-in-law, and read the deſcription of the countries which he had ſeen, his own impatience to viſit them became irreſiſtible. To indulge it he made a voyage to Madeira, and for ſeveral years traded with that iſland, with the Canaries, the Azores, the ſettlements in Guinea, and all other places which the Portugueſe had diſcovered on the continent of Africa. He now began to think of extending the boundaries of nautical knowledge. He was ſatisfied, not only that there muſt be lands ſtill further to the weſt, than thoſe already explored, but that a ſhorter paſſage to the Eaſt Indies, then the great object of the Portugueſe navigators, might be found by ſteering in that direction, than round the continent of Africa. When he had ſettled his plan, he was anxious to ſecure the patronage and ſupport of ſome European power capable of undertaking ſo important an enterpriſe. With this view, he laid his ſcheme before the ſenate of Genoa, and, making his country, for which he bore a filial and ſincere affection, the firſt tender of his ſervice, offered to ſail under the banners of that republic, in queſt of new regions, which he expected would render illuſtrious his own name, and the nation which ſhould enable him to realize his vaſt projects. Genoa rejected his offer: and Portugal, to whom he next applied, treated him with ſo much duplicity, that he went himſelf to Spain, while at the ſame time he ſent his brother Bartholomew into England to make the like propoſals to both courts. By both, his ſchemes were at firſt ſlighted, till, by the interpoſition of ſome zealous friends at the court of Spain, a change was effected in his favour, and in the ſpring of 1472 a treaty was ſigned with Columbus, by which Ferdinand and Iſabella, the ſovereigns of Spain, appointed him their high admiral in all the ſeas he ſhould diſcover, and their viceroy in all the iſlands and continents. They granted him and his heirs a tenth of all the profits that ſhould accrue from the enterprize, with ſome other important advantages. As ſoon as the treaty was ſigned, Iſabella, by her activity and attention, in forwarding the preparations for the voyage, endeavoured to make ſome reparation to Columbus for the time which he had loſt in fruitleſs ſolicitation.

On the third of Auguſt 1492, Columbus ſet ſail with three ſmall ſhips and ninety men. The expence of which did not amount to more than 4000*l.* He had already, in the moſt public manner, implored the guidance and protection of heaven, and on the morning of his departure the ſhores were crowded with ſpectators, who ſent up their ſupplications to the Almighty for the proſperous iſſue of the voyage. Columbus ſteered directly for the Canaries, where, on account of the ill condition of the ſhips, he was obliged to refit. Having ſupplied himſelf with freſh proviſions, he ſailed from Gomera, one of the moſt weſterly of the Canary iſlands, on the ſixth day of September. Here the voyage of diſcovery may be ſaid to begin; for Columbus holding his courſe due weſt, left immediately the uſual track of navigation, over a vaſt and unknown ocean, with no other guide, than well-founded hopes and rational conjectures. Scarcely had he loſt ſight of the Canaries, when ſeveral of his men exhibited ſigns of conſternation bordering on deſpair. He comforted them with the vaſt wealth which was to be found in thoſe regions whither he was conducting them, and in his own perſon he ſet ſuch an example of patience and induſtry as could not fail of exciting the admiration of thoſe about him. Scarcely did he allow himſelf time for neceſſary refreſhments: he regulated every thing; he ſuperintended the execution of every order, and kept the deck with the ſounding line or inſtrument for obſervation perpetually in his hand, and noting down every unuſual appearance with the utmoſt accuracy and preciſion. Three weeks had they traverſed the ocean, and had proceeded to a diſtance which Columbus thought it prudent to conceal, when his men became mutinous, and even threatened to throw their admiral overboard ſhould he perſiſt in an undertaking which they ſuppoſed muſt prove fatal to them all. He ſucceeded for the preſent in quieting their apprehenſions, but in a few days they became more violent, declaring that nothing ſhould induce them to proceed in ſo mad an enterpriſe; after trying every means of perſuaſion in vain, he at length promiſed to direct his courſe homewards within three days, ſhould not land be diſcovered. This propoſition did not appear unreaſonable to the men, and to the commander it appeared ſufficiently ſafe, for the preſages of diſcovering land by the flight of birds, &c. were now ſo numerous and promiſing that he deemed them infallible. From a variety of ſymptoms Columbus was ſo confident of being near land, that on the evening of the 11th of October, after the uſual invocations to heaven for ſucceſs, he ordered the ſails to be furled, and the ſhips to lie to, keeping the ſtricteſt watch, leſt they ſhould be driven on ſhore. During this interval of ſuſpenſe and expectation, no man ſhut his eyes, all kept upon deck, gazing intently towards that quarter where land was expected to be diſcovered. At ten o'clock Columbus, ſtanding on the forecaſtle, obſerved a light at a diſtance: he pointed it out to another, and he again to a third perſon; all three ſaw it in motion, and at midnight there was heard from the foremoſt veſſel the joyful ſound of *land, land.* Having, however, been frequently deceived by falſe appearances, every man was ſlow of belief; and waited in all the anguiſh of uncertainty and impatience for the return of day. When the morning dawned their doubts were diſpelled, and an iſland was ſeen about two leagues to the north, whoſe verdant fields, well ſtored with wood, and watered with many rivulets preſented the aſpect of a delightful country. Thankſgivings were inſtantly offered to heaven: never was gratitude more ſincere, never were the expreſſions of joy more ardent, than thoſe which proceeded from every tongue. Their duty to God was followed by an act of juſtice to their commander. They threw themſelves at the feet of Columbus, with feelings of ſelf-condemnation, mingled with reverence entreating pardon for their paſt conduct; and now they regarded as the favourite of heaven the man whom they lately reviled as a viſionary and impoſtor. No ſooner had the ſun tinged with its rays the ſhores of the newly diſcovered iſland, than their boats were manned and armed. As they approached the coaſt with colours, muſic, and martial grandeur, they ſaw it covered with a multitude of people, whom the novelty of the ſpectacle had drawn together, whoſe attitudes and geſtures expreſſed wonder and aſtoniſhment at the ſtrange objects which preſented themſelves to their view. The land proved to be one of the Bahama iſlands, named afterwards by Columbus, San Salvador: he was the firſt European who ſet foot in the New World which he had diſcovered, and he took ſolemn poſſeſſion of it for the crown of Caſtile and Leon, with all the formalities which the Portugueſe were accuſtomed to obſerve in acts of this kind, in their new diſcoveries. The Spaniards, while thus employed, were ſurrounded by many innocent and unſuſpecting natives, who gazed in ſilent and awful admiration upon actions which they could not comprehend, and of which they could not foreſee the direful conſequences. Towards the evening Columbus returned to his ſhips accompanied with many of the iſlanders in their canoes. "Thus," ſays Dr. Robertſon, "in the firſt interview between the inhabitants of the Old and New Worlds, every thing was conducted amicably, and to their mutual ſatisfaction. The former, enlightened and ambitious, formed already vaſt ideas with reſpect to the advantages which they might derive from the regions that began to open to their view. The latter ſimple and undiſcerning had no foreſight of the calamities and deſolation which were approaching their country."

From San Salvador, Columbus proceeded on other diſcoveries; he ſaw ſeveral iſlands, and touched at three of the largeſt, on which he beſtowed the names of St. Mary of the Conception, Ferdinanda, and Iſabella. He viſited alſo Cuba and Hiſpaniola; wherever he went he inquired for gold, and having obtained a certain quantity of the precious metal, and made other arrangements, he took his departure homewards. He encountered a violent tempeſt, in which he had nearly loſt his ſhips. While all on board were overwhelmed with a ſenſe of perſonal danger, Columbus was only anxious for the means of preſerving a record of his great diſcoveries. Retiring to his cabin, he wrote an account of what he had ſeen and done, which he covered with wax, encloſed in a tight caſk, and committed to the ſea with a proper direction, hoping that it might be fortunately landed on ſome European ſhore. The ſtorm, however ceaſed, and in a few days he found himſelf approaching the Azores. Here he obtained proviſions, and renewed his voyage. When he was almoſt within ſight of the Spaniſh coaſt, another ſtorm aroſe, that forced him to take ſhelter in the Tagus, from whence he proceeded to Liſbon; where, in the preſence of the king of Portugal, he narrated every thing that he had done and ſeen. Columbus remained at Liſbon but five days, and on the fifteenth of March he arrived in the port of Palos, ſeven months and eleven days from the time when he ſet out thence. As ſoon as his ſhip was diſcovered, the inhabitants ran eagerly to the ſhore, to welcome their relations and fellow-citizens, and to learn the tidings of their voyage. Columbus repaired to the court, then at Barcelona, where he was received with all the reſpect and honour due to his great atchievements. Every mark of attention that gratitude or admiration could ſuggeſt was conferred upon him. All his ſtipulated privileges were confirmed, his family was ennobled; and, which was moſt ſatisfactory to his active mind, another armament was immediately fitted out for him. This conſiſted of 17 ſhips and about 1500 perſons; of whom a large number were men of diſtinction, deſtined to ſettle in the newly diſcovered countries.

On the 25th day of September 1493, Columbus ſailed on his ſecond voyage from Cadiz. He firſt reached the Caribbee or Leeward iſlands, which he viſited, and then proceeded to Hiſpaniola, where he had left a ſmall garriſon of his own men, but who had been deſtroyed, probably from miſconduct on their own parts, by the natives. Inſtead of waſting his time in puniſhing paſt wrongs, Columbus took precautions for preventing any future injury. With this view he built a ſmall town, which he named Iſabella, in honour of his royal patroneſs. While ſome were employed in the neceſſary operations of building, he ſent others to explore the interior of the country, in the hope of finding gold. The hardſhips to which the Spaniards were obliged to ſubmit, rendered them impatient of control, and it was with the utmoſt difficulty that Columbus could maintain any ſubordination. Signs of mutiny were every where exhibited; and to the commander was imputed the moſt unworthy motives, by perſons from whoſe rank in ſociety better and more rational conduct might have been expected. Having, however, by prudence and vigour allayed the ferment, he left his brother Diego as governor of the ſettlement, and proceeded with a ſquadron in queſt of new diſcoveries. During a tedious voyage of five months, in which he endured every hardſhip, he diſcovered only the iſland of Jamaica. But on his return to Hiſpaniola, he had the ſatisfaction of finding there his brother Bartholomew, whom he had not ſeen for a long period, and who had brought with him a large ſupply of proviſions and men. About this period the native Indians perceiving that the yoke impoſed upon them by the invaders would prove intolerable, reſolved, if poſſible, to free themſelves from ſo dreadful an evil. Hoſtilities were commenced, and much blood was ſhed on both ſides; but in the event the Indians were completely defeated. The conſternation with which the Indians were filled by the noiſe and havoc made by the fire-arms, by the impetuous force of the cavalry, and the fierce onſet of twenty large dogs trained for the purpoſe, was ſo great, that they threw down their weapons, and fled, without attempting farther reſiſtance. Many were ſlain, more were taken priſoners, and reduced to a ſtate of the moſt humiliating ſervitude; a rigorous tax was impoſed upon them of gold, which was the deareſt object of European ambition, and which was now become neceſſary to plead the cauſe of Columbus in Spain, where numerous accuſations had been laid againſt his conduct. Willing, however, to meet the charges in perſon, he inveſted his brother Bartholomew with full power of government during his abſence, and then ſet ſail. He arrived in Spain in 1496, and immediately appeared at court, with the modeſt but determined confidence of a man, conſcious not only of his own integrity, but of having performed many very eminent ſervices for the ſtate, in whoſe employment he had embarked. The dignity of his conduct ſilenced his enemies; and, with the aſſiſtance of the gold and precious commodities which he had brought with him, he recovered the good opinion of his ſovereigns. They reſolved to make every exertion to render the new colony a permanent and complete eſtabliſhment, by ſending out ſuch reinforcements as Columbus thought neceſſary for the purpoſe.

It was not, however, till late in the ſpring of 1498, that he was enabled to proceed on his third voyage; during which he diſcovered Trinidad, at the mouth of the Orinoco. The vaſt ſize of this river, though only ranking in the third or fourth magnitude of rivers in the New World, convinced him that it muſt have its riſe in a great continent. He even touched upon various parts of the continent, without ſuſpecting it, conceiving that they belonged to iſlands which he had not leiſure to explore. Columbus arrived at Hiſpaniola in Auguſt, where he found that his brother had removed the colony to St. Domingo, on the oppoſite ſide of the iſland. During his abſence, a mutiny had been excited, and ſome of his people had ſeceded from the main body. To calm the diſcontent, he gave them allotments of land, to which were annexed diſtributions of poor natives, that proved to them an intolerable ſource of oppreſſion. New complaints were ſecretly tranſmitted to court againſt him and his brothers; and having no opportunity of vindicating his conduct, his powers were at firſt greatly abridged by a ſeparate commiſſion of diſcovery having been granted to Alphonſo d'Ojeda; who was accompanied in his voyage by Amerigo Veſpucci, after whom the whole New World has ſince been named. Columbus was then recalled, and Francis de Bovadilla appointed in his ſtead. By his unworthy and inſolent ſucceſſor, Columbus was thrown in chains, and treated with other indignities, which have for ever diſgraced the court that granted to him ſo much power. The captain of the ſhip, to whoſe charge Columbus was given, offered, in the moſt reſpectful manner, to liberate him, but he indignantly refuſed to ſuffer his irons to be removed, but by the expreſs command of his ſovereigns. On his arrival in Spain, he was inſtantly ſet at liberty, and treated with that civility and kindneſs from the king and queen which he had formerly experienced. Bovadilla was diſgraced, but Columbus could not forget the injuries which he had ſuſtained; he carried with him, wherever he went, the fetters he had worn, and ordered that they ſhould be buried in the ſame grave with himſelf.

In 1502, he obtained permiſſion to make a fourth voyage and on arriving off St. Domingo, he found eighteen ſhips richly laden ready to depart for Europe. His own experience led him to perceive an approaching ſtorm; he accordingly requeſted permiſſion to enter the harbour, and at the ſame time warned the fleet of the dangers to which it would infallibly be expoſed by ſailing at that juncture. His requeſt and his warning were equally diſregarded. The hurricane came on, and though, by proper precautions, he ſaved his own veſſels, it fell upon the fleet with ſo much violence, that only two or three veſſels eſcaped; and Bovadilla, with ſeveral others of his moſt inveterate enemies, periſhed with all their ill-gotten wealth. Among the veſſels that weathered the ſtorm, was that on which the wreck of Columbus's property was embarked. This, which, by ſome, was referred to the ſuperintendence of providence, was, by others, imputed to certain magical arts exerciſed by Columbus himſelf. In purſuing his voyage, he traced the coaſt of Darien, in hopes of diſcovering a ſtrait, which he fondly imagined would open a new tract to the Eaſt Indies. Although he was diſappointed in his expectations, he was, nevertheleſs, ſo much delighted with the fertility of the country, and conceived ſuch an idea of its wealth, from the ſpecimens of gold produced by the natives, that he reſolved to leave a ſmall colony upon the river Belem, in the province of Veragua, under the command of his brother, and to return to Spain, to procure the means requiſite for rendering the eſtabliſhment permanent. On his voyage, he was driven back by a violent tempeſt from the coaſt of Cuba, his ſhips fell foul of one another, and were ſo much ſhattered by the ſhock, that with the utmoſt difficulty they reached Jamaica. Here he endured the greateſt calamities, as well from the mutinous diſpoſitions of his own men, as from the ſuſpicions of the natives, who refuſed to ſupply him with proviſions, till, by his ſkill in aſtronomy, he predicted the event of an approaching eclipſe, a circumſtance that gave him an irreſiſtible authority over their minds. From this time the ſuperſtitious natives venerated him as a god, and not only furniſhed him profuſely with proviſions, but cautiouſly avoided every thing that could give him offence. Columbus was at length delivered by a fleet ſent from Hiſpaniola; and, after various difficulties, he arrived at St. Lucar in Spain in December 1504. Here, in addition to his other ſufferings, he learned that his patroneſs, Iſabella, was dead: from her alone he anticipated the redreſs of his wrongs, which he little expected from the king. To him, however, as the laſt reſort, he applied, who amuſed him with promiſes, but, who, inſtead of granting his claims, inſulted him with the propoſal of renouncing them all for a penſion. Diſguſted with the ingratitude of a monarch whom he had ſerved with fidelity and ſucceſs; exhauſted with the calamities which he had endured; and broken with the infirmities which theſe brought upon him, Columbus breathed his laſt at Valladolid, on the 20th of May 1506, in the 59th year of his age. In the cloſing ſcene he exhibited a dignity and compoſure of mind ſuitable to the greatneſs of his character, and to thoſe ſentiments of piety which he had ever cheriſhed in all the trials to which his life had been expoſed. Ferdinand, who had ſlighted his well-founded claims when living, beſtowed upon him funeral honours, and confirmed to his children their hereditary rights. Columbus was buried in the cathedral at Seville, and on his tomb was engraven an epitaph, in memory of his renowned actions and diſcovery of a New World, which in juſtice ought to have been denominated Columbia, in order that the name might for ever excite the remembrance of the hero who, in ſpite of every obſtacle, ſucceeded in realizing a project, eſteemed by his contemporaries as the chimera of a diſturbed imagination. Robertſon's Hiſt. of America.

Juſtinianus, in his curious edition of the Polyglot Pſalter, 1516, of which a beautiful copy is preſerved in the Cracherode collection in the Britiſh Muſeum, has introduced, by way of commentary on Pſ. xix. 4. "their words are gone forth to the ends of the earth," a very curious ſketch of the life of Columbus, an account of his diſcovery of America, and alſo a deſcription of the inhabitants, particularly of the female native Americans.

Columbus, *Congregation of St.*, is the name of a congregation of regular canons, formerly of great extent; having under it an hundred abbeys or monaſteries, in the Britiſh iſlands. See Congregation and Canon.

COLUMELLA, in *Anatomy*. See Uvula.

Columella, in *Botany*, is uſed by Linnæus for the central pillar of a capſule, to which the ſeeds are uſually attached. Gærtner is content with the term receptacle for this part. See Receptacle.

Columella, Lucius, Junius, Moderatus, in *Biography*, was born at Cadiz, and flouriſhed at Rome in the time of the emperor Claudius. He is chiefly celebrated for a work which has come down to our own times, entitled "De Re Ruſtica," and which contains, in twelve books, rules concerning the culture of various vegetables, and the management of domeſtic animals. A ſeparate book "De Arboribus," is annexed to theſe. They have gone through many editions, but the beſt and moſt accurate is that in Geſner's collection of the Rei Ruſticæ Scriptores. Moreri.

Columellæ *muſculus teres*, a name given by Morgagni, and ſome others, to the muſcle called by Albinus *azygos uvulæ*.

COLUMELLIA, in *Botany*, Willd. 1525. Jacq. Hort. Schoenb. 3. 28. tab. 301. Claſs and order, *ſyngeneſia ſuperflua*. Nat. Ord. *Compoſitæ*, Linn. *Corymbiferæ*, Juſſ. Vent.

Eſſ. Ch. Receptacle naked, honey-combed. Down with a toothed margin. Common calyx cylindrical, imbricated. Rays of the florets undivided.

Sp. C. *biennis*. *Root* biennial. *Stem* cylindrical, pubeſcent, corymbous at the top. *Leaves* an inch and a half long, ſeſſile, linear, obtuſe, hairy. *Flowers* both of the diſk and ray yellow, ſeſſile, ſolitary at the diviſions of the branches. A native of the Cape of Good Hope.

COLUMN, in *Architecture*, *columna*, Latin, derived from *columen*, a ſupport. In a ſtrictly architectural ſenſe a column may be defined as an object conſiſting of a nearly cylindrical ſhaft with a capital, and either with or without a baſe. The column, as forming the principal part of an order of architecture, will be conſidered under the articles Doric, Ionic, Corinthian, Tuscan, and Composite *Orders*, and in the preſent article we ſhall treat of columns according to their matter, conſtruction, diſpoſition, and uſe; under the firſt head may be placed

Column, *moulded*, is that made by impaſtation of gravel and flints of divers colours, which are bound together with a cement, which grows perfectly hard, and receives a poliſh like marble

The ſecret of making theſe, it appears, the ancients were maſters of, by the columns lately diſcovered near Algiers; which are, doubtleſs, the ruins of the ancient Julia Cæſarea; on all theſe is found the very ſame inſcription in antique characters; the contours, accents, and even faults, being repeated in every ſhaft; an inconteſtible proof of their being moulded.

Column, *fuſible*. Under this term are comprehended, not only columns of various metals, and other fuſible matters, as glaſs, &c. but alſo thoſe of ſtone, ſaid to have been caſt; the ſecret of which ſome will have us believe to have been known to the ancients.

Column, *tranſparent*, any column made of tranſparent matter; as were thoſe of cryſtal in the theatre of Scaurus, mentioned by Pliny; and thoſe of tranſparent alabaſter, in the church of St. Mark, at Venice.

Column, *water*, is a ſort whoſe ſhaft is formed of a large *jet d'eau*; which ſpouting out water violently from the baſe drives it within the tambour of the capital, which is made hollow; whence, falling down again, it has the effect of a liquid cryſtal column. See Fountain.

An inſtance of this we have at Quinto d'Aveiro, near Liſbon.

Column, *hydraulic*, is that whoſe ſhaft appears to be of cryſtal; being formed by a number of little threads of water, falling from holes made in a girt of metal, at equal diſtances, by means of a pipe mounting through the middle thereof; as in the gardens at Verſailles.

Column, *hydraulic*, alſo denotes a column from whoſe top proceeds a *jet d'eau*, to which the capital ſerves as a baſon; whence the water deſcends by a little pipe, which turns ſpirally around the ſhaft. Such are the Ionic columns of the caſcade of the Belvidera at Freſcati; and thoſe of the vineyard Matthei at Rome.

Columns, *with regard to their Conſtruction*.

Column *of bands or tambours*, a column whoſe ſhaft is formed of ſeveral courſes of ſtone or blocks of marble of leſs height than the diameter of the column, this is what Ulpian means by *columna ſtructilis*, or *adpacta*, which is oppoſite to the *columna ſolida*, or *integra*, i. e. of one piece. This method is only practiſed in very large columns, for inſtance as the Trajan column. Smaller columns are often compoſed of three or four pieces, and this method the French diſtinguiſh by a particular term, *colonne par troncons*, of which we have no proper tranſlation.

Column *of Maſonry*, is built of rough ſtones or compaſs bricks, and covered with ſtucco.

Column, *geminated*, that whoſe ſhaft is formed by three ſimilar and equal ſides, or ribs of ſtone, fitted within one another; and faſtened at bottom with iron pins, and at the top with cramp-irons. This is to be fluted, that the joints may be the leſs diſcernible.

Column, *encruſtated*, is made of ſeveral ribs, or thin ſhells of fine marble, or ſome other rare ſtone, cemented upon a mould of ſtone, brick, or the like. This is done with deſign both to ſave the precious matter, as oriental jaſper, lapis lazuli, agate, &c. or to repreſent pieces of ſuch ſtones of an extraordinary ſize, by the neatneſs and cloſeneſs of the incruſtation, which renders the joints imperceptible.

Column, *banded*; a column whoſe ſhaft has ſeveral bands or cinctures either plain or ornamented, which project ſomewhat beyond the general line of the ſhaft.

Banded columns were firſt introduced by De Lorme at the Chapel de Villers-Coherets, and at the Thuilleries, who imagined this method of concealing the joints of the different blocks of ſtone forming the ſhafts.

COLUMN, *fluted*, called alſo *channelled*, and *ſtriated column;* that whoſe ſhaft is adorned with flutes or channellings; either from top to bottom, or only two thirds of its height.

COLUMN, *cabled or rudented*, is a fluted column, whoſe channels are filled in with aſtragals which generally reach one third of the height of the ſhaft from the baſe.

COLUMN, *cylindrical*, is that which has neither ſwelling nor diminution.

COLUMN, *diminiſhed*, is that which has no ſwelling, but whoſe ſhaft is tapered in a ſtraight line from the baſe to the capital. This is the method obſerved in, we believe, all the Grecian remains of architecture, and in many of the Roman, as in the portico of the Pantheon. The oppoſite practice of giving an entaris or ſwelling in the middle of the ſhaft is obſcurely mentioned by Vitruvius, and has been generally followed by modern architects.

COLUMN, *oval*. There are a few inſtances of oval columns in the remains of antiquity. The Maſſini Palace at Rome, and the frontiſpiece of the church of the P. P. de la Merci at Paris offer ſome modern examples.

COLUMN, *paſtoral*, that whoſe ſhaft is formed in imitation of the trunk of a tree, with bark and knots.

This kind of column, in the Tuſcan proportion, may be uſed in the gates of parks and gardens; and in the decoration of paſtoral ſcenes, &c.

COLUMN, *polygonous;* a column of which the horizontal ſection forms a polygon. There are various examples of this form in Egyptian architecture, it is alſo obſerved in the lower part of the columns of a portico on the iſland of Delos and at the temple of Cora.

COLUMN, *twiſted*, a column whoſe ſhaft is twiſted round in the manner of a ſcrew with ſix circumvolutions. Vignola firſt diſcovered a method of drawing it by rule. The barbarous and ridiculous practice of twiſting columns has been much uſed by modern architects, eſpecially in the ſcreens and altar-pieces of churches. The moſt celebrated inſtance is the Baldaquin of St. Peter's. Columns ſpirally fluted are ſeen in the temple of Spolets, they are alſo not unfrequent on the ſarcophagi's and other ornamental works of the lower ages.

COLUMN, *Corolitic*, that adorned with foliages, or leaves and branches turned ſpirally around the ſhaft; or in form of crowns and feſtoons.

Theſe were uſed by the ancients for erecting ſtatues on; which hence took the denomination of *corolitic*. They are very ſuitable in triumphal arches, and decorations of theatres.

COLUMN, *hermetic*. See HERMA.

COLUMNS, *denominated from their diſpoſition*.

COLUMN, *inſerted*, or *backed*, is that let into a well, a third or fourth part of its diameter.

COLUMN, *niched*, is that whoſe ſhaft enters, with half its diameter, into a wall, which is hollowed for its reception; with its plane parallel to the projecture of the tore. Such is that in the portal of St. Peter at Rome.

COLUMN, *angular*, is an inſulated column, placed in the coin, or corner of a portico; or inſerted into the corner of a building: or even a column that flanks an angle, either acute or obtuſe, of a figure of many ſides.

COLUMNS, *cantoned*, are thoſe engaged in the four corners of a ſquare pillar, to ſupport four ſprings of an arch.

COLUMNS, *coupled*, are thoſe diſpoſed, by two and two, ſo as almoſt to touch each other at their baſes, and capitals, as thoſe in the periſtile of the Louvre and at St. Paul's cathedral.

COLUMN, *doubled*, is an aſſemblage of two columns, joined in ſuch a manner, as that the two ſhafts penetrate each other with a third of their diameter. Such are thoſe of the four angles in the court of the Louvre.

COLUMN, *flanked*, according to M. Blondel, is a column engaged with one half, or at leaſt one-third of its diameter, between two demi-pilaſters.

COLUMNS, *grouped*, are thoſe placed on the ſame pedeſtal, or ſocle; either by three and three, or by four and four.

COLUMN, *inſulated*, is that ſtanding free, and detached on all ſides, from any other body.

COLUMNS, *median*. Vitruvius gives the name *columnæ medianæ* to the two columns in the middle of the porch, which have their intercolumniation larger than the reſt: that if theſe laſt, for inſtance, be *pycnoſtle*, the *medianes* are *euſtyle*.

The term may alſo be applied to the middle row of columns, in a frontiſpiece adorned with three orders.

COLUMNS, *denominated from their uſe*.

COLUMN, *aſtronomical*, is a kind of obſervatory, in form of a very high tower; built hollow, and with a ſpiral aſcent to an armillary ſphere placed at the top, for obſerving the motions of the heavenly bodies.

Such is that, of the Doric order, erected at the Hotel de Soiſſons, at Paris, by Catherine De Medicis, for the obſervations of Orontius Fineus, a celebrated aſtronomer of that time.

COLUMN, *chronological*, that which bears ſome hiſtorical inſcription, digeſted according to the order of time; as by luſtres, olympiads, faſti, epochas, annals, &c. At Athens there were columns of this kind, whereon were inſcribed the whole hiſtory of Greece digeſted into olympiads.

COLUMN, *funeral*, a column placed over a tomb, and bearing an urn, or ſome ſymbol or inſcription relating to the deceaſed. See CIPPUS.

COLUMN, *gnomonic*, is a cylinder, whereon the hour of the day is repreſented by the ſhadow of a ſtyle.

Of theſe there are two kinds: in the one, the ſtyle is fixed, and the hour-lines are no more than the projection of a vertical dial on a cylindrical ſurface.

In the other, the ſtyle is moveable; and the hour-lines are drawn to the different heights of the ſun, in the different ſeaſons of the year. See DIAL.

COLUMN, *indicative*, that which ſerves to ſhew the tides, &c. along the ſea-coaſts. Of this kind, is the nilometer at Grand Cairo, whereon the overflowings of the Nile are expreſſed: by this they form a judgment of the ſucceeding ſeaſon: when the water, for inſtance, aſcends to twenty-three feet, it is a ſign of great fertility in Egypt.

COLUMN, *itinerary*, a column with ſeveral faces, placed in the croſs-ways in large roads; ſerving to ſhew the different routs, by the inſcriptions thereupon.

COLUMN, *lactary*, at Rome, according to Feſtus, was a column erected in the herb-market, which is now the place Montanara; which had a cavity in its pedeſtal, wherein young children, abandoned by their parents out of poverty or inhumanity, were expoſed, to be brought up at the public expence.

COLUMN, *legal*. Among the Lacedæmonians there were columns raiſed in public places, whereon were engraven the fundamental laws of the ſtate.

COLUMN, *limitrophous*, or boundary, is that which ſhews the limits of a kingdom, or country conquered. Such was that, which Pliny ſays Alexander the Great erected at the extremities of the Indies.

As to thoſe of Hercules, ordinarily called his columns, or pillars; they are two very ſteep mountains in the ſtreights of Gades, now Gibraltar.

Column, *manubiary*, from the Latin *manubiæ*, *ſpoils of the enemy;* a column adorned with trophies, built in imitation of trees, whereon the ſpoils of enemies were anciently hung.

Column, *menian*, any column which ſupports a balcony, or meniana. The origin of this kind of column, Suetonius and Aſcanius refer to one Menias; who, having ſold his houſe to Cato and Flaccus, conſuls, to be converted into a public edifice, reſerved to himſelf the right of raiſing a column without-ſide, to bear a balcony; whence he might ſee the ſhows.

Column, *miliary*, was a column of marble, raiſed by order of Auguſtus, in the middle of the Roman Forum; from whence, as a centre, the diſtances of the ſeveral cities, &c. of the empire were reckoned, by other miliary columns diſpoſed at equal diſtances, on all the grand roads. This column was of white marble; the ſame with that which is now ſeen on the balluſtrade of the ſtaircaſe of the capitol at Rome. Its proportion is maſſive; being a ſhort cylinder, ſupporting a ſymbol of the globe of the earth.

It was called *milliarium aureum*, as having been gilt, at leaſt the ball, by order of Auguſtus. It was reſtored by the emperors Veſpaſian and Adrian; as appears by the inſcriptions.

Column, *military*, among the Romans, a column whereon was engraven a liſt of the forces in the Roman army, ranged by legions, in their proper order; with deſign to preſerve the memory of the number of ſoldiers, and of the order preſerved in any military expedition.

The Romans had another kind of military column, which they called *columna bellica*, ſtanding before the temple of Janus; at the foot whereof the conſul declared war, by throwing a javelin towards the enemies countries.

Column, *phoſphorical*, a light houſe; or a hollow column, built on a rock or the tip of a mole, or other eminence, to ſerve as a lantern to a port.

Column, *ſymbolical*, is a column repreſenting ſome particular country, by the attributes proper thereto; as that of the French order, ſet with *fleurs de lis*, in the frontiſpiece of the Jeſuits church at Rouen: or ſome memorable action; as the *Corvinian column*, on which was a crow; erected to Valerius Maximus, ſurnamed Corvinus, in memory of his defeat of a giant in the army of the Gauls, by the aſſiſtance of a crow.

Under the title of *ſymbolic columns*, may alſo be comprehended thoſe that ſerve for ſymbols. Such is that on a medal of Nero, which expreſs the ſtability of the Roman empire. See Symbol.

Columns, *hiſtorical, memorial, honorary, triumphal.* Under this head may be placed various diſtinguiſhed columns, which rank among the eminent works of art ancient and modern, and form the chief ornaments of the ſituation in which they are placed. The moſt celebrated of theſe is the triumphal column of Trajan at Rome. This monument was built by Apollodorus the moſt famous Roman architect in the Forum Romanum. The height of the column is 106 feet, with a diameter of nearly 13 feet; it is placed on a pedeſtal of 19 feet high; upon the capital there is a crowning which formerly ſupported a ſtatue of the emperor, but, at preſent, a bronze ſtatue of St. Peter, about 14 feet in height. The baſe and capital are of the Tuſcan order. The column, with the crowning, is compoſed of 34 tamboons or blocks of white marble, and the ſhaft is adorned, mounting ſpirally from top to bottom, repreſenting the victories of Trajan over the Dacæ. Four eagles at the corners of the pedeſtal ſupport, in their beaks, feſtoons of laurel, and the ſides of the pedeſtal are richly ornamented with a variety of military weapons. The inſide of the column contains a ſtaircaſe, which aſcends to the capital, and as each block of ſtone forms the whole diameter of the ſhaft, the ſteps are wrought out of the ſolid.

The Antonine column, though inferior in deſign, and the beauty of ſculpture to the laſt mentioned, is one of the moſt conſiderable monuments of ancient Rome. It was erected by Marcus Aurelius, and conſecrated by him to Antoninus Pius, whoſe ſtatue was placed upon the ſummit, on the ſhaft however are repreſented the action of Marcus in the Marcoman war. The column is $96\frac{1}{2}$ feet in height, with a diameter of $11\frac{1}{2}$, raiſed upon a pedeſtal of $26\frac{1}{2}$ feet. The conſtruction of this column is exactly ſimilar to that of Trajan; its baſe and capital have Doric profile.

At Alexandria there is a remarkable column, which is commonly called Pompey's pillar. It is a column of the Corinthian order raiſed upon a ſhort pedeſtal. The ſhaft is 67 feet long, and nearly nine feet in diameter, at the bottom of a ſingle piece of granite. The whole height of the column and pedeſtal is about 94 feet.

At Conſtantinople there were two triumphal columns ſimilar to thoſe of Trajan and Antoninus; the column of Conſtantine is entirely deſtroyed, and of the other erected to Arcadius by Theodoſius, only the pedeſtal and the firſt courſe of the ſhaft remains.

Laſtly, may be mentioned the monument of London, which is the largeſt column in exiſtence, being fifteen feet in diameter, and 202 feet high, including the pedeſtal and crowning. This column was erected in memorial of the great fire of London; its architect was Sir C. Wren.

Column, *roſtral*, a triumphal column adorned with the beaks or prows of galies, in memorial of a naval victory. The firſt roſtral column was erected in the capitol, on occaſion of the defeat of the Carthaginians by C. Duillius. Auguſtus conſtructed four with the prows of the ſhips taken from Cleopatra.

Column, *Scenography of.* See Scenography.

Column, in French *Colonne.* Column has been very erroneouſly defined by many writers on military ſubjects to be a long deep file of troops or baggage. This definition, confining a column to a file of troops, ſo far from giving a true idea of it, conveys one totally erroneous. For a column conſiſts both of ranks and files. A column may, therefore, be defined to be a corps or body of men with ranks and files in the form either of a ſquare or rectangle, who march in time, or with one and the ſame movement, leaving a ſufficient interval between every two of the ſaid ranks and files, in order to avoid confuſion. A column may be in the form of a ſquare, having its front equal to its depth; or it may be of a rectangular form, having either its front equal to one of the ſhorteſt ſides of the rectangle, and its depth equal to one of the longeſt, or its front equal to one of the longeſt ſides of the rectangle, and its depth equal to one of the ſhorteſt.

In marching troops in columns, particularly towards the enemy, great care ſhould be taken, that they advance as nearly as poſſible alike, and not one before another, that they may, if attacked, be able to afford mutual aid and aſſiſtance to one another, and that as they approach the field of battle they preſerve their diſtances with ſo much accuracy, that when they wheel and form there may be neither too much nor too little ground for each ſquadron and battalion. This is a nice point, and an operation that is ſeldom executed correctly.

The moſt diſadvantageous order of march is that which compels an army to move in one column. The more columns it is divided into, and the ſmaller their depth, the more eaſily and expeditiouſly are the troops compoſing them formed in order of battle. And the moſt advantageous method of marching an army is that which makes it move in order of battle, without dividing it into columns at all. But open, level, and unembarraſſed ground of ſufficient extent for this purpoſe is rarely to be met with.

Column. *Cloſe*, a ſolid compact column, with very little ſpace or intervals between the diviſions compoſing it.

Column, *Open*, a column with intervals between the the diviſions equal commonly to their reſpective fronts.

Column, among *Printers*, is half a page, when the page is divided into two parts, from top to bottom. See Printing.

COLUMNA, Fabius, in *Biography*, a learned botaniſt, was born at Naples in 1567. He attached himſelf early to the ſtudy of natural hiſtory, particularly to acquire a knowledge of the properties of plants, in which he became eminent. He excelled alſo in the knowledge of languages, of muſic, of mathematics, and in drawing, of which he is ſaid to have made much uſe, the greater part of the engravings in his works being taken from his own deſigns. He was led to ſtudy the works of Dioſcorides, Boerhaave ſays, in order to find a remedy for eliptic fits, to which he was ſubject. That he was not ſucceſsful in his ſearch is probable, as he is ſaid to have received the greateſt benefit, having previouſly tried numerous medicines, by the application of a cauſtic to one of his thighs. The operation was performed by Severinus in the year 1630. He died in 1651, aged 83 years, and is ſaid to have totally out-lived his faculties. Haller gives him great credit as a reviver and improver of the ſtudy of botany, for the light he threw on many obſcure paſſages in Dioſcorides, and for the number of plants he deſcribed not before known. The figures of the plants he has given, which he generally aſſiſted in executing, are among the earlieſt copper-plate engravings in that part of natural hiſtory. His firſt work, which was publiſhed when he was only 24 years of age, "Plantarum aliquot hiſtoria, in qua deſcribuntur plantæ rariores, antiquorum delineationibus reſpondentes." Neap. anno 1592, 4to. far exceeding what had been before done in that line. The engravings alſo are more accurate than had been before ſeen. "In phu (the wild valerian) characterem exacte expreſſit." Haller ſays, it is the plant, the root of which, Dioſcorides recommended in his complaint. He took of it for a long time with advantage, he ſays, but it did not effect a cure. The works were republiſhed in 1744, 4to. by James Plaucus, with obſervations by the Lyncei, a ſociety of naturaliſts, to which Fabius had belonged. Annexed is a ſhort hiſtory of his life. "Minus cognitarum rariorumque noſtro cælo orientium ſtirpium, ecphraſis qua non paucæ ab antiquioribus deſcriptæ diſquiruntur, et declarantur," Rome, 4to. This was prepared for the preſs in the year 1606. The dedication was written in the year 1610, but it did not appear until the year 1616. He now delineated the flowers, fruits, and ſeeds of the plants, and began to arrange them from the ſimilitudes of thoſe parts. A ſecond part of this work ſoon followed. In 1627, his "Adnotationes, et additiones ad opus Franciſci Hernandes, et Nardi Antonii Recchi" appeared. In this he makes further advances in the claſſification of plants, from the reſemblance of the petals. "Stylum et ſtamina novit." In his work appear the firſt dawning of the ſyſtem, by which Linnæus, more than a century afterwards, became immortalized. He was a member of the illuſtrious academy of the Lincei, eſtabliſhed at Rome, which rendered great ſervices to the republic of letters as long as it ſubſiſted. Columna invented a muſical inſtrument, which he called "Sambuca Lyncia," from the name of his academy; it was compoſed of 500 ſtrings of different lengths, and the tone of each was divided in four parts, according to the method of Ariſtoxinus, to include all the genera, diatonic, chromatic, and enharmonic. He publiſhed his invention in a work likewiſe entitled "Sambuca Lyncia," printed at Naples in 1618. Some later editions were publiſhed under the title, "Dell' inſtrumento perfetto." We make no reflections on the excellence of this inſtrument, having never ſeen it; but conjecture, that from the belly being loaded with ſo great number of ſtrings, the tone muſt be very feeble; it muſt likewiſe have been difficult to tune for all the three genera, and ſtill more difficult to keep in tune. Haller Bib. Botan. Eloy. Dict. Hiſt.

Columna *naſi*, is uſed by ſome writers of anatomy, for the fleſhy end of the noſe, jutting out over the upper lip.

Columna *oris*, is ſometimes uſed for the uvula.

Columna *regia*, in *Ancient Geography*, a place of Italy, over-againſt Sicily, on the bank of the ſtrait, and near Regium Julium. It is mentioned in the Itinerary of Antonine.

COLUMNÆ, a name given by Ephorus, cited by Pliny, to a ſmall iſland on the route from the Red Sea to the iſland of Cerne. G. Hardouin thought they were the Maſcarenhas iſles.

Columnæ *albæ*, or white columns, called by Herodotus (l. v. c. 118.) λευκαι ϛηλαι, a place of Aſia Minor, to the ſouth of the river Marſias, and very near it.

Columnæ *carneæ*, in *Anatomy*, called alſo *lacertuli*, and *columnæ cordis*, are ſeveral ſmall muſcles in the ventricles of the heart; derived, and, as it were, detached from the parieties of thoſe ventricles, and connected by tendinous extremities to the valves of the heart.

Theſe little columns, or pillars, being faſtened to the parietes of the heart on one ſide, and the tricuſpid and mitral valves on the other, do, by the contraction in the ſyſtole of the heart, draw out the valves; and by that means not only ſhut the orifices of the veins, but more exactly cloſe the ventricles in their ſyſtole.

Columnæ *herculis*, the columns of Hercules, in *Ancient Geography*, the name given to the ſtrait of Gibraltar, called alſo *Fretum Gaditanum* and *Fretum Herculæum*. Theſe columns of Hercules were properly the two mountains of Calpe in Europe, and of Abyla in Africa. Some have ſuppoſed that Hercules called them by his name; but others conſider Hercules as an imaginary hero, whoſe name is formed of the Phœnician "Harokel," ſignifying a merchant or voyager. Hence, they ſay, it is not aſtoniſhing, that this ſtrait ſhould be called "the Strait of Voyagers," and that its name ſhould be derived from the Phœnician language, ſince the Phœnician navigators had made it known, and continually ſailed through it.

COLUMNAR *Marble*. See Basaltes.

Columnar *ſtrata*, a mineralogical term for the priſms into which different ſtrata of the earth are ſometimes found ſplit or divided, generally in a direction perpendicular to the lamina of the ſtrata or nearly; theſe moſt commonly occur in baſalt or trap, thoſe of Stople in Saxony, exceed 300 feet in length, without any articulation or diviſion. Dolomien obſerved columnar baſalt in the ſtrata of mount

Etna. At Caſtleton in Derbyſhire, Mr. Mawe obſerved an irregular column in the Toad ſtone or trap (Mawe's Derb. p. 40 and 51). Porphyry is often found in a columnar form, ſee 2 Berg. Journ. 1790, 325, and Haiding, 48. Sand-ſtone in the eaſt and north parts of Bohemia, are often ſplit into columns, reſembling baſalts, 2 Berg. Journ. 1792, 70. Lime-ſtone is ſometimes found rent into polygonal pillars of 4, 5, &c. ſides like baſalts, as at Ruoms and Ridon in the Vivarois, and in Saxony. Charpentier 49. See Basalt, Trap and Prismatic *columnars*.

COLUMNARIS, in *Botany*, a name given by ſome to the tail, milky bell-flower; the *campanula lacteſcens*, Ger. Emac. Ind. 2.

COLUMNARIUM, in *Roman Antiquity*, a heavy tribute, demanded for every pillar of a houſe. It was firſt laid on by Julius Cæſar, in order to put a ſtop to the extravagant expences laid out on ſumptuous buildings.

COLUMNEA, in *Botany*, (ſo named by Plumier in honour of Fabius Columna, or Fabio Colonna, of the noble family of Colonna in Italy,) Linn. Gen. 792. Schreb. 1064. Willd. 1210. Plum. 33. Juſſ. 121. Claſs and order, *didynamia angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Scrophulanæ*, Juſſ.

Gen. Ch. *Cal.* One-leafed, deeply five-cleft, generally ſomewhat ſwelling at the baſe, permanent; ſegments erect, equal, lanceolate. *Cor.* monopetalous, much longer than the calyx, labiate; upper lip erect; lower lip two or three-cleft. *Stam.* Filaments four free; anthers joined together. *Piſt.* Germ ſuperior, egg-ſhaped; ſtyle filiform, the length of the upper lip; ſtyle bifid, obtuſe. *Peric.* Capſule globular, one or two-celled. *Seeds* numerous, ſmall, attached to a large receptacle.

Eſſen. Ch. Calyx five-cleft. Corolla labiate; upper lip erect, emarginate; lower lip three-cleft. Anthers connected. Capſule, one or two-celled. *Seeds* bedded in the receptacle.

Sp. 1. C. *Scandens.* Linn. Sp. Pl. Mart. 1. Lam. 1. Willd. 1. Jacq. Hort. vol. iii. tab. 48. Amer. Pict. 38. tab. 170. Plum. Gen. 28. ic. tab. 89. fig. 1. Lam. Ill. tab. 524. fig. 1. "Leaves egg-ſhaped, acute, entire or ſlightly crenated, ſomewhat villous; calyx pubeſcent; ſegments entire; corolla pubeſcent; upper lip undivided." *Root* perennial. *Stem* ſlender, very long, pale green, ſlightly villous, either creeping on the ground, or attaching itſelf to the trunks of trees, by ſmall lateral roots. *Leaves* oppoſite, petioled, reſembling thoſe of Parietaria. *Flowers* blood-red, two inches long, axillary, ſolitary, villous on the outſide, on ſhort peduncles, a little curved. *Capſule* globular, white, ſoftiſh, reſembling a berry, but opening, about the ſize of a nut, one-celled. A native of South America, and the Weſt Indies. There is a ſeminal variety with yellowiſh flowers. 2. C. *longifolia.* Linn. Mant. 90. Mart. 2. Lam. 3. (Achimenes ſeſamoides; Vahl. Symb. 2. 71. Willd. 1190. Babel. Tſiuli. Rheed. Mal. 9. tab. 87. Seſamum javanicum; Burm. Ind. 133.) "Leaves lanceolate, very long, ſomewhat ſerrated, ſmooth." *Stem* about two feet high, herbaceous, quadrangular, ſmooth, branched. *Leaves* three inches long, oppoſite, nearly ſeſſile. *Flowers* red, oppoſite; in ſimple, long, erect, terminal racemes; border of the corolla four-cleft; upper lip large, oblong, entire; lower lip trifid; anthers divided at the baſe into two diverging lobes, connected, and forming a croſs. *Capſule* egg-ſhaped, two-celled, two valved. *Seeds* numerous, fixed in a globular receptacle. A native of the Eaſt Indies. 3. C. *hirſuta.* Mart. 3. Willd. 2. Hort. Kew. 2. 366. Lam. Ill. tab. 524. fig. 2. Swartz. Prod. 94. Flor. Ind. occ. 2. 1080. (Achimenes major; Brown. Jam. 270. tab. 30. fig. 3. Rapunculus [illegible]; Sloan. Jam. 58. Hiſt. 1. tab 100. fig. 1.) "Leaves egg-ſhaped; acuminate, ſerrated, rough, with hairs on the upper ſurface, ſegments of the calyx tooth-ſerrated, hirſute; corolla hirſute; upper lip bifid." *Root* perennial. Whole plant ſucculent. *Stem* thick, throwing its branches to the height of four or five feet when ſupported. *Leaves* oppoſite alternately larger. *Flowers* large, beautifully variegated; ſegments of the calyx almoſt pinnated like thoſe of the roſe. A native of the cooler mountains of Jamaica; introduced in 1780. by the marquis of Rockingham; flowering in November. 4. C. *hiſpida.* Mart. 4. Willd. 4. Swartz. Prod. 94. Flor. Ind. occ. 2. 1083. "Leaves egg-ſhaped, obtuſe, ſlightly toothed, hiſpid hirſute; ſegments of the calyx entire, hairy; ſtem hairy, ſcabrous." A native of Jamaica. 5. C. *natilans.* Mart. 5. Willd. 3. Swartz. Prod. 94. Flor. Ind. occ. 2. 1083. "Leaves ovate-lanceolate, ſlightly toothed, rather ſcabrous, hirſute and coloured underneath; calyx villous; ſegments laciniated; corollas villous." A native of Jamaica, in ſhady woods, attached to the trunks of trees. 6. C. *ſtellata.* Willd. 6. Lour. Cochin. 384. "Leaves ſtillate; flowers ſolitary; ſtem creeping." *Stem* herbaceous, perennial, cylindrical, ſlender, whitiſh. *Branches* ſomewhat erect, four inches long, very tender. *Leaves* egg ſhaped, three lines long, ſerrated, ſtellate in threes, pale green, odoriferous, petioled. *Flowers* white, ſtriped with red, axillary, hirſute, peduncled; tube of the corolla ſcarcely gibbous; upper lip arched, trifid; lower bifid; anthers egg-ſhaped, connected, ſeparated with difficulty. *Capſule* awl-ſhaped, two-celled. The whole plant, except the capſule, hairy. A native of Cochin-china. It is an aquatic, of a very pleaſant appearance and ſmell, and being emollient and cooling, is uſed as a waſh by the women, for which purpoſe it is cultivated in pots or tubs filled with water, having earth at the bottom.

Columnea *erecta*; Lam. See Cyrilla *pulchella.*

Propagation and Culture. All the ſpecies require the heat of a ſtove. They are propagated by ſeeds, and ſhould be treated like other tender exotics.

COLUMNELLA, *little column*, denotes the ſubſtance that paſſes through the capſule, and connects the ſeveral partitions and ſeeds.

COLUMNIA Pompei, in *Ancient Geography*, a place of Thrace, at the entrance of the Thracian Boſphorus, on the coaſt of the Euxine ſea.

COLUMNIATED *winding ſtairs.* See Stairs.

COLUMNIFERÆ, in *Botany*, the thirty fourth natural order in the "Philoſophia Botanica," of Linnæus, and the thirty-ſeventh of "Prælections." In the "Philoſophia Botanica," it contains the following genera; camellia, xylon, goſſypium, urena, hibiſcus, turnera, malope, lavatera, althæa, alcea, malva, melochia, ſida, napæ, waltheria, mentzelia, hermennia, helicteres, and ſtewartia. In the Prælections all theſe are continued, except mentzelia, which is removed to the calycanthemæ; and xylon, which was ſuppreſſed as a diſtinct genus by Linnæus himſelf, and its ſpecies placed under bombax. The following are added by Linnæus, triumfetta, bixa, corchorus, theobroma, grewia, muntingia, tilia, all of which originally formed part of the now ſuppreſſed order culmineæ; and beſide theſe, malachra? pentapetes, bombax, adanſonia, heliocarpus, antichorus, mahernia, kleinhovia, ayenia, microcos, thea, kiggelaria. Sterculia is placed by Linnæus under both the columniferæ and the tricoccæ. In the "Philoſophia Botanica" it had been placed among the latter, and when it was afterwards removed to the former, it was moſt probably left in its original ſtation, merely through inadvertence. The following have ſince been added; but Giſeke acknowledges himſelf in doubt whether the arrangement would in all caſes have been approved by Linnæus. Symplocos, Linn., and ternſtroemia, Linn., referred to this order by Swartz.; palavia, Cav.: anoda, Cav.; ruizia, Cav; aſſonia, Cav.; dombeya, Cav.; ochroma, Swart.; paronia, Cav; achania, Sol. Swart.; (malvaviſcus, Dill. Cav.) Lagunæa, Cav.; cienfugoſia, Cav.; myrodia, Swart. (Quararibea, Aubl. Cav.), aubletia, Schreb. (Apeiba, marcgr. Aubl. Swart.) Marila, Swart.; bubroma, Schreb.; malacodendron, Mitch. Cav. eroteum, Swart.

Linnæus confeſſes that the eſſential character of the order is not to be underſtood from the name, which properly belongs only to ſome of the more remarkable genera. In all of them the root is fibrous; in none bulbous or tuberous. The ſtem in moſt is herbaceous, but ſome are large trees; it is amongſt the latter only, that thorns are to be found, and prickles only in ſome hibiſci. Scarcely any plant in the whole order is ſmooth. All have ſtipules in pairs. The leaves are never oppoſite, moſt commonly petioled; the foliation, as far as Linnæus could recollect, always plaited, and many have glanduliferous pores under the rib. There are no tendrils in any plant of the order. The infloreſcence is various. The calyx in many is ſimple and five-cleft; in ſome double. The petals in moſt are five; but ſince the filaments are united, and in moſt genera adhere to them, the corolla falls off all together, as if it conſiſted only of one petal. Their claws, by converging often, conſtitute the nectary. The piſtils, or at leaſt the ſtigmas, are equal in number to the parts of the fruit. The fruit is always ſuperior, but various in other reſpects. None of the ſpecies are poiſonous or fetid; they are generally more or leſs mucilaginous; and the flowers of moſt are beautiful.

COLUMPNATENSIS, in *Ancient Geography*, an epiſcopal ſee in Africa in Mauritania Cæſarienſis, according to the conference of Carthage.

COLUPPA, in *Botany*, Rheed. See ILLECEBRUM *ſeſſile*.

COLURES, in *Geography* and *Aſtronomy*, are two great circles, imagined to interſect each other at right angles in the poles of the world.

The word is derived from κολος, *mutilus*, or *truncatus*, and ȣρα, *tail*; q. d. *appearing with the tail cut off*; becauſe never ſeen entire above the horizon.

The colures paſs one of them through the ſolſtitial, and the other through the equinoctial point of the ecliptic; whence the firſt is denominated the *ſolſtitial*, and the ſecond *equinoctial colure*.

The equinoctial colure determines the equinoxes; and the ſolſtitial, the ſolſtices.

By thus dividing the ecliptic into four equal parts, they alſo mark the four ſeaſons of the year.

It is diſputed over what part of the back of Aries the equinoctial colure paſſed in the time of Hipparchus. Sir Iſaac Newton, in his Chronology, takes it to have been over the middle of the conſtellation. Father Souciet inſiſts on its having paſſed over the dodecatemorion of Aries, or midway between the rump and firſt of the tail. We have ſome obſervations in the Philoſophical Tranſactions, N° 466, concerning the poſition of this colure in the ancient ſphere, from a draught of the conſtellation Aries, in the Aratæa publiſhed at Leyden and Amſterdam, 1652, which ſeem to confirm ſir Iſaac's opinion; but the antiquity and authority of the original draught may ſtill remain in queſtion. See CHRONOLOGY.

COLURI, in *Geography*, an iſland in the gulf of Engia, near the coaſt of Livadia, about ſeven miles long and two wide; 10 miles W. of Athens. N. lat. 38°. E. long. 23° 36′.

COLUSITANUS, in *Ancient Geography*, an epiſcopal ſee in the proconſular Africa, according to the conference of Carthage; ſuppoſed to be the ſame with *Calcitanenſes*.

COLUSSA, a Greek town of Paphlagonia.

COLUTEA, in *Botany*, (Κολουτεα, the name of a plant in Theophraſtus). Tourn. Claſs 22. ſect. 3. Gen. 2. Linn. Gen. 880. Schreb. 1196. Willd. 1365. Gært. 488. Juſſ. 359. Vent. 3. 412. Baguenandier; Encyc. Claſs and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ. Vent.

Gen. Ch. *Cal.* Perianth one-leafed, bell-ſhaped, five-cleft, erect, permanent. *Cor.* Papilionaceous. Standard, wings and keel differing in different ſpecies with reſpect to number and proportion. *Stam.* Filaments nine united; one ſeparate; anthers ſimple. *Piſt.* Germ ſuperior, oblong, compreſſed peduncled; ſtyle aſcending; ſtigma bearded on the lower ſide. *Peric.* Legume very large, membranous, tranſparent, generally inflated, appearing almoſt empty, perfectly one-celled. *Seeds* ſmall, kidney-ſhaped, attached to the two edges of the upper ſuture.

Eſſ. Ch. Calyx five-cleft. Stigma bearded on one ſide. Legume peduncled, membranous, inflated or compreſſed, one-celled.

Obſ. This ſpecies is nearly allied to aſtragalus and phaca. The total want of a partition in the legume is its only certain generic diſtinction. The aſtragali are completely two-celled. The phacæ have a partial partition, which extends the whole length, but only half the breadth of the legume, making it ſemi-bilocular.

Sp. 1. C. *arboreſcens*. Common bladder-ſenna. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gært. tab. 154. fig. 4. Lam. Ill. 624. fig. 2. Bot. mag. tab. 81. (C. veſicaria; Bauh. Pin. 396. Tourn. 649. C. hirſuta; Roth. Germ. I. 305. II. 168.) "Leaflets inverſely heart-ſhaped." Linn. "Leaflets oval-obcordate; ſtandard gibbous, abbreviated." Hort. Kew. A ſhrub. *Stems* ſeveral, woody, twelve or fourteen feet high; branches numerous, woody. *Leaves* alternate, winged, terminated by an odd one; leaflets nine or eleven, green and ſmooth above, glaucous underneath. *Flowers* yellow, with a reddiſh curved line at the baſe of the ſtandard, in a ſhort raceme, conſiſting of three or four flowers; wings only a little ſhorter than the keel. *Legume* cloſed at the tip. *Seeds* twenty or more. A native of the warmer parts of Europe; obſerved by Mr. Ray, in the aſcent to the crater of mount Veſuvius, where there are ſcarcely any other plants. It flowers with us in the early part of June, and ſometimes again in the month of Auguſt, continuing till October. Both leaves and legumes are purgative, and may be ſubſtituted for the officinal ſenna, (caſſia ſenna,) but muſt be taken in larger doſes. They have an acrid, nauſeous taſte. The ſeeds, in the quantity of a dram or two excite vomiting: but notwithſtanding theſe qualities, the plant is ſaid by Haller and Ray to afford a food grateful to cattle. 2. C. *cruenta*. Oriental bladder ſenna. Mart. 2. Willd. 2. L'Heretier Stirp. nov. 2. tab. 41. Hort Kew. 3. 55. Lam. Ill. tab. 624. fig. 3. (C. orientalis, flore, ſanguinei coloris, luteâ maculâ notato. Tourn. Cor. 44. C. ſanguinea. Pal. roſſ. 1. 88. C. orientalis. Lam. 2. C. humilis. Scop. inſubr. 2. 23: tab. 12) "Shrubby; leaflets wedgſhaped, inverſely heart-ſhaped; ſtandard gibbous, obtuſe, very ſmall." *Stem* woody; branches ſeven or eight feet high. *Leaves* pinnated; leaflets eleven or thirteen, ſmall, ſmooth, glaucous, more fleſhy than thoſe of the preceding ſpecies.

Flowers deep red, with two yellow ſpots on the ſtandard, ſmall; wings conſiderably ſhorter than the keel; keel erect, appearing cut off at the end. *Legume* opening beneath the tip into a wide hole. Diſcovered by Tournefort in the Levant; cultivated by Miller in 1752. 3. C. *pocockii.* Pocock's bladder-ſenna. Mart. 3. Willd. 3. Hort. Kew. 3. 55. (C. procumbens; L'Heretier Stirp. nov. 2. tab. 42. C. halepica; Lam. 3.) "Shrubby; leaflets roundiſh-elliptical, very obtuſe, mucronate; ſtandard gibbous, elongated, aſcending." A lower ſhrub than the preceding. *Branches* ſlender, ſpreading. *Leaflets* thirteen or fifteen, very ſmall, entire, of a cinereous-green colour underneath. *Flowers* bright yellow, larger than thoſe of C. arboreſcens, opening a month earlier, and continuing in ſucceſſion till late in the autumn; peduncles ſhorter than the leaves, axillary, ſolitary, one or two-flowered. The ſeeds were firſt brought to England from Turkey, by Dr. Pococke, and are ſaid by Dr. Ruſſell to be very common about Aleppo. 4. C. *fruteſcens.* Scarlet bladder-ſenna. Linn. Sp. Pl. 2. Mart. 4. Lam. 4. Willd. 4. Bot. Mag. tab. 181. "Leaflets oblong, retuſe, hoary underneath; branches ſilky-tomentous." A ſhrub, from two to four feet high; branches erect. *Leaflets* from twenty-one to twenty-five, green and ſmooth on their upper ſurface. *Flowers* bright ſcarlet large; peduncles axillary, from three to five-flowered; keel conſiderably longer than the ſtandard; wings very ſmall. *Legumes* very large. A native of the Cape of Good Hope, and other parts of Africa. 5. C. *americana.* Mart. 8. Houſt. MSS. "Shrubby; leaflets egg-ſhaped, emarginate; legumes oblong, compreſſed, acuminate." *Stem* twelve or fourteen feet high, much branched; leaflets ſeven, light green. *Flowers* bright yellow, two or three upon each peduncle. *Legumes* near four inches long, compreſſed, winged, ending in long points. Sent to Miller in 1730, by Dr. Houſton, from Vera Cruz in New Spain. 6. C. *galegifolia.* Bot. Mag. tab. 792. "Shrubby; leaflets oval, emarginate, in about nine pairs, with a terminal one; legumes on longiſh pedicels." *Stem* low, zig-zag; branches herbaceous, angular. *Stipules* two, egg-ſhaped, ſmall, embracing the common petiole, but diſtinct from it. *Flowers* dull red, inclining to orange, in a many-flowered raceme; common peduncles longer than the leaves, axillary; pedicels alternate, ſhort, curved; bracte under each flower, ſingle, ſmall, egg-ſhaped; calyx-teeth wide at the baſe, with white villous margins; ſtandard roundiſh, ſomewhat reflexed, marked at the baſe with a greeniſh yellow ſpot; wings ſmaller than the keel; keel one-petalled, when folded nearly orbicular; ſtyle hairy on the upper ſurface of its whole length. *Legume* inflated, membranous, veined, oblong, oval, beaked, on a pedicel four times longer than the calyx. *Seeds* many, ſhining, kidney-ſhaped. A native of New South Wales. 7. C. *procumbens.* Mart. 9. "Stems trailing; leaflets oblong, egg-ſhaped, tomentous; flowers axillary, on very long peduncles." *Stems* ſeveral, woody, ſlender, much branched; branches not much more than a foot long; leaflets twenty-five or twenty-ſeven, ſmall, narrow. *Flowers* purple, ſmall; peduncles with three or four flowers. *Legumes* little more than half an inch long, but like a ſickle, compreſſed. *Seeds* kidney-ſhaped. A native of the Cape of Good Hope. Cultivated by Miller in 1753. 8. C. *rigida.* Willd. 5. Thunb. prod. 134. "Shrubby; leaflets lanceolate, ſmooth; ſtem erect, ſmooth. A native of the Cape of Good Hope. 9. C. *obtuſata.* Willd. 6. Thunb. prod. 134. "Shrubby; leaflets linear; ſtem erect; flowers in racemes, reflexed." A native of the Cape of Good Hope. 10. C. *linearis.* Willd. 7. Thunb. prod. 135. "Herbaceous; leaflets linear, acute; ſtem erect; racemes terminal, incurved." A native of the Cape of Good Hope. 11. C. *herbacea.* Linn. Sp. Pl. 3. Mart. 6. Lam. 5. Willd. 8. Gært. tab. 154. fig. 2. "Leaflets linear, emarginate, ſmooth; ſtem herbaceous; racemes axillary." *Roots* annual or triennial. *Stem* near a foot and half high, clothed with very ſhort hairs, branched. *Leaflets* fifteen or ſeventeen, greeniſh. *Flowers* dark blood-red, ſmall; ſtandard ſtriated, the length of the wings and keel. *Legumes* ſmall, membranous, ſomewhat tranſparent, very thin, compreſſed, egg-ſhaped, obliquely mucronate, two valved, peduncled. *Seeds* two or four, rather large, kidney-ſhaped, compreſſed, of a dull cheſnut colour. A native of the Cape of Good Hope; cultivated by Miller in 1731. 12. C. *perennans.* Mart. 5. Willd 9. Hort. Kew. 3. 56 Jacq. Hort. 3. tab. 3. (C. fiſtuloſa; Retz. Obſ. 3. 40. Mart. 7.) "Herbaceous; leaflets oblong, pubeſcent; ſtem erect; racemes terminal." *Root* perennial. Whole plant ſlightly pubeſcent. *Stem* cylindrical, ſtriated, pale green, annual, ſimple, or with almoſt barren branchlets. *Leaves* alternate, near together, ſpreading; leaflets from thirteen to ſeventeen, entire, obtuſe, on very ſhort petioles. *Flowers* fleſh-coloured, ſmall, without ſcent; ſtandard wide, roundiſh, emarginate, marked with deep purple ſtreaks; wings ſhorter than the keel, oblong, obtuſe; keel dark purple, aſcending at the end, almoſt as long as the ſtandard; ſtyle ſmooth; ſtigma obtuſe, with white villous hairs, but bearded only at the tip. *Legume* ovate-roundiſh, acuminate at both ends, compreſſed, flat, little inflated, ſmooth, membranous, ſomewhat pellucid, not opening of itſelf. *Seeds* few, compreſſed black. A native of the Cape of Good Hope; introduced by Dr. Jacquin in 1776. 13. C. *proſtrata.* Willd. 10. Thunb. prod. 134. "Leaflets lanceolate, villous; ſtem herbaceous, diffuſe; peduncles axillary, with about two flowers." A native of the Cape of Good Hope. We ſhould have ſuppoſed this to be C. procumbens taken up by profeſſor Martyn from Miller, if Miller had not expreſsly aſſerted that his plant has woody ſtems. 14. C. *exciſa.* Willd. 11. Thunb. prod. 134. "Leaflets egg-ſhaped, cut; ſtem herbaceous, decumbent; racemes terminal." A native of the Cape of Good Hope. 15. C. *veſicaria.* Willd. 12. Thunb. prod. 134. "Leaflets egg-ſhaped; ſtem herbaceous, decumbent villous; legumes orbicular, inflated." A native of the Cape of Good Hope. 16. C. *tomentoſa.* Willd. 13. Thunb. prod. 135. "Leaflets egg-ſhaped, hoary; ſtem herbaceous, tomentous; flowers in racemes. A native of the Cape of Good Hope. 17. C. *alpina.* Lam. 6. (Phaca alpina; Linn. P. leguminibus pendulis ſemiovatis; Gmel. Sib. 4. 35. tab. 14. Aſtragulus; Hall. Helv. n. 401. Aſtragaloides elatior, erecta, viciæ foliis, ſiliquis pendulis. Amon. Ruth. 148.) "Herbaceous, much branched; leaflets oblong, elliptical, hairy underneath; flowers pale yellow." *Root* perennial. *Stems* near a foot and half long, weak, ſometimes quite upright, ſometimes half decumbent and diffuſe. *Leaflets* nineteen or twenty-one, green and ſmooth above, diminiſhing in ſize towards the top. *Flowers* yellowiſh, in peduncled ſpikes, ſituated in the axils of the upper leaves; calyx beſet with a few ſhort blackiſh hairs. *Legumes* veſicular, perfectly one-celled, pedicelled in their calyx, demi-oval, or a little creſcent-ſhaped, acute, pendulous on the common peduncle. *Seeds* from four to ſix, ſmall, kidney-ſhaped. A native of the mountains of Dauphiné, Switzerland, Lapland, and Siberia. 18. C. *auſtralis.* Lam. 7. (Phaca auſtralis, Linn.; aſtragalus. Hall. Helv. p. 403. Aſtragaloides alpina ſupina glabra, Till. Hort. Pin. 19. tab. 14. fig. 1.) "Herbaceous, diffuſe; leaflets lanceolate, nearly ſmooth; peduncles longer than the leaf." *Root* perennial. *Stems* from five to ſeven inches long, ſlender, weak, commonly procumbent, almoſt ſmooth, branched. *Leaflets* thirteen or fifteen, acute. *Stipules* two, embracing the ſtem, oval-obtuſe. *Flowers* yellowiſh white, with a tint of violet at the extremity of the keel, ſeſſile, in axillary ſpikes. *Legumes* veſicular, demi-oval, pedicelled in their calyx, terminated by a ſhort bent thread, perfectly one-celled, ſmooth, not pendulous. *Seeds* five or ſix, ſmall. A native of the mountains of Provence, Italy, and Switzerland. After ſome heſitation, we have placed the laſt two ſpecies under this genus, in concurrence with La Marck, although that botaniſt has not, in this particular, been hitherto followed by any other author. Gærtner has even figured the legume of this ſpecies alone, to illuſtrate the genus phaca. As far, however, as the partition is concerned, he compleatly gives up the point, acknowledging the legume to be abſolutely one-celled, without a veſtige of a partition. He has accordingly introduced *aut rarius unicolare*, into his generic character, and has founded the eſſential diſtinction between colutea and phaca on the form of the flowers. To us the entire want of a partition appears deciſive. Jacquin, indeed, has attributed to his alpina a half two-celled legume; but he ſeems to refer to a different plant. There is much confuſion in authors with reſpect to the ſynonyms of phaca-alpina; and that with the kindred ſpecies, ſtands in need of further inveſtigation.

COLUTHUS, in *Biography*, a Greek poet, a native of Lycopolis, lived under the emperor Anaſtaſius in the beginning of the ſixth century. His only work that has come down to us is upon the "Rape of Helen," which, though of inferior merit, has been frequently edited, and was tranſlated into French by M. du Molard in 1742. Moreri.

COLVIUS, Andrew, was born at Dort in Holland, in the year 1594, where he officiated during a conſiderable part of his life as paſtor of the Walloon church. In 1620, he was chaplain to the embaſſy at Venice, and cultivated an intimate friendſhip with the celebrated father Paul, whoſe treatiſe on the inquiſition he tranſlated from the Italian into the Latin language. Colvius was intimately acquainted with many literary characters of his own age, and was himſelf a philoſopher and poet of eminence, but he is chiefly known as a collector of rarities of every deſcription, of which, in the year 1655, he publiſhed a catalogue intitled "Catalogus Muſcei And. Colvii." He died at Dort in 1671. Moreri.

COLYBA, or Colybus, a term in the *Greek Liturgy*, ſignifying an offering of corn and boiled pulſe, made in honour of the ſaints, and for the ſake of the dead.

Balſamon, P. Goar, Leo Allatius, and others, have written on the ſubject of *colybæ*: the ſubſtance of what they have ſaid, is as follows:

The Greeks boil a quantity of wheat, and lay it in little heaps on a plate; adding beaten peas, nuts cut ſmall, and grape-ſtones, which they divide into ſeveral compartments, ſeparated from each other by leaves of parſley. A little heap of wheat, thus ſeaſoned, they call κολυβα.

They have a particular formula for the benediction of the colybæ: wherein, praying that the children of Babylon may be fed with pulſe, and that they may be in better condition than other people, they deſire God to bleſs thoſe fruits, and thoſe who eat them, becauſe offered to his glory, to the honour of ſuch a ſaint, and in memory of the faithful deceaſed. Balſamon refers the inſtitution of this ceremony to St. Athanaſius; but the Greek Synaxary to the time of Julian the Apoſtate.

Many of the Latin divines having ſpoken injuriouſly of this ceremony, Gabriel archbiſhop of Philadelphia, has written a diſcourſe in its vindication: wherein he endeavours to ſhew that the deſign of the colyba is only to repreſent the reſurrection of the dead, and to confirm the faithful in the belief thereof. The colybæ, he ſays, are ſymbols of a general reſurrection; and the ſeveral ingredients added to the wheat, ſignify ſo many different virtues.

COLYBRASSENSIS, in *Ancient Geography*, an epiſcopal ſee of Africa, in Pamphylia, according to the acts of the council of Conſtantinople, held in the year 381.

COLYMBIS, in *Ornithology*. Bellonius deſcribes the tufted duck *anas fuligula* of modern writers under the name of *colymbis*.

COLYMBUS, a genus of the *anſeres*, having the bill toothleſs, ſubulate, ſtraight, and pointed; throat denticulated; noſtrils linear, and ſituated at the baſe of the bill; legs fettered.

Linnæus includes in the *colymbus* genus three families of birds; the guillemot, the divers, and the grebes, each of which, in the opinion of moſt ornithologiſts, ought to be conſidered generically diſtinct. The guillemots live chiefly cloſe to the ſea, and inhabit rocks; they have a ſlender tongue the ſize of the bill, and the bill itſelf of a compreſſed form, with the upper mandible a little bent, and the baſe covered with ſhort feathers; they are principally diſtinguiſhed by having the feet three-toed. The divers have a ſtrong bill, leſs pointed, cylindrical, the edges of the mandible turned in, the upper one longeſt; noſtrils divided in the middle by a membrane tongue long, ſharp, ſerrated at the baſe each ſide; legs ſlender; tail-feathers twenty in number; the chief character of theſe conſiſt in the feet being furniſhed with four toes, and palmate; they frequent freſh waters. The grebes are without a tail, have a ſtrong bill; lores naked; tongue a little cleft at the tip; body depreſſed, and thickly covered with ſoft ſhining plumage; wings ſhort, and the legs compreſſed; the principal characteriſtic of this family are the lobate feet; conſiſting of four toes each. Thoſe laſt mentioned birds frequent meres, and other inland watery places.

* *Feet three-toed*, Guillemot.

Marmoratus. Above ſtreaked with cheſnut and brown;

beneath waved with duſky and white; legs tawny; bill, tail, wings, and claws black. *Colymbus marmoratus*, Gmel. *Marbled guillemot*, Lath. Syn. *Uria marmorata*, Lath. Ind. Orn.

Inhabits the weſtern parts of America and Kamtſcatka. This bird is ten inches in length; the crown is duſky; ſome of the greater quill-feathers edged with white; chin duſky, with white ſtripes.

Lacteolus. Snowy; bill and legs browniſh fleſh-colour. *Colymbus lacteolus*, Gmel. *Cepphus lacteolus*, Pallas Spic. *White guillemot*, Lath. Gen. Syn. *Uria lacteola*, Lath. Ind. Orn.

Lives on the ſea-coaſts, and chiefly inhabits the Netherlands. A variety of this bird is deſcribed by writers (Sander Naturſ. &c.) that has a black ſpot on each ſide behind the eyes; interſcapulars and area of the wings black; upper mandible black, the lower yellowiſh.

Grylle. Body deep black; wing-coverts white. *Colymbus grylle*, Linn. Gmel. *Colymbus groenlandicus*. Klein. *Uria minor nigra*, Briſſ. &c. *Greenland dove, ſea turtle*, Albin. *Black guillemot*, Lat. Donov. Brit. Birds, &c.

A general inhabitant of Europe and America, frequenting the ſea-coaſt, and preying on fiſh; it builds its neſt on the ground, the eggs are whitiſh, and ſpotted with black. This ſpecies is liable to ſome variation in the diſpoſition of its ſpots, and appearance of plumage. One variety found at Aoonalaſhka is of a ſooty black colour, with a double white band. Another is ſtreaked above; beneath white, banded with cinereous; upper wing-coverts varied with white and black; this is the *uria balthica* of Brunnich, and inhabits Greenland. A ſecond variety mentioned by the ſame author has the back, wings, and tail black; head, neck, and body beneath, with the ſpot on the wings white. Dr. Latham deſcribes a variety from Kamtſchatka of a black colour, with the crown clouded; the greater wing-coverts, and under ſide of the body, varied with white and black; throat entirely white; and laſtly, the *uria grylloides* of Brunnich is conſidered by ſome as a variety of this ſpecies; the upper part of the plumage of this bird is ſpotted white and black, the colour beneath white.

Troile. Body black; breaſt and abdomen ſnowy; ſecondary wing-feathers white at the tip. *Colymbus troile*, Linn. *Lomwia hoieri*. Ray. *Le guillemot*, Buff. *Lumme*, Marten Spitſ. *Fooliſh guillemot*, Penn. Donov. Brit. Birds, &c.

This bird inhabits Europe and America, and is found in maritime ſituations, as its principal food conſiſts of ſea-fiſh; its uſual reſorts are the ſteepeſt and moſt inacceſſible cliffs on the ſea-coaſt, and in ſuch places is ſeen in vaſt numbers on our own coaſts during the ſummer, in which ſeaſon they breed. The places moſt celebrated as the reſort of thoſe birds are the iſle of Prieſtholm, in Beaumaris bay, between Caernarvonſhire and the iſland of Angleſea; on a rock called Godreve, not far from St. Ives, Cornwall; the Farn iſland, near the coaſt of Northumberland; and the cliffs about Scarborough, Yorkſhire. They are ſilly birds, and ſo ſtupid, that having once attained acceſs to their haunts, they may be knocked down in any numbers with a ſtick, for though they ſee their companions killed before them, they never attempt to quit the rocks. In many parts they are killed by the inhabitants both for the ſake of their fleſh and ſkin; the former is, however, not remarkable for its delicacy, and has a ſtrong fiſhy taſte. The natives of Greenland and Kamtſchatka make garments of their ſkins. Like the auk, this bird lays but a ſingle egg; the eggs are in more eſteem for the table than the fleſh. The length of this bird is ſeventeen inches. There are ſeveral varieties of this ſpecies.

We have followed the example of Linnæus and Gmelin in conſidering the four above-mentioned birds as appertaining to the *colymbus* genus, but it ſhould be at the ſame time obſerved, that Brunnich conſtitutes a diſtinct genus of them under the title of *uria*, and that this genus is adopted by Dr. Latham, in his "Index Ornithologicus," though he adheres to the Linnæan method in his "General Synopſis."

** *Feet four-toed, palmated*, Diver.

Glacialis. Head and neck violaceous black; a white interrupted band on the chin and upper part of the neck. *Colymbus glacialis*, Linn. *Colymbus torquatus*, Brun. *Mergus nævius*, Briſſ. *Colymbus maximus caudatus*, Ray. *L'Imbrina*, Buff. *Greateſt ſpeckled diver* or *loon*, Albin. *Northern diver*, Penn. Donov. Brit. Birds.

This is a large bird, meaſuring about three feet in length; the upper part of the body with the bill, legs, and tail are black; the back and upper part of the wings is marked with a number of white ſpots diſpoſed in rows. Inhabits the Northern ſeas, and is rare in England. The ſpecimen in the London Muſeum.

In Iceland and Greenland, where thoſe birds breed, they are very frequent. It is alſo abundant on the ſhores of Norway, and along the Arctic coaſts as far as the river Obey, in the dominions of Ruſſia. It is ſeldom ſeen on land, except in the breeding ſeaſon, being, for the moſt part, in the open ſea, where it is continually diving for fiſh, which it does with the greateſt addreſs. Among the northern maritime nations, the ſkins of thoſe birds are prepared by the natives, and manufactured with the feathers on them into caps and other articles of dreſs. Garments, we are told, made of theſe ſkins are warm, and never imbibe the leaſt moiſture, and are alſo more durable in wear than might be imagined. The bird is likewiſe met with among the lakes of Hudſon's bay, where the natives adorn their heads with circlets of their feathers.

Immer. Body above blackiſh, undulated with white; beneath entirely white. *Colymbus immer*, Linn. *Mergus major*, Briſſ. *Le grand plongeon*, Buff. *Ember gooſe*, Sibbald. *Imber diver*, Penn. Donov. Brit. Birds.

The length of this bird is two feet; the feathers of the back, wings, and tail are edged with white; in the male bird the front and ſides of the head and neck are ſpotted with brown. This ſpecies inhabits the Arctic ocean; it ranks as a Britiſh ſpecies, but is rarely taken in our country.

Stellatus. Cinereous-brown or duſky, ſpotted with white; throat pale aſh, beneath white. *Colymbus ſtellatus*, Brun. Gmel. *Mergus minor*, Briſſ. *Colymbus caudatus ſtellatus*, Will. *Le petit plongeon*, Buff. *Speckled diver*, or *loon*, Lath.

Obſerved in plenty about the ſhores of the Baltic, and white ſea, and in America. They occaſionally migrate in flocks, purſuing the ſame courſe as the ſhoals of herrings and ſprats, the latter in particular, and it is for this reaſon known in many parts by the name of *ſprat loon*. Theſe birds are more common in the temperate, or ſouthern parts of Europe, than any other of the diver tribe. The length is twenty-ſeven inches, the bill horn colour; legs brown. It builds no neſt, but lays its eggs, which are two in number, in the graſs on the borders of lakes contiguous to the ſea-coaſt; thoſe eggs are duſky, ſpotted with black.

ARCTICUS. Head hoary; neck beneath violaceous, black, with an interrupted white band. *Colymbus arcticus*, Linn. *Mergus gutture nigro*, Briſſ. *Black-throated diver*, Lath.

Length two feet; inhabits the north of Europe, Aſia, and America.

SEPTENTRIONALIS. Body above blackiſh, beneath white; neck beneath with a ſhield-like ſpot. *Colymbus ſeptentrionalis*, Linn. *Mergus gutture rubro*, Briſſ. *Le plongeon à gorge rouge*, Buff. *Red throated diver*, Lath. Donov. Brit. Birds, &c.

Inhabits Europe, Aſia, and America, frequenting lakes, and oftentimes the open ſea in queſt of prey, which conſiſts of fiſh, marine inſects, and crabs. The body is brown above, with minute white ſpots, beneath white; bill black, head and chin cinereous, ſpotted with brown; neck above with ſmall white and brown lines; the legs duſky. Length about thirty inches. Theſe birds lay their eggs in June, the young are hatched and ready to fly before the end of Auguſt, and undertake their annual migrations with the parent birds in September. They breed chiefly in America.

BOREALIS. Body above blackiſh, with numerous white ſtellated ſpots; beneath white; neck on the fore-part rufous. *Colymbus borealis*, Brun.

This bird was ſhot near Copenhagen; it reſembles in ſize and appearance *colymbus ſtellatus*, and is, perhaps, a variety of that bird. Brunnich conſiders it as a diſtinct ſpecies.

STRIATUS. Blackiſh, beneath white; head and neck grey, lineated with black. *Colymbus ſtriatus*, Gmel. *Striped diver*, Lath.

Inhabits North America, where it frequents lakes; it is repreſented as a noiſy clamorous bird, and one continually in motion or on the wing, flying backwards and forwards. The bill of this ſpecies is duſky, or black, and ſtrong; the cheeks white.

SINENSIS. Greeniſh-brown, with deeper ſpots; breaſt and belly reddiſh-white, ſpotted with rufous; wings and tail blackiſh. *Colymbus ſinenſis*, Gmel. *Chineſe diver*, Lath.

This ſpecies inhabits China, and is ſuppoſed to be one of thoſe kinds of aquatic birds which are trained up, and employed by the Chineſe for catching fiſh. The bill is duſky; and the irides and legs cinereous.

*** *Feet four-toed, and lobed.* Grebe.

CRISTATUS. Fuſcous, beneath white; head rufous; collar black; ſecondary quill-feathers white. *Colymbus criſtatus*, Linn. *Colymbus cornutus*, Briſſ. *Le grebe cornu*, Buff. *Creſted grebe*, Lath.

Length of this ſpecies twenty-three inches; bill fleſh-colour, with the tip brown, beneath white; head tumid, varies in colour by age, and has been deſcribed in the firſt, ſecond, and third years' plumage, as three diſtinct ſpecies.

Like the reſt of the grebe tribe, theſe birds form a floating neſt, compoſed of graſs and flags, interwoven with the roots and ſtalks of other aquatic plants. The female lays four eggs, which are of a white colour, and ſits in the neſt half immerſed in water till the eggs are hatched. It preys on eels and fiſh, which it procures with great facility, by diving into the water. The fleſh is rank, but the ſkins, which are prepared with the beautiful ſilken and ſilvery white plumage on them are in high requeſt for muffs and tippets. Many of the grebes are taken on the lakes of Geneva for that purpoſe. In England, thoſe birds frequent the meres of Shropſhire and Cheſhire, and the great fens of Lincolnſhire, in all which places they are known to breed. The tippet grebe is ſaid to be the young of this ſpecies.

CAYANUS. Blackiſh brown, beneath white; under ſide of the neck rufous. *Colymbus cayennenſis*, Gmel. *Le grande grebe*, Buff. *Grebe de Cayenne*, Pl. Enl. *Cayenne grebe*, Lath.

A native of Cayenne. This bird is nineteen inches and a half in length; the bill and legs are duſky; and the lower mandible yellow at the baſe.

AURITUS. Blackiſh-fuſcous, beneath white; neck beneath rufous. *Colymbus auritus*, Linn. *Le petit grebe*, Buff. *Duſky grebe*, Penn. Donov. Brit. Birds.

Inhabits fenny places in Europe and America. Length eleven inches. The bill is black, and red at the ſides; irides and lores purple; upper edge of the wings white; legs fleſh-colour, inclining to purple.

CORNUTUS. Head gloſſy-green, and tumid; neck beneath, and breaſt fulvous; through the eyes a yellow tufted band. *Colybus coruutus*, Gmel. *Horned grebe*, Arct. Zool.

An inhabitant of Hudſon's bay; length twelve inches. Dr. Latham deſcribes the little horned grebe, *le petit grebe cornu* of Buffon as a variety of this ſpecies.

RUBRICOLLIS. Somewhat creſted; chin, cheeks, and regions of the ears aſh-coloured; neck beneath, and breaſt ruſty red; belly and ſecondary quill feathers white. *Colymbus rubricollis*, Gmel. *Colymbus ſubcriſtatus*, Jacq. *Le grebe à joues griſes jougris*, Buff. *Red necked grebe*, Lath. Donov. Brit. Birds.

The length of this bird is eighteen inches; the bill is duſky, and at the ſides at the baſe tawny; the legs duſky. This is a Britiſh ſpecies; the male is very rare, the female ſcarcely known; both ſexes are preſerved in the London Muſeum.

CASPICUS. Head ſmooth; body above dark brown, beneath ſilvery; bill lead colour; chin and cheeks white; wing-coverts brown. S. G. Gmel. Inhabits near the Caſpian ſea.

THOMENSIS. Fuſcous; beneath white, ſpotted with grey; quill-feathers pale rufous; breaſt with a black ſpot. *Colymbus thomenſis*, Gmel. *Le grebe duc-laart*, Buff. *Black-breaſted grebe*, Lath.

Leſs than the common hen; the bill is black, with the tip pale; irides and ſpot between the bill and eyes white; legs duſky. Inhabits St. Thomas's iſland in America.

MINOR. Fulvous brown; beneath, ſpot on the quill-feathers, and lower part of the rump, ſilvery white; neck beneath tawny grey. *Colymbus minor*, Gmel. *Podiceps minor*, Ray. *Little grebe*, Lath. Donov. Brit. Birds.

This bird inhabits Europe and America, is ten inches in length, and feeds on worms, ſmall fiſh, and aquatic inſects. Buffon deſcribes a variety of it under the title of "Le Caſtagneuz des Philippines;" it is larger than the former, the plumage above purple brown; and the cheeks and ſides of the neck reddiſh. Found in the Philippine iſles.

DOMINICUS. Head ſmooth; body beneath thickly ſpotted. *Colymbus dominicus*, Linn. *Le caſtagneux de St. Domingue*, Buff. *White-winged grebe*, Lath.

Inhabits the Antilles and Surinam. Its length is eight inches; the bill is black; body duſky, beneath ſilvery grey; quill-feathers cinereous white; legs brown.

HEBRIDICUS. Head ſmooth; body blackiſh; chin black; throat ſub-ferruginous; belly cinereous, mixed with ſilvery. *Colymbus hebridicus*, Gmel. *Black-chin grebe*, Lath.

A ſmall and rare ſpecies, found chiefly in Tiree, one of the iſlands of the Hebrides.

Podiceps. Body fuſcous; bill olive, duſky at the baſe, with a tranſverſe black band in the middle. *Colymbus podiceps*, Linn. *Le caſtagneux à bec circlé*, Buff. *Pied bill grebe*, Lath.

A native of North America; length fourteen inches; irides white; chin black, ſurrounded with white; body beneath ſilvery; breaſt waved with cinereous; ſecondary quill-feathers black at the tip. The female has no black mark on the bill.

Ludovicianus. Fuſcous; ſides of the neck and body ferruginous; beneath white, with tranſverſe blackiſh ſpots. *Colymbus ludovicianus*, Gmel. *Le grebe de la Louſiane*, Buff. *Louſiane grebe*.

Inhabits Louſiane. The head is ſmooth; legs duſky; middle of the belly ſilvery white.

COLYTON, or Culliton, in *Geography*, is a ſmall but ancient market town in Devonſhire, England. It is called by Riſdon, a "borough of reputation:" the houſekeepers of a ſmall diſtrict, called the borough, annually choſe a portreve at the lord's court. At the Norman conqueſt, Colyton was the king's demeſne; and king John granted the inhabitants a fair, to continue eight days. The houſes are in general built with flints and moſtly thatched. The pariſh church is a ſpacious ſtone fabric, with a tower riſing above the chancel, the upper part of which is octagonal. On the ſouth ſide of the chancel is an incloſed burial-place, belonging to the De la Pole family, containing various effigies, and other monumental decorations: and in a ſmall aiſle adjoining, is the figure of a girl, apparently about five years of age, under a canopy of ſtone; ſhe is ſaid to have been the grand-daughter of Edward IV., and to have been choked by a fiſh-bone; over her are the royal and Courtenay arms. Colyton arms is ſituated 153 miles S.W. from London: the number of houſes is 289; of inhabitants 1641.

COLYTTUS, or Collytus, in *Ancient Geography*, the name of a quarter of the city of Athens, belonging to the Egeide tribe, and adjoining to that called Melitos.

COM, or Kom, in *Geography*, one of the oldeſt, and formerly of the largeſt towns of Perſia in the province of Irak Agemi. It has ſuffered greatly by the civil wars with which the Perſian empire has been ſo often diſtracted, but is ſtill a very populous place; 90 miles S. of Caſbin, and 150 N. of Iſpahan. It is celebrated for its ſilk manufactures, chiefly velvet. N. lat. 34°. E. long. 50°.

COMA. See Como.

Coma, in *Medicine*, a preternatural propenſity to ſleep, though the patient frequently does not ſleep, or if he does, awakes without relief. If ſleep enſues, the diſeaſe is called *coma ſomnolentum*; in this caſe the patient continues in a profound ſleep, and when awaked, immediately relapſes, without being able to keep open his eyes. If he does not ſleep, but is continually awakened with frightful dreams, it is called *coma vigil*: in this caſe he appears to ſleep, having his eyes conſtantly ſhut. Coma is produced by debility, by the want of food, exerciſe, &c. See Apoplexy.

Coma, in *Botany*, from κομη, *a head of hair*, is applied to a leafy crown, whether of the proper leaves of the plant, or of bracteas, riſing above the fructification. In the pine-apple and crown imperial it is of the former kind; in *ſalvia horminum*, or purple topped clary, of the latter, being moreover elegantly coloured with pink or purple. See Comose.

Coma *aurea, africana frutefcens foliis anguſtiſſimis trifidis*, Burm. See Athanasia *erithmifolia*.

Coma *africana frutefcens, foliis inferioribus inciſis*, Comm. See Athanasia *dentata*.

Coma *africana fruticans ericæ folio*, Comm. See Chrysocoma *ciliaris*.

Coma *africana fruticans, foliis erithmi marini*, Comm. See Athanasia *erithmifolia*.

Coma *africana fruticans foliis glaucis & in extremitatibus trifidis*, Comm. See Athanasia *triſurcata*.

Coma *africana fruticans foliis linariæ, major*, Comm. See Chrysocoma *cernua*.

Coma *africana fruticoſa omnium maxima*, Comm. See Athanasia *pubeſcens*.

Coma *foliis multifidis glaucis*, Burm. See Athanasia *parvifolia*.

Coma *Berenices*, *Berenice's Hair*, in *Aſtronomy*, a modern conſtellation of the northern hemiſphere; compoſed of unformed ſtars between the Lion's tail and Bootes.

This conſtellation is ſaid to have been formed by Conon, an aſtronomer, in order to conſole the queen of Ptolemy Euergetes, for the loſs of a lock of her hair, which was ſtolen out of the temple of Venus, where ſhe had dedicated it on account of a victory obtained by her huſband. Ricciol. Alm. lib. vi. cap. 4.

The ſtars in the conſtellation Coma Berenices, in Tycho's Catalogue, are 14; in Hevelius's, 21; and in the Britannic Catalogue, 43.

COMACENUS Lacus, in *Ancient Geography*, the lake of *Como*, which ſee.

COMACHIO, in *Geography*, a ſmall town of Italy, the ſee of a biſhop, in the Ferrareſe, ſurrounded by ſalt marſhes, which render the air inſalubrious, and inhabited chiefly by fiſhermen; 33 miles S.E. of Ferrara. N. lat. 44° 32'. E. long. 12° 6'.

COMACLUM, in *Ancient Geography*, a town of Venetia.

COMAGENA. See Commagene.

COMAGENÆ, a place of Norica, diſtant, according to Antonine's Itinerary, 24 miles from mount Cetius.

COMANA, a town of Pontus, ſeated on the river Iris, towards the mountain of Paryadræ, on the ſouth. It was famous for a temple of Bellona. The town and territory depended on a pontiff, who, on ſolemn days, wore a diadem, and poſſeſſed a kind of ſovereignty. Venus alſo was worſhipped in this city; her feaſt was celebrated with great magnificence, and ſhe had many courtezans.

Comana, a town of Aſia, in the greater Cappadocia, ſeated on the river Sarus, in Cataonia. It was alſo called *Chryſe*, and bore the appellation of Cappadocian.

Comana, or *Bocana*, a town of the iſland of Taprobana, according to Ptolemy.

Comana, or *Commacus*, a town of Aſia, in Piſidia.—Alſo, another town in Phrygia. Ptolemy.

Comana, in *Geography*, a town of South America, in the northern diviſion of Terra Firma. It lies on the north-eaſternmoſt part of the ſea-coaſt.

COMANCHES, or Hietans, a tribe of Indians in Louiſiana in America, who have no fixed place of reſidence, and who have neither towns nor villages. They are divided into ſo many hordes, that they have ſcarcely any knowledge of one another. They never continue in the ſame place for more than a few days, but follow the buffalo, the fleſh of which is their principal food. Some of them purchaſe of the Panis or Towiaches, another tribe, corn, beans, and pumpkins; but their number is ſo great, that theſe articles furniſh a ſmall quantity of their food. Their tents are made of ſkins neatly dreſſed, and faſhioned in the form of a cone, affording room for a family of 10 or 12 perſons; thoſe of the chiefs are capable of accommodating 50 or 60 perſons. When they pitch their tents, they form regular ſtreets and ſquares, exhibiting a ſort of town ſuddenly raiſed, as it were by inchantment, and at a ſignal for march, they are as ſuddenly ſtruck: to every tent are allotted two horſes or mules, one for carrying the tent, and another for removing the poles or ſticks, which are neatly made of red cedar; they all travel on horſeback. Their horſes are tied for grazing with a long halter, and they are ſo numerous as to require frequent change of place. Their horſes are ſo managed, as to be remarkably docile and gentle. It is their practice to hunt the buffalo on horſeback; and they kill this animal with the bow, or a ſharp ſtick like a ſpear, which they carry in their hands. They are generally at war with the Spaniards, committing frequent depredation upon the inhabitants of Santa Fé and St. Antoine; but they have been always friendly and civil to any French or Americans who have been amongſt them. With regard to their perſons, they are ſtrong and athletic, and, in advanced life, corpulent. As ſavages, they are uncommonly clean: the dreſs of their women is a long looſe robe, reaching from the chin to the ground, tied round with a fancy ſaſh or girdle, all neatly made of dreſſed leather, on which they paint figures of different colours and ſignifications: the dreſs of the men conſiſts of cloſe leather pantaloons, and a hunting ſhirt, or frock of the ſame. Their continuance in the ſame place does not admit of their making any plantation; but the ſmall Cayenne pepper grows ſpontaneouſly in the country, and with this, together with ſome wild herbs and fruits, particularly a bean that grows plentifully on a ſmall tree, reſembling a willow, called Maſketo, the women cook their buffalo beef in a manner that renders it grateful food. They alternately occupy the immenſe ſpace of country from the Trinity and Braces, croſſing the Red river, to the heads of Arkanſa and Miſſouri, to river Grand, and beyond it, about Santa Fé, and over the dividing ridge on the waters of the Weſtern Ocean, where, as they ſay, they have ſeen veſſels, which they deſcribe as ſhips, with ſails and rigging. Their native language differs from that of any other nation; but they have a mode of making themſelves underſtood to all the Indians by ſigns. Among them are many Spaniſh men and women, who are ſlaves, and who were made priſoners by them in their youth.

COMANI, in *Ancient Geography*, a people of Aſia, probably of Scythia, who inhabited the country Comania, mentioned by Pliny. They were probably the ſame with the Comi of Ptolemy, and the Comari and Coamani, placed by Pomponius Mela in the vicinity of the Paropaniſians.

COMANIA, a country of Aſia, according to Xenophon. See COMANI.

COMANIA, alſo called *Dagheſtan*, a country in the northern part of Turkey in Aſia, ſouth from Little Tartary, and north from Georgia bounded on the eaſt by the Caſpian ſea, W. by the Caucaſus, N. by Circaſſia, and S. by Skirvan. Its inhabitants are known by the name of Comoucks. See DAGHESTAN.

COMANNA, an inland country of Africa, on the Slave coaſt, bounded on the eaſt by Inſoko, on the ſouth by Lobadde and Ningo, two provinces of Aquamboe; its northern limit is unknown. Little is known of the country, except that its natives bring great quantities of gold to the markets of Akkaradi, a kingdom touching it on the weſt, who afterwards carry it to Aboni, and thence to the negroes of the ſea-coaſt. Beyond Comanna, in regular ſucceſſion from E. to W. but with unaſcertained boundaries to S. and N., are the kingdoms of Latabi, Equea, Bonu, ſituated far north: Taſu, Quako, Aboni, Sankug, Agua, and Achem, all ſuppoſed to be rich in gold; but more eſpecially Quako.

COMARCHIOS, in *Antiquity*, the name of a particular air, or tune, deſigned to be ſung at entertainments.

COMARGO, in *Geography*, a town of North America, in New Leon, ſituate on the ſouth ſide of Rio Bravo, which empties itſelf into the gulf of Mexico on the weſt ſide.

COMARIA PROMONTORIUM, in *Ancient Geography*, a maritime place of India, at the extremity of the peninſula, on this ſide of the Ganges. Ptol. See *Cape* COMORIN.

COMARIS, in *Lithology*, a name given by the Greek writers to the *ſelenites*, or *aphroſelene*.

COMAROIDES, in *Botany*, *alpina argentum*; Segui. See POTENTILLA *nitida*.

COMARTCH, in *Geography*, a river of South Wales, in the county of Brecknock, which runs into the Yrvon, eight miles W. of Builth.

COMARUM, in *Botany*, (Κομαρος,, a name given by Theophraſtus to an evergreen tree, ſuppoſed to be an arbutus.) Linn. Gen. 638. Schreb. 869. Willd. 1004. Gært. 451. Vent. 3. 347. (Pentaphylloides; Tourn.) Claſs and order, *iſocandria polygynia*. Nat. Ord. *Senticoſæ*, Linn. *Roſaceæ*, Juſſ. Vent.

Gen. Ch. *Cal.* Perianth one-leafed, ten cleft, very large, ſpreading, coloured, permanent; alternate ſegments ſmaller, inferior. *Cor.* Petals five, oblong, acuminate, inſerted on the calyx, much ſmaller. *Stam.* Filaments about twenty, awl-ſhaped, inſerted into the calyx, length of the corolla, permanent; anthers creſcent-ſhaped, deciduous. *Piſt.* Germs numerous, roundiſh, very ſmall, collected into a head; ſtyles ſimple, ſhort, from the inſide of the germ; ſtigmas ſimple. *Peric.* none. *Seeds* naked, even-ſurfaced; attached to a large, egg-ſhaped, ſpongy, villous, perſiſting receptacle.

Eſſ. Ch. Calyx ten-cleft, inferior. Petals five, leſs than the calyx. Receptacle egg-ſhaped, ſpongy, villous, perſiſting. Seeds even-ſurfaced.

Sp. C. *paluſtre.* Marſh cinquefoil. Linn. Sp. Pl. Mart. Willd. Flor. Dan. tab. 636. Lam. Ill. tab. 444. Eng. Bot. tab. 172. (Quinquefolium rubrum; Bauh. Pin. 326. Pentaphyllum paluſtre; Cord. Hiſt. 96. 1. Fragaria, Hall. Helv. n. 1128. Potentilla; Scop. Carn. n. 617.) *Root* creeping. *Stems* decumbent at the baſe, cylindrical, leafy, ſmooth. *Leaves* on long petioles, quinate-pinnated; leaflets on ſhort petioles, oblong, ſerrated, hoary underneath; ſtipules embracing the ſtem. *Flowers* dark purple, ſomewhat panicled; peduncles one-flowered, bractes two, lanceolate; ſtamens, anthers, ſtyle, and receptacle, nearly black. A native of England, and moſt other parts of Europe in boggy ground, and by the ſides of ponds. There is a variety with thicker and more villous leaves, but Miller aſſures us that after one year's growth in a garden it is not to be diſtinguiſhed from the common ſort.

COMARUS PORTUS, in *Ancient Geography*, a name given by Dion Caſſius to a port of Epirus, which he places in the gulf of Ambracia. Strabo calls it Comarus Sinus, and makes it a ſmall gulf of Epirus.

COMAYUAGUA, or VALLADOLID, in *Geography*, a large town of the province of Honduras, in Old Mexico, or New Spain, in North America, on a river which falls into the gulf of Honduras. It is the ſee of a biſhop, and has rich ſilver mines in its neighbourhood; 90 miles S.E. of Truxillo. E. long. 88° 4′. N. lat. 14° 30′.

COMB, an inſtrument made of horn, ivory, tortoiſe-ſhell, box, or holly-wood, &c. and uſeful for ſeparating and adjuſting the hair, &c.

Comb *making*. Combs are not only made for the purpoſe of cleaning the hair, but for ornament: they are ſometimes ſet with brilliant ſtones, pearls, and even diamonds; ſome again are ſtudded with cut ſteel; theſe are of different ſhapes, and are uſed to faſten up the hair when ladies dreſs without caps. Combs may of courſe be had of all prices, from the value of a few pence to almoſt any ſum. They are generally made of the horns of bullocks or of elephants, and ſea-horſes teeth, and ſome are made of tortoiſe-ſhell and ivory, others of box or holly-wood. The horns of bullocks are thus prepared for this manufactory: the tips are firſt ſawn off; they are then held in the flame of a wood fire, this is called roaſting, by which they become nearly as ſoft as leather. While in that ſtate they are ſlit open on one ſide, and preſſed in a machine between two iron plates; they are then plunged into a trough of water, from which they come out hard and flat; they are then ſawn into lengths, according to the ſize wanted. To cut the teeth, each piece is fixed into a tool called a claw. The maker ſits on a triangular ſort of a ſtool to his work, and under him is placed the claw that holds the horn, ivory, &c. that is to be formed into a comb. The teeth are cut with a fine ſaw, or rather a pair of ſaws, and they are finiſhed with a file. A coarſer file, called a raſp, is uſed to reduce the horn, &c. to a proper thickneſs; and when they are completely made, they are poliſhed with charcoal and water, and receive their laſt finiſh with powder of rotten ſtone. The proceſs uſed for making ivory combs is nearly the ſame as that already deſcribed, except that the ivory is firſt ſawed into thin ſlices. The beſt ivory comes from the iſland of Ceylon and Achen in the Eaſt Indies, as it poſſeſſes the property of never turning yellow; it is conſequently much dearer than any other kind.

Tortoiſe-ſhell combs are much eſteemed; and there are methods of ſtaining horn, ſo as to imitate it, of which the following is one: the horn to be dyed is firſt to be preſſed into a flat form, and then done over with a paſte, made of two parts of quick-lime and one of litharge, brought into a proper conſiſtence with ſoap-ley. This paſte muſt be put over all the parts of the horn, except ſuch as are proper to be left tranſparent, to give it a nearer reſemblance to tortoiſe-ſhell. The horn muſt remain in this ſtate till the paſte be quite dry, when it is to be bruſhed off. It requires taſte and judgment ſo to diſpoſe the paſte, as to form a variety of tranſparent parts, of different magnitudes and figures, to look like nature. Some parts ſhould alſo be ſemi-tranſparent, which may be effected by mixing whiting with a part of the paſte. By this means ſpots of a reddiſh brown will be produced, ſo as greatly to increaſe the beauty of the work. Horn thus dyed is manufactured into combs, and theſe are frequently ſold for real tortoiſe-ſhell. The wages of journeymen in this buſineſs are from 21*s.* to 31*s.* per week.

In *Plate* XV. of *Mechanics* is repreſented a machine for cutting combs, for which Mr. William Bundy, of Pratt Place Camden Town, took out a patent in the year 1796, and the ſame is deſcribed in the Repertory of Arts. The frame A A. *fig.* 3 of the machine, is like a common lathe, containing a ſpindle, with a crank and fly-wheel, D, upon it, turned by the alternate motion of the treadle, B, which is moved by the workman's foot; E is a wheel fixed on the crank ſpindle, carrying a line in its groove, croſſing between the cheeks of the lathe, and paſſing over the pulley, F, which turns on a centre fixed in the puppet, G; it has two holes in it to receive the horned catch, *a*, *fig.* 2, ſcrewed on the end of an arbor, *b*, about ſeven inches in length, and half an inch in diameter; this arbor is mounted between two circular braſs plates, H, I, *fig.* 1, connected by three pillars, it carries as many circular ſteel cutters, or ſaws, K, *fig.* 4, as the comb to be cut is to have teeth. M, *fig.* 5, repreſents another arbor, which is fixed in the frame-plates, *fig.* 1, by its ends; it is triangular, and has a piece of ſteel, L, *fig.* 4 (called a guide), fitted on it between each ſaw, on the arbor, *b*. Theſe parts are put together by firſt putting the end of the arbor, *b*, *fig.* 2, through the hole in the centre of the frame-plate, I, and ſcrewing on the catch, *a*; the end of the arbor, *fig.* 5, is put into a ſquare hole made in the plate, I, to receive it, and is fixed by a ſcrew; a guide, L, *fig.* 4, is then put on the arbor, M, cloſe againſt the ſhoulder, *d*; next a cutter, K, is put on the arbor, *b*, touching its ſhoulder, *e*; a piece of ſteel plate, N, called a guide-waſher, is then put on the arbor, M, and another guide, L, cloſe to it; the guide-waſher is a little thicker than the cutter oppoſite it, ſo that the cutters each turn between two guides without touching them. Theſe being in their places, a ſmall waſher, O, *fig.* 4, is put on the arbor, *b*, and a cutter, then a guide-waſher and guide, on the arbor, M, and ſo on alternately, till the right number of cutters are put on; the ſliding ſhoulder, *f*, *fig.* 2, is then taken, and with the octagonal nut, *g*, ſcrewed faſt up againſt the laſt cutter, put on the arbor, *b*, this will pinch all the cutters and waſhers between the ſhoulders, *e* and *f*, and hold them faſt. The ſame is done to the arbor of the guides, and, laſtly, the frame-plate, H, is put on the ends of the pillars, and ſcrewed faſt; the whole forming the reſemblage ſhewn in *fig.* 1. The frame-plates with the arbors, as in *fig.* 1, are now to be put in their place in the machine, *fig.* 3, the horns of the catch, *a*, going into two holes in the pulley, F, and the other end of the arbor, *b*, into a centre that goes up with a ſcrew in the puppet, Q; the ſcrews, *h*, *h*, are deſigned to ſteady the frame-plates (which hold the arbor of the guides) againſt the dove-tail, P P, ſupported by brackets projecting from the front of the cheeks, ſufficiently to let the block, *i*, which ſlides in the dove-tail, and holds the comb, be drawn forwards to give room for the hand to put in or take out the combs clear of the cutter. To the baſe of the dove-tail is ſcrewed a plate, holding one of the centres for a worm-wheel, *k*, whoſe axis is made of ſteel, and has its end cut with a deep thread-ſcrew; the ſcrew-end of this axis works in a centre, fixed to the baſe of the dove-tail, and the block, *i*, is cut away to paſs clear over it and the threads of the ſcrews, without touching them. The worm-wheel, *k*, is turned by an endleſs ſcrew, on the arbor of the wheel, *r*, which receives its motion from the pulley, *t*, by an endleſs line. The block, *i*, which holds the comb, moves in the dove-tail, and is to carry the comb towards the cutters while cutting. As the ſcrew on the axis of the wheel, K, is to carry the block up in lieu of a nut; a knife-edge, faſtened to a ſmall lever, *l*, moveable on a centre in the face of the block, is applied to it, and kept down (ſo that the knife-edge may take into the threads of the ſcrew) by a catch ſimilar to the latch of a door, which is releaſed by puſhing in a thumb-ſtud, and allows the ſpring, *o*, to throw up the lever, *l*, and diſengage the ſcrew, ſo that the block may be brought forwards in the dove-tail. The piece of ivory intended to be cut into a comb, is put under a plate, *p*, and held down by two ſcrews to the face of the block, which is in the ſame plane with the arbor of the cutters; the workman then puts down the knife-edge, and the catch keeps it ſo; he then turns the machine by his foot, and puſhes the block towards the cutters (the comb reſting cloſe on the guides) till the knife-edge take the firſt thread of the ſcrew, which turns round as before deſcribed, and puſhes the block and comb up to the cutters, as far as the

the ſcrew extends, and the cutters ſaw the teeth in the comb; the thumb-ſtud is then puſhed in, and the ſpring, *o*, throws the knife-edge up, ſo that the block can be brought back by hand, and the comb taken out. The diſtance which the comb projects from the face of the block towards the cutters, and conſequently the length of the teeth, is regulated by a ſtraight edge of metal on the top of the block, *i*, under the plate, *p*, againſt which the back of the comb reſts; it can be moved parallel to itſelf acroſs the top of the block by two ſcrews, (which are ſeen at the upper corners of the face of the blocks), for combs of longer or ſhorter teeth. The ſpindle of the crank has a wheel, R, on it, turning an arbor, S, by a line, which carries a ſet of cutters for pointing the combs. The arbor is ſhewn ſeparately in *fig.* 6, and a cutter in *fig.* 7; it is made up in the ſame manner as the former one, and faſtened by a ſcrew, T; the ends of the teeth of the comb are applied to this cutter by hand, firſt on one ſide, and then on the other, till the points are made. This is performed to one comb, while the teeth are cutting in another.

Comb, or *Coomb*, in *Huſbandry*, a meaſure of corn, conſiſting of 2 long ſtrikes = 4 Wincheſter buſhels = 16 pecks = 32 dry gallons = 128 dry quarts = 256 dry pints = 8601.6 cubic inches = 4.97 cubic feet = 1.843621 cubic yards = 17.32142 cubic links: in ſome places the buſhel contains eight gallons and a quart.

Comb, *Coomb*, or *Carnook*, of wheat, according to the 9th and 51ſt Henry III. 12th Henry VII., &c., was 256lb. troy = 210.6614lb. avoirdupoiſe = 2 ſtrikes = 16 pecks = 32 gallons = 256 pints or pounds.

Comb, in *Ornithology*, the creſt, or red fleſhy tuft growing on the head of a cock.

Comb, *in a ſhip*, a little piece of timber, ſet under the lower part of the beak-head near the middle: it has two holes in it, and ſupplies to the fore-tacks, what the cheſt-trees do to the main-tacks; that is to bring the main-tacks aboard.

Comb, in the *Manufacture of Tapeſtry*. See Tapestry.

COMB-MARTIN, in *Geography*, a town of England, on the north coaſt of Devonſhire, in the Briſtol channel, with a ſmall creek for boats; near it are ſilver-mines, which formerly yielded a conſiderable quantity of ore; 39 miles W. of Bridgewater, and 176 W. of London.

COMBA, in *Ancient Geography*, a town of Aſia Minor, in the interior of Lycia, and in the vicinity of mount Cragus. Ptolemy.—Alſo, a marſh of Greece, in Macedonia, near mount Athos, mentioned by Athenæus.

COMBAHEE, in *Geography*, a conſiderable river of South Carolina, which enters St. Helena Sound, between Cooſa and Aſhepoo rivers. The ferry of the ſame name on this river is diſtant 17 miles from Jackſon's borough; 15 from Pocotaglio, and 52 from Charleſtown.

COMBAM, or Commum, a town of Hindooſtan, in the country of Cuddapah; 65 miles N. of Cuddapah. Combam is reckoned 25 coſſes from Innaconda, and 32 from Ongole, or about 51 geographical miles from the latter. Tavernier calls it Kaman.

COMBAMET, a town of Hindooſtan, in the country of Golconda; 68 miles E. of Hydrabad.

COMBANA, or Nommana, in *Ancient Geography*, a town of Aſia, in Carmania, ſituated near the ſea.

CAMBARONES, in *Antiquity*, the fellow-barons or commonalty of the Cinque-Ports.

COMBAT, in a general ſenſe, denotes an engagement; or a difference decided by means of arms.

Authors ſometimes diſtinguiſh in an army, between a combat and a battle; the latter expreſſing the general action of the whole army; the former only a particular ſkirmiſh, or engagement of a ſingle part; ſo that the combat is properly a part of a battle.

Combat, in *Law*, or *ſingle combat*, denotes a formal trial, between two champions, of ſome doubtful cauſe or quarrel; by the ſword or batoons.

This form of proceeding was anciently very frequent, particularly among the barbarous nations in their original ſettlements; and obtained, not only in criminal, but alſo in civil cauſes; being built on a preſumption, that God would never grant the victory but to him who had the beſt right. It was originally permitted, in order to determine points reſpecting the reputation of individuals, but afterwards became much more extenſive. See Duel. The form and ceremony of the combat are deſcribed in the grand Coutumier of Normandy. The accuſer, firſt, ſwore to the truth of his accuſation; the accuſed gave him the lie: upon which, each threw down a gage, or pledge of battle; and the parties were committed priſoners to the day of combat. See Champion.

Hiſtorians tell us, that Alphonſus, king of Caſtile, in the eleventh century, deſiring to aboliſh the Moſarabic liturgy, and to introduce the Roman office; the people oppoſing it, it was agreed to terminate the difference by combat, and leave the cauſe to the deciſion of Heaven. One of the earlieſt reſtrictions of this practice that occurs in the hiſtory of Europe, is that of Henry I. of England; which was afterwards followed by an edict of Louis VII. of France to the ſame effect. Robertſon's Hiſt. of Charles V. vol. i. p. 61, &c. and 350, &c. 8vo.

Combat is alſo uſed for the ſolemn games of the ancient Greeks and Romans, performed in honour of their gods; as the Olympic games, Pythian, Iſthmian, and Nemæan games; the ludi Actiaci, Circenſes, &c. which ſee in their places, Olympic, Isthmian, &c.

The combats here celebrated, were *running*, *wreſtling*, *boxing*, *ceſtus*, &c. The combatants, who were called *athletæ*, prepared themſelves for it from their youth, by conſtant exerciſe, and a very rigid regimen: they only eat certain things, and at certain hours; drank no wine; had no commerce with women; and both their labour and their reſt were regulated.

COMBATANT, in *Heraldry*, termed by the French heralds *confronté*, when two animals are borne in coat armour in a fighting poſture, erect on their hind feet, and facing each other.

COMBATTANT, in *Ornithology*, the name given by French writers to the Linnæan *tringa pugnax*, the bird known in this country by the name of *Ruffs* and *Reeves*, the male being called the Ruff, the female Reeve. See Tringa *pugnax*.

COMBEAUFONTAINE, a ſmall town of France, in the department of Upper Saone, chief place of a canton, in the diſtrict of Veſoul. It contains 588 and the canton 7596 inhabitants. The territory includes 190 kiliometres and 17 communes.

COMBEFIS, Francis, in *Biography*, a learned French monk, was born at Guienne, in the year 1605. He purſued his ſtudies firſt under the jeſuits at Bourdeaux and afterwards at Paris. He devoted himſelf principally to the purſuit of Greek literature, and was employed in editing new editions of the Greek fathers, for which he received a very handſome remuneration. He likewiſe publiſhed a collection of the lives of different fathers, popes, and martyrs; ſome additions to the "Bibliotheca Græcorum Patrum," in Greek and Latin, in three volumes folio; "Hiſtoriæ Byzantinæ Scriptores, poſt Theophanem," undertaken by command of the celebrated Colbert. He died in 1679 of the ſtone, a diſeaſe to which ſtudious and ſedentary men are peculiarly liable. Nouv. Dict. Hiſt.

COMBANY, in *Geography*, a river of South Wales, in Carmarthenſhire, which diſcharges itſelf into the Loughor, 5 miles N.E. of Llanalthy.

COMBER, Thomas, in *Biography*, was born at Weſterham in Kent, in the year 1645, where he received the rudiments of a learned education; from thence he was admitted in Sydney college Cambridge. He was remarkable for diligence in his ſtudies, and took his degrees of bachelor of arts in 1662, and of maſter of arts in 1666. Some years afterwards he was created doctor of divinity, probably by a diploma from Lambeth. After this he attained to conſiderable rank in the church, and was preferred to the precentorſhip of York, the deanery of Durham, to be chaplain to their majeſties, and other poſts of emolument and honour. Dr. Comber maintained a correſpondence with Tillotſon, Burnet, and other moſt eminent divines of the age in which he flouriſhed. The excellence of his character, and his zeal for the church of which he was a member, were the cauſes that led him to that diſtinction to which he attained, and which was a ſure earneſt and pledge of ſtill greater preferment if he had lived, but he died in November 1699, in the 55th year of his age, and was buried at Stonegrave in Yorkſhire, of which he was rector. He was author of many learned works relating principally to the Common Prayer, and to the offices of the Church of England.

There was alſo another Dr. Thomas Comber, born in Suſſex, Jan. 1575, who was educated in Trinity college Cambridge, and afterwards made dean of Carliſle. In 1642 he was impriſoned, plundered, and deprived of all his preferments, and died at Cambridge in 1653. He is known as the author of "An Hiſtorical Vindication of the Divine Right of Tythes," 4to. written in anſwer to "Selden's Hiſtory of Tythes." Biog. Brit.

Comber, in *Ichthyology*, a ſpecies of wraſſe or old-wife fiſh, found ſometimes on the coaſt of Cornwall, and which is deſcribed under this name in Ray's Synopſis, No. 163. See Labrus *Comber*.

COMBER-MERE, in *Geography*, a lake of England in the county of Cheſter, on the borders of Shropſhire; five miles S. of Nantwich.

COMBINATION, is properly underſtood of an aſſemblage of ſeveral things by two and two; but is more particularly uſed in *Mathematics*, to denote the variation, or alternation of any number of quantities, letters, ſounds, or the like, in all the different manners poſſible.

P. Merſenne gives us the combination of all the notes and ſounds in muſic, as far as ſixty-four; the ſum whereof amounts to ninety figures, or places.

The number of poſſible combinations of the twenty-four letters of the alphabet, taken firſt two by two, then three by three, &c. according to Mr. Preſtet's calculation, amounts to 1391724288887252999425128493402200.

The words in the following verſe may be combined a thouſand and twenty-two ſeveral ways.

Tot tibi ſunt dotes, virgo, quot ſidera cælo.

F. Truchet, in the Memoirs of the French Academy, ſhews, that two ſquare pieces, each divided diagonally into two colours, may be arranged and combined ſixty-four different ways, ſo as to form ſo many different kinds of chequer-work, which appears ſurpriſing enough, when one conſiders that two letters, or figures, can only be combined twice. This note may be of uſe to maſons, paviours, &c. See Pavement, and Changes.

Combination, *doctrine of.—Any number of quantities being given, together with the number in each* combination; *to find the number of* combinations.

One quantity, we obſerve, admits of no combination; two, *a* and *b*, of one, viz. *ab*; of three, *a*, *b*, *c*, there are three combinations, viz. *ab*, *ac*, *bc*; of four, ſix, *ab*, *ac*, *bc*, *ad*, *bd*, *cd*; of five, ten, *ab*, *ac*, *bc*, *ad*, *bd*, *cd*, *ae*, *be*, *ce*, *cc*, *de*.

Whence it appears, that the number of combinations proceed as, 1, 3, 6, 10, &c. which are triangular numbers, whoſe ſide differs by unity from the number of given quantities, or which are produced by the continual addition of the ordinal ſeries, 0, 1, 2, 3, 4, 5, &c. Hence if the number of things to be combined be q, the ſide of the number of combinations will be $q-1$; and therefore the number of combinations $\frac{q-1}{1}\times\frac{q-0}{2}$. See Triangular *number*.

If three quantities are to be combined, and the number in each combination be three, there will be only one combination, *abc*, if a fourth be added, the combinations will be found *abc*, *abd*, *bcd*, *acd*; if a fifth, ten, *abc*, *abd*, *bcd*, *acd*, *abe*, *bde*, *bce*, *ace*, *ade*, *cde*; if a ſixth, twenty, &c. The numbers of combinations, therefore, proceed, as 1, 4, 10, 20; i. e. they are the firſt pyramidal triangular numbers, whoſe ſides differ by two units from the number of given quantities. See Pyramidal *number*.

Hence, if the number of given quantities be q, the ſide will be $q-2$; and therefore, the number of combinations $\frac{q-2}{1}\times\frac{q-1}{2}\times\frac{q-0}{3}$.

Hence is eaſily deduced a general rule for determining the number of combinations in any caſe; for, ſuppoſe the number of quantities to be combined, q, the exponent of the combination n, the number of combinations will be $\frac{q-n+1}{1}\times\frac{q-n+2}{2}\times\frac{q-n+3}{3}\times\frac{q-n+4}{4}\times\frac{q-n+5}{5}$ &c. till the number to be added be equal to n.

Suppoſe, v. gr. the number of quantities to be combined $=6$; the exponent of the combination 4; the number of combinations will be $\frac{6-4+1}{1}\times\frac{6-4+2}{2}\times\frac{6-4+3}{3}\times\frac{6-4+4}{4}=\frac{6-3}{1}\times\frac{6-2}{2}\times\frac{6-1}{2}\times\frac{6-0}{4}=\frac{3}{1}\times\frac{4}{2}\times\frac{5}{3}\times\frac{6}{4}=15$.

Coroll. If it be deſired to have all the poſſible combinations of the given quantities beginning with the combinations of the ſeveral two's, proceeding to three's, &c. there muſt be added $\frac{q-1}{1}\times\frac{q-0}{2}$, $\frac{q-2}{1}\times\frac{q-1}{2}\times\frac{q-0}{3}$, $\frac{q-3}{4}\times\frac{q-2}{2}\times\frac{q-1}{3}\times\frac{q-0}{4}$, &c.

Whence the number of combinations poſſible will be $\frac{q}{1}\times\frac{q-1}{2}+\frac{q}{1}\times\frac{q-1}{2}\times\frac{q-2}{3}+\frac{q}{1}\times\frac{q-1}{2}\times\frac{q-2}{3}\times\frac{q-3}{4}+\frac{q}{1}\times\frac{q-1}{2}\times\frac{q-2}{3}\times\frac{q-3}{4}\times\frac{q-4}{5}$, &c. which is the ſum of the unciæ of the binomial, raiſed to the power q, and abridged of the exponent of the power increaſed by unity, $q+1$. Wherefore, if $1+1=2$ repreſent the binomial to which theſe unciæ belong, 2^q-q-1 is the number of all the poſſible combinations. V. gr. If the number of quantities be 5, the number of poſſible combinations will be $2^5-6=32-6=26$.

2. *Any number of quantities being given, to find the number of changes and alterations, which thoſe quantities, combined in all the manners poſſible, can undergo.*

Suppoſe two quantities, a and b, their variations will be 2; conſequently, as each of thoſe may be combined, even with itſelf, to theſe there muſt be added two variations. The whole number, therefore, will be $2 + 2 = 4$. If there were three quantities, and the exponent of the variations were 2, the combination will be 3, and the changes 3; to which if the three combinations of each quantity with itſelf aa, bb, cc, be added, we ſhall have the number of changes, $3 + 3 + 3 = 9$.

In like manner it is evident, if the given quantities were 4, and the exponent 2, the number of changes would be 16; if 5, 25, &c. in general, if n, n^2.

Suppoſe the quantities 3, and the exponent of variation 3; the number of changes is found $27 = 3^3$; viz. aaa, aab, aba, baa, abb, aac, aca, caa, abc, bac, bca, acb, cab, cba, acc, cac, cca, bba, bab, bbb, bbc, cbb, bcb, bcc, cbc, ccb, ccc.

After the ſame manner, it will appear, if the quantities were 4, and the exponent 3; the number of changes would be $64 = 4^3$; and, in general, if the number of quantities be $= n$, and the exponent 3, the number of changes will be n^3. By thus proceeding, it will be found that if the number of quantities be n, and the exponent n, the number of changes will be n^n; wherefore, if all the antecedents be added, where the exponent is leſs, the number of poſſible changes will be found $n^n + n^{n-1} + n^{n-3} + n^{n-4} + n^{n-5} + n^{n-6}$, &c. Till at length, the number ſubtracted from n leaves 1; becauſe the beginning is from ſingle quantities taken once.

Since then the number of poſſible changes is in a geometrical progreſſion, whoſe firſt or ſmalleſt term is n^1, the greateſt n^n, and the ratio n; it will be $= \frac{n^{n+1} - n}{n - 1}$. Suppoſe, v. gr. $n = 4$, the number of poſſible changes $\frac{4^5 - 4}{4 - 1} = \frac{1020}{3} = 340$. Suppoſe, again, $n = 24$, the number of poſſible changes will be $\frac{24^{25} - 24}{24 - 1} =$ $32009658644406818986777955348272600 \div 23 =$ $1391724288887252999425128493402200$. In ſo many various manners, therefore, may the twenty-four letters of the alphabet be varied and combined among themſelves.

Combination, in *Chemiſtry*, denotes the union of two bodies of different natures, from which a new compound body reſults. An acid united with an alkali furniſhes an inſtance of combination. See Affinity.

Combinations, in *Law*. Combinations to do unlawful acts, are puniſhable before the unlawful acts are executed; this is to prevent the conſequences of combination and conſpiracies, &c. 9 Rep. 57.

Combination, in *Military Science*. One ought to regard combination as forming a part of military ſcience. A general, who has an enterprize in contemplation, ſhould, before he riſks the execution of it, combine well in his mind all the ideas, that can lead to its ſucceſs; and he ought not always to rely on his own ſolution of the caſe. But when his ideas on the ſubject are pretty well fixed, he ſhould lay them before the general officers, who are under his orders or command, for their opinion and concurrence.

COMBINATORY *diſtillation*. See Distillation.

Combinatory *muſic*, *Muſica combinatoria*, that part of muſic which teaches the manner of combining ſounds variouſly; that is, of changing their place and figure in different manners. See Music.

COMBING *of wool*, in *Commerce*, the drawing of wool acroſs the teeth of a kind of card, calculated to diſpoſe it for ſpinning. See Carding and Scribbling.

COMBLEAN. Cordage, which ſerves for charging and diſcharging the pieces of artillery, for mounting them on their carriages, and for raiſing other great weights by means of a crane

COMBLEMENT des Fossés, the filling of the ditches. When the beſiegers have advanced ſo far as to be maſters of the covert-way, they exert themſelves by every poſſible means to fill up the ditches by eſtabliſhing in them galleries to put their workmen under cover, in order to be able to conduct the miner with ſecurity to his operations, and to retrench themſelves there at the ſame time, to ſecure themſelves againſt the ſallies and inſults of the beſieged.

COMBLES, in *Geography*, a town of France, in the department of the Somme, chief place of a canton, in the diſtrict of Péronne. It contains 1579, and the canton 12,196 inhabitants. The territorial extent is of 155 kilometres, and it includes 23 communes.

COMBOURG, a ſmall town of France, in the department of Ille and Vilaine, chief place of a canton, in the diſtrict of St. Malo, 18 miles S. of St. Malo. The place contains 4170, and the canton 12,151 inhabitants; the territory includes 217½ kiliometres and 10 communes.

COMBRAILLE, formerly a ſubdiviſion of the biſhopric of Limoges, in France, now a department of Creuſe. It was a barony belonging to the ducal houſe of Orleans.

COMBREA, in *Ancient Geography*, a town of Greece, ſituated to the north of Pallene, on the Thermaic gulf. Herodotus calls the country in which it lay *Croſſæa*, between Lipaxos and Liſæ.

COMBRE'E, in *Geography*, a town of France, in the department of the Mayne and Loire, and chief place of a canton in the diſtrict of Segré; 7 miles W. of Segré.

COMBRET, a town of France, in the department of the Aveiron; 8 leagues E. of Alby.

COMBRETUM, in *Botany*, (the name of a plant in Pliny.) Linn. Gen. 475. Schreb. 641. Gært. 212. Juſſ. 320. (Chigomier, Lam. Encyc.) Claſs and order, *octandria monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, one-leafed, bell-ſhaped, four or five-toothed, caducous. *Cor.* Petals four or five, egg-ſhaped, about the length of the calyx, and placed between its teeth. *Stam.* Filaments eight or ten, generally very long, inſerted into the calyx; anthers egg-ſhaped or oblong. *Piſt.* Germ inferior, linear; ſtyle briſtle-ſhaped, about the length of the ſtamens; ſtigma acute. *Peric.* none. *Seed* ſingle, with four or five thin membranous wings. (*Capſule* with four or five wings. *Seed* linear, ſmall, with four or five angles, Lam.)

Eſſ. Ch. Calyx four or five-toothed, bell-ſhaped, ſuperior, corolla four or five-petalled, inſerted into the calyx. Stamens generally very long. Seed ſingle, with four or five membranous angles.

Sp. 1. C. *laxum*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Jacq. Amer. 104. Gært. tab. 136? Aubl. Guian. i. 350. tab. 137? Lam. Illuſt. tab. 282. fig. 1? Læfl. It. 308. Swartz. Obſ. 143. (Guara fruticoſa, Læfl. It. 248?) "Flowers octandrous; ſpikes lax, quite ſimple." Lam. "Leaves oppoſite; racemes lax, without bractes; calyxes villous within." Willd. A ſhrub. *Branches* cylindrical, climbing, younger ones brachiate. *Leaves* three inches long or more, petioled, acuminate, ſometimes obtuſe, entire, ſmooth. *Flowers* yellowiſh or whitiſh; in ſimple, axillary, and terminal ſpikes, or rather racemes; ſtamens more than an inch long. A native of Guiana and the Weſt Indies. 2. C. *ſecundum.* Linn. Sp. Pl. 2. Mart. 2. Lam 2. Willd. 2. Jacq. Amer. 103. tab. 176. fig. 30. Swartz. Obſ. 144. "Flowers octandrous; ſpikes compound, panicle-pinnated." Lam. "Leaves oppoſite; racemes unilateral, without bractes; calyces ſmooth." Willd. A ſhrub, or ſmall tree, ten or twelve feet high. *Branches* cylindrical, very long, ſupporting themſelves by the neighbouring trees and ſhrubs. *Leaves* three or four inches long, on ſhort petioles, ovate-oblong, acuminate, entire, ſmooth, veined underneath. *Flowers* very numerous, whitiſh or yellowiſh, in ſeveral ſpikes or racemes, which form a kind of panicle at the ſummit of the branches; anthers red. The flowers, and not the racemes, are often unilateral. Lam. A native of South America, in Guiana, and about the neighbourhood of Carthagena. The ſynonyms of theſe two ſpecies are very confuſed and uncertain. Jacquin ſuppoſes Aublets and Leofling's plants to be the ſame, and to conſtitute a third ſpecies. 3. C. *purpureum.* Mart. 3. Willd. 3. Vahl. Symb. iii. 51. (C. coccineum, Lam 3. Ill. tab. 283. fig. 2. Criſtaria coccinea, Sonnerat. It. ii. 247. tab. 140.) "Flowers decandrous; ſpikes lax, panicled." Lam. "Leaves oppoſite, egg-ſhaped, acute; racemes unilateral, bracteate; bractes ſhorter than the peduncle; flowers decandrous." Willd. A very ſmooth ſurmentous ſhrub, with cylindrical brachiate branches. *Leaves* three inches long, petioled, quite entire, ſomewhat coriaceous. *Flowers* bright red, in terminal panicled racemes; bracte ſolitary, at the baſe of each pedicel briſtle-ſhaped. A native of the iſland of Madagaſcar. 4. C. *decandrum.* Willd. 4. Roxb. Coroman. i. 45. tab. 59. "Leaves oppoſite, oblong, acuminate; racemes lax, bractes longer than the flower; flowers decandrous, in two rows." *Flowers* white, in panicled racemes; bractes lanceolate; ſtamens alternately ſhorter, a little longer than the corolla. A native of woody mountains in the Eaſt Indies. 5. C. *alternifolium.* Willd. 5. Jacq. Amer. 104. Pict. 53. tab. 260. fig. 27. (C. decandrum, Mart. 4.) "Leaves alternate; flowers decandrous." A weak climbing ſhrub, twenty feet high; older branches prickly. *Leaves* two or three inches long, oval-oblong, ending in a blunt, channelled, cartilaginous, quite entire, ſhining, petioled. *Spikes* lax, half a foot long, about ten on one common peduncle, near the end of the little branches, which are often continued weak and leafleſs, ſix feet beyond the flowers. *Flowers* ſmall, uſually coming out before the leaves on very ſhort pedicels. A native of South America, about Carthagena.

COMBRONDES, in *Geography*, a town of France, in the department of Puy de Dôme, chief place of a canton, in the diſtrict of Riom, containing 1568 inhabitants. The territorial extent is of 125 kiliometres, with a population of 7580 individuals diſtributed in 12 communes.

COMBS *of Bees.* See HONEY-*comb.*

COMBURENDO HÆRETICO. See HÆRETICO.

COMBUST, in *Aſtronomy.* When a planet is in conjunction with the ſun, or not diſtant from it above half their diſk; it is ſaid to be combuſt, or in combuſtion.

According to Argol, a planet is combuſt or in combuſtion, when not above eight degrees and thirty minutes diſtant from the ſun, either before or after him.

COMBUSTA, in *Ancient Geography*, a town of Gallia Narbonnenſis, marked in the Itinerary of Antonine, on the route that leads from Narbonne to the paſſage of the Pyrenées.

COMBUSTIO *pecuniæ*, the ancient way of trying mixed and corrupt money, by melting it down, upon payments into the Exchequer. In the time of king Henry II. a conſtitution was made, called the trial by combuſtion; the practice of which differed little or nothing from the preſent method of aſſaying ſilver. But whether this examination of money by combuſtion was to reduce an equation of money only of ſterling, *viz.* a due proportion of alloy with copper, or to reduce it to pure fine ſilver, does not appear. On making the conſtitution of trial it was conſidered that though the money did anſwer *numero et pondere*, it might be deficient in value; becauſe mixed with copper or braſs, &c. Vide Lowndes's Eſſay upon Coin, p. 5.

COMBUSTION, a fire, a burning, denotes the decompoſition of certain ſubſtances, which are thereby called combuſtibles; accompanied with heat and light. The proceſs of combuſtion, the various phenomena it exhibits, its aſtoniſhing effects, its infinite uſes, and its devaſtations, have at all times, rendered it the principal object of human attention in all the various ſtages of life. The whole extent of civil economy, the preparation of food, as well as of almoſt all the articles of neceſſity and of luxury, moſt of the arts of more eſſential uſe to mankind, ſuch as the manufactures of metals, of glaſs, of pharmacy, &c. depend almoſt entirely upon combuſtion. The inclemencies of the weather, and the diſmal darkneſs of night, are removed by means of combuſtion. The moſt active inſtruments of deſtruction depend upon combuſtion. The greateſt ſcenes of wonder, admiration, and terror, like the conflagration of towns, and the eruptions of volcanos, are thoſe in which combuſtion is the ſole actor.

Whilſt the wants and the economy of the multitude, have at all times called forth their induſtry in deviſing eaſy methods of lighting and warming their apartments, of cooking their victuals, &c.; the calm contemplations of philoſophers have endeavoured to inveſtigate the cauſe or cauſes, the commencement, the progreſs, the various intenſity, and the products of combuſtion. It is natural to ſuppoſe that their firſt ideas muſt have been extremely fanciful and incoherent; ſince the preſent theory, which reſts upon the foundation of innumerable experiments and ſtrict reaſoning, is vaſtly different from any ſort of hypotheſis, which even the wiſeſt philoſopher would have been led to form, without the light of thoſe experiments.

The firſt plauſible theory of combuſtion was formed by Stahl, an eminent chemiſt. The ſtriking difference between bodies combuſtible and incombuſtible; that is, between bodies that are, and thoſe that are not ſuſceptible of combuſtion; induced him to ſuppoſe that the combuſtibles were endowed with a peculiar principal of inflammability, which the incombuſtibles had not, and to this ſuppoſed principle he gave the name of *phlogiſton.* According to this ſuppoſition, when combuſtibles were heated to a certain degree, they began to part with this phlogiſton, and continued to burn as long as they had phlogiſton to loſe; after which, they remained in a ſtate of incombuſtibility; hence, in the former ſtate, thoſe bodies were ſaid to be phlogiſticated, and in the latter they were ſaid to be dephlogiſticated. With certain bodies the combuſtion was attended with a ſeparation of other components, ſo that afterwards they could not be brought back to their former ſtate by the mere addition of phlogiſton; but with other bodies, as for inſtance, with the metals, the proceſſes of dephlogiſtication and phlogiſtication might be repeated without end. Thus, a piece of zinc in the metallic ſtate was ſuppoſed to be loaded with phlogiſton, therefore, when expoſed to a ſufficient degree of heat, it would burn, *viz.* it would part with its phlogiſton, and would thereby be reduced into the ſtate of a calx, deſtitute of phlogiſton, and of the metallic appearance; but by placing this calx in contact with bodies which contained abundance of phlogiſton, in a proper ſituation, the calx would thereby be enabled to recover its phlogiſton, and with it its metallic ſtate and combuſtibility. It might then be burnt again, and ſo forth. This plauſible theory was no ſooner made known, than it was eagerly adopted by philoſophers and chemiſts; ſo that for a long period it remained the moſt prevailing theory of combuſtion. But though the theory was univerſally adopted, the exiſtence of the principle upon which it was eſtabliſhed could not be proved. There was no exhibiting the phlogiſtion by itſelf; and it was merely a ſuppoſition that a body acquired or loſt its inflammability, according as it was combined with, or deprived of, its phlogiſton. A ſuppoſition which, on a cloſer examination of facts, was found inadequate to the explanation of the comcomitant phenomena. For inſtance, when a piece of zinc (and ſuch was alſo the caſe with other combuſtibles as far as they might be ſubjected to experiments) of a determinate weight, was burnt and reduced to a calx, the weight of the calx was found to exceed the original weight of the zinc. It was, therefore, evident that it had acquired ſomething ponderable, and this was utterly repugnant to the phlogiſtic theory, for by the loſs of phlogiſton it ought rather to have loſt part of its original weight. In anſwer to this, a ſtrange idea was ſuggeſted, namely, that the phlogiſton was a principle of lightneſs; ſo that bodies became lighter by the addition of phlogiſton and *vice verſâ*. But this ſuppoſition, ſo ſingular and ſo repugnant to the general laws of gravitation, was ſoon abandoned by philoſophers when a variety of deciſive experiments, the concurrence of recent diſcoveries in other branches of philoſophy, and a ſtrict mode of reaſoning, introduced a new theory of combuſtion, which is both ſupported by accurate experiments, and ſufficient to account for the phenomena. One of the principal labours in the experimental inveſtigation, and the full eſtabliſhment of this new and rational theory, was the unfortunate Lavoiſier, to whoſe genius, and to whoſe perſevering induſtry, the ſcientific world muſt ever think itſelf indebted.

In order to render this theory more eaſily underſtood by the reader, we ſhall prefix the following experiment. Take a glaſs veſſel of a cylindrical ſhape, having a ſtopple capable of excluding the entrance or exit of any air, and let the outſide of this veſſel be graduated, ſo as to divide its capacity into pretty ſmall portions. Put into this veſſel, full of common air, a piece of dry phoſphorus of a determinate weight; cloſe the veſſel tight, and heat gradually that part of it in which the piece of phoſphorus ſtands, by means of the flame of a candle. As ſoon as the phoſphorus has been heated to a certain degree, it takes fire of itſelf, burning with a flame and thick white ſmoke; but it ſoon ceaſes to burn. Suffer the veſſel to cool, and the ſmoke will fall in the form of flakes, if the veſſel and the air contained in it were quite dry, otherwiſe theſe flakes will melt in the moiſture. If, in this experiment, the veſſel be weighed before and after the combuſtion, it will be found preciſely of the ſame weight. When the veſſel is cooled to the actual temperature of the atmoſphere, plunge the aperture of it under water, and in that ſituation remove the ſtopple. You will find that the water riſes in it, which ſhews that a portion of the air has been deſtroyed or abſorbed; in ſhort, it has diſppeared. By meaſuring the height of the water riſen within the veſſel, which is indicated by the graduation on the outſide of it; in general, it will be found that about one quarter of the original quantity of air has diſappeared; and the remaining air will be found unfit for the combuſtion of phoſphorus or of any other combuſtible; and is likewiſe unfit for the reſpiration of animals, ſo that if a bird, a mouſe, or any other animal be confined in it, death will ſoon enſue. If the water which has ruſhed into the veſſel be examined, it will be found to have contracted a ſour taſte indicating that an acid has been generated. If the veſſel, inſtead of being opened in water be inverted and opened in quickſilver, then the flakes which in the preceding experiment were diſſolved by the water, will now remain on the ſurface of the quickſilver. This is the acid of phoſphorus, and if it be carefully gathered and weighed, it will be found together with the remaining phoſphorus (if part of it remains unburned), equal to the weight of the original quantity of phoſphorus together with the weight of the air that has diſappeared. Therefore it is evident that the whole proceſs of combuſtion conſiſts in a decompoſition of the pureſt part of reſpirable or atmoſpherical air; the pure part of it, which is about a quarter of the whole, is decompoſed, its baſe is abſorbed by the combuſtible, and generally communicates to it acid properties, in conſequence of which that portion of the atmoſpherical fluid has been called oxygen gas, from the Greek; meaning the acidifying principle. Therefore, in combuſtion, the decompoſition of the oxygen gas is effected by the burning body, when this body has been heated to a certain degree, which degree varies with the nature of the body. The baſe of the oxygen gas is abſorbed and fixed by the burning body, which has thereby its weight increaſed, and its nature changed; whilſt the caloric being diſengaged, paſſes off in the ſtate of ſenſible heat, and ſometimes with ſuch a portion of light as gives the appearance of red or white heat. Acids in general are formed from the abſorption of oxygen during combuſtion. See Oxygen Gas.

When the combuſtion is accompanied with red heat, but not with flame, it is called *ignition*. But ignition may alſo be applied to incombuſtible ſubſtances, for theſe may be rendered red or white hot, without ſuffering any decompoſition. When a vapour ariſing from the heated body burns over it, it is then called *inflammation*; and when the inflammation is rapid and attended with noiſe, it is called *detonation*. Having now compendiouſly ſtated the new theory of combuſtion, it is neceſſary to add ſeveral neceſſary remarks reſpecting every part of it, which could not be intermixed with the theory without rendering it confuſed and leſs intelligible.

In the firſt place, ſince the proceſs of combuſtion conſiſts in a decompoſition of oxygen gas, the generalizing ſpirit of modern philoſophy includes every proceſs, in which oxygen gas is decompoſed, under the general name of combuſtion; thus, animal reſpiration, in which this gas is decompoſed, its baſe abſorbed, and heat evolved; may be reckoned amongſt the proceſſes of ſlow combuſtion. See Respiration. The gradual abſorption of oxygen by metallic bodies may alſo be reckoned amongſt thoſe proceſſes.

Since combuſtion conſiſts in a decompoſition of oxygen gas, it naturally follows that without oxygen no combuſtion can take place. The oxygen, however, may be contained in other ſubſtances, in conſequence of which thoſe ſubſtances become capable of aſſiſting combuſtion. Now there are ſeven of thoſe ſubſtances, which, from their containing oxygen, are called *ſupporters* of combuſtion; and theſe are oxygen gas, atmoſpheric air, nitrous oxyd, nitric oxyd (which is procured by digeſting copper and mercury in diluted nitrous acid, and collecting the gas which is extricated), nitric acid, oxygenized muriatic acid, and hyperoxygenized muriatic acid. See the nature of thoſe ſubſtances under the article Gas. It alſo follows that with a given combuſtible, the quickneſs of the decompoſition is proportionate to the ſupply of oxygen, which ſhews the reaſon why a fire is increaſed by blowing common air, and much more by blowing oxygen gas upon it. But cæteris paribus with different combuſtibles, the fire is ſtrongeſt when the combuſtible has the ſtrongeſt attraction for oxygen. The flame of hydrogen gas urged by oxygen gas is reckoned to produce the moſt intenſe heat.

A combuſtible body, though expoſed to oyxgen, generally requires to be heated to a certain degree before the combuſtion commences. That degree varies with the nature of the body, and the purity of the oxygen; ſo much ſo that ſome of them, though not many, take fire immediately on being expoſed to ſome of the above-mentioned ſupporters of combuſtion in the common temperature of the atmoſphere, whilſt others muſt be heated to a red and even to a white heat, before the decompoſition takes place.

When the combuſtion has once commenced, the heat or caloric, in the form of ſenſible heat, which is extricated from the oxygen gas, raiſes the temperature of the adjacent parts of the combuſtible to that degree which is neceſſary for its combuſtion, and the heat evolved by the burning of this part heats the next and ſo on. But this is not the caſe with all ſorts of combuſtibles; for ſome there are which muſt be kept up at a given high temperature in order to effect their combuſtion, and a diamond is of this ſort. However the nature of combuſtibles in this reſpect varies according to the purity and quantity of oxygen. For inſtance, if a ſlender ſteel wire be expoſed to the flame of a candle in common air, that part of it only will burn, which is acted upon immediately by the flame; but if the ſame wire be lighted by means of a bit of tinder, and then be plunged in a veſſel full of oxygen gas, it will burn ſucceſſively to the very end, like a ſlip of paper; exhibiting a remarkable bright light, and very conſiderable heat.

Of the ſimple bodies of nature, the chemiſts reckon three combuſtible ones, and two that are incombuſtible. The former are ſulphur, phoſphorus, and hydrogen; and the latter are azote and muriatic acid; but amongſt the compound bodies, the combuſtibles are much more numerous. Such are oils, acids, and a vaſt variety of others which being of a fluctuating nature need not be particularly ſpecified.

A variety of experiments, which may be found under the article Gas, prove that gaſſes owe their elaſtic nature to a conſiderable quantity of caloric, which muſt neceſſarily combine with their baſe, in order to aſſume the aerial form. Therefore, when, in conſequence of the ſuperior affinity of the combuſtible for oxygen, the oxygen gas is decompoſed, and its baſe condenſed, the caloric, which was neceſſary to its aerial form, being ſet at liberty, appears in the form of ſenſible heat; hence the heat which accompanies combuſtion is naturally ſuppoſed to proceed from the oxygen gas; and the quantity of it varies according to the rapidity of the proceſs, ſo much ſo that in certain proceſſes like the decompoſition of oxygen effected by metallic ſubſtances in common air, it is not attended with any ſenſible degree of heat; for the heat evolved, being very ſlight, is inſtantly diſſipated among the ſurrounding bodies.

With certain combuſtible bodies a peculiar proceſs takes place. It is a remarkable ſlow proceſs of ſpontaneous combuſtion. The body, by attracting oxygen from the atmoſphere, becomes thereby gently heated, in conſequence of which its affinity to oxygen is increaſed, a greater decompoſition of the latter enſues, more heat is evolved, and thus the proceſs is gradually accelerated until flame and viſible combuſtion take place. Such is ſometimes the caſe with hay, the ſaw-duſt of certain woods, and various other ſubſtances. The well known mixture of iron filings and ſulphur moiſtened with a little water, is an inſtance of this ſort; for if this mixture be buried a little below the ſurface of the ground, it will of itſelf, after the lapſe of ſeveral hours, burſt forth in a ſtate of ignition. This experiment has been generally called the *artificial volcano*.

Though heat in combuſtion is derived from the oxygen gas, the derivation of light is not ſo evident. It has been for a long time ſuppoſed that this element alſo was one of the components of oxygen gas; but the obſervations made reſpecting the light yielded by ſeveral bodies when they are ſlightly heated, or even ſpontaneouſly, and that ſome of them yield much more light than others, ſeem to prove, that light forms a component principle of moſt bodies, and that it is evolved from the combuſtible. It is likely, however, that part of it may be derived from the oxygen alſo.

The following liſt of bodies ſubject to ſpontaneous inflammation is given by profeſſor Bartholdi; meaning the inflammation occaſioned by different bodies acting upon each other, without the aid of another body previouſly in a ſtate of combuſtion.

1. Friction. Thus pieces of wood rubbed againſt each other are thereby inflamed. The beſt for this purpoſe are box-wood rubbed againſt mulberry, or laurel againſt poplar, or againſt ivy, &c. It is in conſequence of friction that the wheels and axletrees of carriages ſometimes take fire, when they are not ſufficiently greaſed. In turning alſo, pieces of wood ſometimes take fire.

2. The action of the ſun's rays concentrated by lenſes, or concave reflectors, or even by plane reflectors, provided their reflections be thrown upon the ſame ſpot. See Burning-*Glaſs*, and Reflectors.

3. The ſudden ſlacking of quicklime has ſometimes been known to produce the combuſtion of adjacent bodies.

4. The fermentation of animal and vegetable ſubſtances. Thus great accumulations of hay, turf, or flax, and hemp, heaps of linen rags in paper mills, &c. take fire, provided they are not quite dry; for without moiſture, fermentation and the conſequent evolution of heat cannot take place.

5. The accumulation of animal and vegetable ſubſtances covered with an oil, eſpecially when the oil is of a drying quality. Thus lamp-black mixed with linſeed oil is apt to take fire, and an earth of a brown colour, called the *black wad of Derbyſhire*, ſprinkled over with a little linſeed oil, takes fire and appears red-hot like burning ſmall coal, in about an hour's time.

6. There are ſeveral ſubſtances, which have the property of inflaming ſpontaneouſly, increaſed by torrefaction. Coffee, French beans, lentils, &c. are of this nature.

7. Sulphurated and phoſphorated hydrogen gas. The cauſe of ſubterraneous fires and volcanoes in general, is attributed to the decompoſition of pyrites, or metallic ſulphurets, buried in the interior of the earth. Theſe pyritous maſſes are decompoſed by the contact and concurrence of water and air, and the decompoſition is always accompanied with a great extrication of caloric, and a diſengagement of a very inflammable gas, called *ſulphurated hydrogen gas*. This gas inflames at an elevated temperature, and communicates the inflammation to the ſulphur of the pyrites, to the coal and other bituminous matters, which generally accompany it.

8. Sulphuret and phoſphuret of lime and of potaſh, formed in the combuſtion of ſeveral vegetables.

9. Phoſphorus ſometimes contained in charcoal.

The laſt particulars which we need take notice of, concerning the theory of combuſtion, are its products. But theſe muſt not be miſtaken for thoſe bodies which exiſted in certain combuſtibles, and have been left by themſelves when the other components of the combuſtible have been ſeparated, ſuch as earthy particles, &c. The real products of combuſtion are thoſe which did not exiſt before, and theſe, upon a ſtrict examination, will be found to be either water, or an oxyde, or an acid. Water conſiſts of oxygen and hydrogen. See Water. An oxyde is a compound of the combuſtible with oxygen, but not ſuch as to poſſeſs decided acid properties, (and the proceſs is called *oxydation*), or an acid, which conſiſts of the acidifiable part of the combuſtible, combined with oxygen ſufficiently to give it decided acid properties. Thus, the combination of carbon and oxygen forms the carbonic acid gas, and this is produced in almoſt every combuſtion, alſo in reſpiration, &c.

COMCHE, in *Geography*, a town of Perſia, where the caravans reſt in their way from Iſpahan to Ormus.

COME, in *Biography*. See Cosme.

Come. The ſmall fibres or tails of malt, upon its firſt ſhooting forth, are thus called.

COME-IN. Soldiers are ſaid to come in as recruits, volunteers, &c. when they come to join any particular corps or ſtandard.

COME-OVER. When men deſert from one army and join another oppoſed to it, they are ſaid to come over to the one, which they join or go over to.

To come *in to*, to join, to bring aid or aſſiſtance.

To come *up with*, to overtake. *To come up with an enemy*, is a military phraſe much made uſe of.

Come *ſopra*, in the *Italian Muſic*, literally ſignifies *as above*, and is uſed when any foregoing part is to be repeated.

COMEA, in *Ancient Geography*, a place of European Myſia, which was an epiſcopal ſee, called by the council of Nice *Comeenſis*.

COMEDÆ, a people of Scythia, compriſed by Ptolemy under the general name of Sacæ.

COMEDONES, a name given to a ſpecies of worm, with which the children of Miſnia, and ſome other countries, are terribly afflicted; and of which Hoffman, in his "Treatiſe of Endemial Diſeaſes," gives this account; children in the country are frequently ſeized with a ſort of tabes, which ſo deſtroys their fleſh, that they appear merely like ſhadows. The common people generally ſuppoſe theſe children to be under the influence of witchcraft; but ſuch as have inquired more narrowly into the diſtemper, have found that it is owing to certain worms, reſembling black hairs or cords, lodged under the ſkin. When the ſkin is rubbed with honey, in a bath, or any warm place, they will appear and come out; but when it is contracted by cold, they keep concealed within. See Affectio *bovina*, and Dracunculi.

COMEDY, in its proper ſenſe, ſignifies an allegorical repreſentation of ſome characteriſtic tranſaction in private life. The drama, under its various forms, has in all ages and countries been cultivated, not only as a rational and polite amuſement, but as a ſerious art, affecting the moral conduct of men, and influencing the condition of ſociety. According to the field it occupies, whether the lighter traits of incidental character, or the important events of life, it aſſumes the form of tragedy or comedy. The firſt commands awe; the laſt excites more pleaſureable and exhilarating ſenſations. The firſt exhibits the fall of a hero; the laſt conducts the fortunes of lovers to the goal of marriage, and ſets down the eccentricities of every character it meets with on the way. If therefore tragedy is more exalted, comedy comes cloſer to the heart, and appeals more powerfully to the experience of man. The ſtronger paſſions, the virtues, the crimes, the ſufferings of mankind are the theme of the one: our humours, our follies, the effervеſcence of youth, or the ſeverity of years the topics of the other. Terror and pity are the inſtruments of pleaſure in the firſt caſe, but ridicule in the laſt.

It is therefore very eaſy to diſcriminate the general ſpirit and ſtrain of comedy from that of tragedy. Neither is it leſs moral or leſs uſeful, when conſidered as a ſatirical exhibition of human life, with all its improprieties and abſurdities. There is nothing in the nature of theſe compoſitions, in either kind, which militates againſt good morals; though a French author endeavoured to affix the imputation of a profane and antichriſtian ſpirit on the great Corneille. The improvement of manners, the regulation of ſocial intercourſe, the ſubjection of vicious conduct to the laſh of infamy, are among the benefits reſulting from this ſpecies of poetry. Ridicule often ſucceeds where argument fails. Yet is it a dangerous weapon, when unſkilfully wielded. For it is by no means the teſt of truth. It may be applied to miſlead and ſeduce, inſtead of reforming; and the blended colours of ridicule are ſometimes more difficult to ſeparate, than the ſtrong lights and ſhades of truth and error. Cicero quotes ſome lines of a comedy, where love is repreſented as the greateſt of the deities. On the ſtrength of this ſentiment, he exclaims loudly againſt comic poetry as a corrector of morals; contending at the ſame time, that the art could not exiſt, if it had not vanity or villainy to feed upon. Beſides this, it happens too frequently, that the ridicule falls where it is leaſt deſerved. This however is the fault of the writer, and not to be imputed to the nature of his ſubject. It depends on the combatant, whether the ſword ſhall be drawn in a good cauſe, or in a bad one. The ſucceſs of tragic repreſentations gave riſe to the ancient comedy at Athens. In the latter, as well as in the former, the unity of action and ſubject is abſolutely requiſite, and thoſe of time and place ſhould be as nearly as poſſible preſerved. By this is meant, that the time of action ſhould be reduced to moderate limits, and the place never changed but with the termination of the act. The ſcenes of converſation muſt be united in a natural ſucceſſion, and the ſtage ſhould be perpetually occupied during the continuance of the act. The audience ſhould likewiſe be made to perceive the neceſſity of the various perſonages appearing and diſappearing juſt as they do. By theſe means, the imitation is allied to probability, and pleaſes in proportion. Probability is indeed more indiſpenſibly neceſſary in comedy, which deſcends to ordinary life, than in tragedy. Nature, whether in the management of the incidents, or the delineation of character and ſentiment, is the only ſolid foundation for this ſpecies of writing. The ſcene and ſubject of comedy ſhould be laid in the country and time, where and when it is to be repreſented. The little proprieties or indecorums of character and behaviour vary with the moment, and become uninteresting or unintelligible, except where they are ſeen and known in real life.

The various perſonages in a well managed comedy ought to be diſtinctly marked, without the affectation of contraſting them by pairs. Ordinary writers may ſeem to acquire a ſtrong light and ſhadow by quaint artifices like theſe: but a maſter looks no further than real life, and repreſents it as it is. The diction ſhould be eaſy, natural, and poliſhed, on a level with the converſation of gentlemen in the higher walks, but above the groſſneſs of the vulgar in the lower. Perhaps there is nothing in the art ſo difficult, as to ſupport a ſpirited and happy dialogue. The parade of miſplaced wit has ſpoiled almoſt as many comedies as actual dulneſs.

The feaſt of Bacchus, Suſarion on his ſtage, and Theſpis in his cart, are the humble origin uſually aſcribed to the drama. Suſarion repreſented his firſt pieces towards the year 580 B. C. Theſpis made his firſt attempts in tragedy, and acted his Alceſtis in 536 B. C. The former attacked the vices and abſurdities of his time; and the latter treated more noble ſubjects, which he took from hiſtory. See DRAMA and THEATRE. Comedy had three ſtages among the Greeks. The ancients indulged in the licence, not only of dramatiſing actual and well-known occurrences, but of identifying them with living perſons. The name even of Socrates was not withheld from theatrical ridicule; and the philoſopher was among the number of the audience. This licence in proceſs of time was interdicted by the authority of the magiſtrates. The players no longer at liberty to ſport with real names, contrived maſks to reſemble the features of thoſe whom they meant to attack: this was the middle comedy. This latter abuſe was ſcarcely leſs offenſive than the former; and was at length prohibited. Deprived of maſks as well as of names, the new comedy confined itſelf within thoſe modeſt and moral bounds, which Menander ſet to its irregularities in the time of Alexander the Great. On this model, Plautus and Terence formed their ſtyle, without taking the trouble of transferring the ſcene to their own country. This ſpecies of entertainment was then ſcarcely naturalized among the Romans; and their performances were rather tranſlations than originals. In the courſe of time, Rome diſtinguiſhed its comedy, founded on native manners, by the name of Comœdia Togata, and that which was borrowed from the Greeks, was diſtinguiſhed as the Comœdia Palliata.

Before the introduction of modern comedy, a ſpecies of dramatic repreſentation was in vogue, taken from the ſtories in the Old and New Teſtament, the Martyrdoms of the Saints, and other religious ſubjects. They were called myſteries: as the myſtery or the Play of the Paſſion, the myſtery of the Acts of the Apoſtles, the myſtery of the Apocalypſe, &c. Theſe entertainments were at firſt given in the churches, and made a part of the eccleſiaſtical ceremonies. Afterwards the myſteries were played on a public ſtage. On the entrance of Charles VII. into Paris in the year 1437, ſcaffolds were erected all along the great ſtreet, St. Deny's, on which were acted, with ſplendid and appropriate decorations, the Annunciation of the Bleſſed Virgin, the Nativity, our Lord's Paſſion, his Reſurrection, the day of Pentecoſt, and the laſt Judgment. In the year 1486, the chapter of the cathedral at Lyons voted ſixty livres to the performers in the myſtery of Jeſus Chriſt's paſſion. About 1540, the ſame city exhibited on Sundays and holidays, for the ſpace of three or four years, the greater part of the hiſtorical facts in the Old and New Teſtament, ſucceeded by a farce, in the ſame manner as in our theatres. The popular name of the play-houſe was Paradiſe. Theſe ſacred comedies were much in faſhion in France under Francis I. who patronized them, and attended their repreſentation. One of thoſe, which attracted his approbation, was entitled the myſtery of the paſſion of our Lord and Saviour Jeſus Chriſt. It is ſaid in the title page to have been performed "triumphantly at Angiers:" and indeed ſo it muſt have been; for there were one hundred and forty-one characters in the dramatis perſonæ. The date of it is 1541. But the abuſes to which theſe religious performances gave riſe occaſioned at length a very ſevere law throughout the kingdom, againſt the exhibition of "Our Lord's Paſſion," and other ſimilar ſubjects. Many of theſe pieces are ſtill extant in print.

One of the firſt objects in modern comedy, is the Spaniſh theatre, fertile as it has been in dramatic productions. Lopez de Vega, Guillin, and Calderon, are the principal comic writers of Spain. The firſt of theſe, and the moſt celebrated, is ſaid to have written above a thouſand plays. [illegible] our ſurpriſe at their number is leſſened when we become acquainted with their nature. Neither the unities, nor any other rules of dramatic writing are in any degree obſerved. One piece often contains the life of a man, nor is the ſcene limited to one quarter of the globe. They are for the moſt part tragi-comedies, taken from Spaniſh hiſtory; where war and heroiſm are coarſely mixed up with ridicule and buffoonery. Allegorical and mythological characters, the Pantheon and the ſacred myſteries, contribute their joint ſtock to theſe extravagant and unique performances. Yet are they not without ſtrong traits of genius, and much ſplendour of imagination. The characters are ſometimes well drawn, and the ſituations happy. To this writer, more than any other, are the public indebted for that taſte for the ſurpriſing, which ſo ſtrongly pervades the modern drama. It is plain from his own apologies, that Lopez de Vega complied with the whimſical fancies of his countrymen; and that had he been at liberty to have led the taſte of his times, inſtead of following it, his ſtories would have been more natural, his intrigues more ſkilfully entangled and unravelled, and his characters more conſiſtently preſerved.

The French comic theatre is in general an excellent ſchool of manners; correct, chaſte, and decent. It may well boaſt of ſuch writers as Regnard, Dufreſny, Dancourt, and Marivaux; but Moliere is the glory of their ſtage. No writer in any department roſe to a higher reputation, in the brilliant age of Louis XIV. It may indeed be queſtioned, whether any comic writer has ever appeared with ſo many excellencies and ſo few defects. Vice and folly are the only objects of his ſatire. Though his characters are often peculiar to his own country and times, the ridicule is applied ſo juſtly as ſcarcely to have loſt its force with foreigners or with poſterity. His mirth is not indulged at the expence of good morals. The "Miſanthrope," and "Tartuffe," are in verſe; they therefore riſe into greater dignity, and aſſume the ſtyle of elegant ſatire. In his proſe comedies he is more ludicrous. His excellence conſiſts more in the ſtrength of his characters, than in the conduct of his plots. He is occaſionally too farcical in his proſe, and too prolix in his verſe. "Tartuffe" in the grave comedy, and his "Avare," in the lighter, are uſually conſidered as his maſter-pieces.

Engliſh comedy abounds more in original characters, than the comedy of any other modern nation. Humour is a leading feature in the character of the people. The freedom of our government and manners affords a wider ſcope to the comic muſe, than ſhe is allowed in the deſpotic courts of the continent. This boldneſs has, however, too often degenerated into a licence almoſt bordering on the immorality of the ancient Greek comedy. But this error has, however, been corrected in later times, and the ſtage has conformed to the more decent manners of an age which is rapidly diſcarding the groſſneſs of vice from public view.

It now only remains to give a character of ſome of our moſt eminent comic writers.

Shakſpeare decidedly takes the lead in each department of the drama; but his excellencies are ſo univerſally felt and underſtood that it would be ſuperfluous to enter into a criticiſm of his productions. Of Jonſon it will only be neceſſary to notice a few leading pieces. "Every Man in his Humour" is a play which places this writer ſcarcely lower than the higheſt, whether we advert to the variety of its characters or the energy of its compoſition. It is to the credit of the preſent taſte, that it regained poſſeſſion of the ſtage, in defiance of its obſolete alluſions, and antiquated garb. "Every Man out of his Humour" has much leſs to recommend it than the preceding comedy, though ſtrongly marked in point of character. It has undergone the uſual fate of perſonal ſatire, to die with the individuals at whom it glances.

"Cynthia's Revels" and the "Poetaſter" are chiefly to be remembered, as having been acted by the children of queen Elizabeth's chapel; a relic of theatrical entertainment after the mode of its ancient inſtitution, when the ſacred myſteries were repreſented by the choir of the church or monaſtery.

Volpone is perhaps the beſt of this author's comedies. The language and character are wrought up to the higheſt finiſh, and the poet exhibits an originality of plot, conception, and execution, which proves that he could throw aſide the trammels of the ſtudent, and lay claim to the honours of an unindebted thinker, as well as thoſe of a ſucceſsful imitator. The pictures of Volpone and Moſca are finely imagined, and their circumſtances moſt happily delineated. His "Epicœne" is exceeded by few comedies in the Engliſh language. If to theſe two we add the "Alchymiſt," the merits of which are univerſally allowed, though the object of its ſatire has given place to other errors and other follies, we ſhall form ſuch a conſtellation of comic genius, as will outſhine all competition but that of his illuſtrious contemporaries. His later pieces, conſiſting of his "Bartholomew Fair," "Staple of News," "New Inn," "Magnetical Lady," and "Tale of a Tub," rather detract from his reputation than augment it; and prove, what many other dramatic writers would have done well to conſider, that faculties devoted to the entertainment of the public will at length be exhauſted, without ſome ſources of repletion from change of ſcene or circumſtances.

The triumvirate, ſuch as was never equalled, before or ſince, in the republic of letters, was completed by John Fletcher, whoſe merits are cloſely blended with thoſe of his aſſociate Beaumont. His genius rather aſſimilates with Shakſpeare than with Jonſon, to whom he is confeſſedly inferior in propriety and preciſion, while he ſurpaſſes him in creative powers and poetical fecundity.

The next writer that obtained a large portion of the public favour and attention was Davenant, whoſe propenſity to poetry is ſaid to have appeared ſufficiently early in life to attract the favourable notice of Shakſpeare, though the great bard died when this young rhymer was only ten years old. What is commonly conſidered as Davenant's firſt play was produced in 1629, though he had attempted dramatic compoſition two or three years before. It is not worth while to enumerate the order or titles of his plays and maſques; which were in general well received, and procured his promotion to the laurel, vacant by the death of Jonſon, as a reward for the aſſiduity with which he directed the diverſions of the court, as long as the troubles of the times permitted it to have any. It was to his addreſs, that the people were indebted for the gradual reſtoration of the muſes, after an interregnum of ſeverity and gloom. At firſt he prevailed on men of taſte and learning to countenance a haſty ſpecies of dramatic melange, which was allowed becauſe it was bad, by the ignorant bigots who held the reins of empire, while rational and regular plays were abſolutely prohibited. But he imperceptibly enlarged his ſphere of compoſition, and after the reſtoration obtained the patent of the theatre in Lincoln's Inn Fields. The ſtage is not perhaps more deeply indebted to any man than to Davenant, for the convenience and aptitude of its arrangements in the manager's department. Beſides many leſs material improvements, it owes to him the introduction of female performers, and painted ſcenery; and from his revival of "Macbeth" and the "Tempeſt" may be dated that devotion to embelliſhment, which has ever ſince inundated the Engliſh ſtage, and, in the judgment of ſeverer critics, overwhelmed the ſenſe and diſcernment of the audience. His irregular entertainments, reſorted to in the firſt inſtance only as ſubſtitutes for better things, may indeed be conſidered as the root of all that theatrical evil, we ſo gravely condemn, but at the ſame time ſo freely encourage. Yet he had the praiſe of bringing forward to the public eye ſcenery, women, and Betterton.

Maſſinger was alſo among the ſterling ſupports of the Engliſh drama; of which he may juſtly be reputed one of the fathers. His ſtyle was rough, manly, and vigorous; he preſſed upon his ſubject with a ſevere but maſterly hand; his wit was cauſtic, and his ſerious dialogue, according to its ſubject, ſtern and impreſſive, or natural, eaſy, and intereſting.

Dryden did not commence his career as a writer for the theatre, till the thirty-ſecond year of his age; but from that period he kept poſſeſſion of it, and produced eight and twenty dramas, not indeed without competition or cenſure, but with a large ſhare of predominant reputation. His firſt production was the "Wild Gallant;" a comedy, which met with ſo indifferent a reception, that had Dryden been a man of fortune, the ſtage had never again been benefited by his aſſiſtance. He was aſſociated with Davenant, in the alteration of the "Tempeſt;" but he acknowledges the invention and writing of the new characters chiefly to belong to his colleague. We cannot, however, help contemplating the perfections of Shakſpeare with aſtoniſhment, when we find that two ſuch powerful minds could produce little or no addition to the effect.

On the character of his comedies, it will not be difficult to decide. He has, himſelf, acknowledged his inaptitude to that ſpecies of compoſition; and certainly his plays in general have much leſs merit than his other writings. Yet, after all, he has eſtabliſhed a reputation that will never fade, even in this branch of poetry; and his drama of the "Spaniſh Friar" may be ſelected, as an inſtance of happy coincidence and real ingenuity, in the combination of ſerious and riſible materials. Indeed the unfitneſs of his comic performances for modern repreſentation ariſes more from their extreme licentiouſneſs and immorality than from any defect of power.

The comedies of Otway are deſervedly excluded from the reading deſk as well as from the ſtage, on account of their undiſguiſed obſcenity.

Congreve, at the age of twenty-one, produced the "Old Bachelor," at the theatre in Drury Lane, to amuſe himſelf in a ſlow recovery from a fit of ſickneſs. It received ſome requiſite touches from the maturer judgment of his friends, and Dryden declared that he had never ſeen ſuch a firſt play. The "Double Dealer," and "Love for Love" ſucceeded it, at an interval of a year each. Five years afterwards his comedy, called the "Way of the World," cloſed his dramatic labours at a time of life, when writers in general are but beginning their career. The indifferent ſucceſs of his maſterpiece excited his diſguſt at the caprices of the public. He never reſumed his pen in the ſervice of the theatre, except to write a maſque, called the "Judgment of Paris," and an opera, called "Semele," which was never repreſented; but as his fame reſts on his five regular pieces, we may conſider him as loſt to the ſtage, after the unkind reception of a play, which has ſince vindicated its ſtation among the moſt brilliant ornaments of the drama.

It is on his comedies principally, that Congreve's reputation ſubſiſts. Here, all is luminous, all genuine, pointed, and original. His men of faſhion are gentlemen, and even his fops are wits. Congreve is conſidered as having leſs humour and leſs of real life, than his illuſtrious rivals of the ſock. But, ſurely "Foreſight" abounds with the richeſt humour, and that of a deſcription, which, though now antiquated, was living and current at the time. Indeed it is an undoubted teſtimony to the happy drawing of this character, that though it is only recognized by the modern ſpectator as a picture of the days that are gone by, it never fails to excite riſibility on the ſtage in a very powerful degree. The leading feature of Congreve's genius is wit. Dr. Johnſon ſays, that he formed a peculiar idea of comic excellence, which he ſuppoſed to conſiſt in gay remarks and unexpected anſwers. Now, certainly, in adopting ſuch a theory of compoſition, he too much narrowed his own ſphere. Still, however, no more is to be required of a writer, than what he himſelf undertakes; and Congreve performed what he undertook with a brilliancy of ſucceſs, which, with the exception of Mr. Sheridan, has neither been rivalled nor approached in the revolution of the century that has elapſed. It has been objected, that "his perſonages are a kind of intellectual gladiators; every ſentence is to ward or ſtrike; the conteſt of ſmartneſs is never intermitted." This remark is undoubtedly true; yet, when we find Congreve thus formidably cenſured for the exuberance of his wit, it is impoſſible not to feel as the king of Pruſſia did, when he wiſhed a certain mad commander to bite ſome of his generals.

Could the licentiouſneſs of Congreve's topics be as eaſily juſtified as the overflowings of his gaiety, his fame would continue to blaze without danger of eclipſe. But in truth, the offence his muſe occaſions to the purer ears of a more moral age, has an unhappy tendency to ſhorten his theatrical exiſtence. The obſervation applies equally, if not in a greater degree, to all his witty, but graceleſs contemporaries; and it may be remarked on ſuch freedoms in general, that they create diſguſt and alienation, at leaſt in ſome minds, in a place and on an occaſion, where it ſhould be as much an author's ſtudy never to offend any, as occaſionally to pleaſe all; conſequently though they may increaſe the number of temporary plaudits, they infect the vitals of a reputation, that otherwiſe might have been immortal, with a principle of early decay.

To particularize the merits either of Congreve's rivals, Wycherly, Farquhar, Vanburgh, &c. or the numerous claſs of writers in the ſucceeding ages, who have cultivated the *comedie larmoyante*, would exceed the limits of this article. The latter is indeed almoſt as obſolete as the coarſe but ſterling wit of king Charles's days. It has given place to the diſtorted portraits and philoſophy-run mad of the German ſchool; a taſte from which it is moſt devoutly to be wiſhed that the drama may be ſpeedily reſcued.

COMENII, in *Ancient Geography*, a people of Illyria, according to Ptolemy, adjoining to the Daurſiani and Vardæani.

COMENITZA, in *Geography*, a town of European Turkey, in the province of Epire, 52 miles S.W. of Delfino.

COMENIUS, John Amos, in *Biography*, a celebrated grammarian and divine, was born in the year 1592, in Moravia. He ſtudied at Herborn, and returned to his own country in 1614, and was appointed rector of a college there. In 1618 he became paſtor of the church at Fulnec, and was appointed maſter of the ſchool which had been lately erected. Here he conceived the idea of an improved method of teaching the languages, but his writings on this ſubject were deſtroyed in 1621, when the town was taken and plundered by the Spaniards. In 1624 he retired from the perſecutions inflicted upon the Proteſtants in Germany, to Leſna, a city of Poland, where he devoted himſelf to the inſtruction of young perſons in the Latin language: here he publiſhed in 1631 his "Janua Linguarum reſerata," a work which obtained for him great reputation, and which was ſpeedily tranſlated into 12 European languages, and alſo into the Arabic, Turkiſh, Perſian and Mogul languages. He was now invited into Sweden to take the charge of the public ſchools in that kingdom, which he declined; and having publiſhed the "Panſophiæ Prodromus," or "Forerunner of Univerſal Science," he was ſolicited by the parliament of England to undertake the reformation of the ſchools there. He arrived in London Sept. 1641, but owing to the civil wars his propoſals were neglected, and he went to Sweden, and from thence to Elbing in Pruſſia, where he employed ſix years in perfecting his new method of inſtruction, but did not meet with ſufficient encouragement to induce him to publiſh his thoughts on the ſubject. In 1648 Comenius was invited to the court of Sigiſmund Ragotſki, prince of Tranſylvania, where he lived four years, and propoſed regulations for the college of Patak, upon the plan of his Panſophia, from whence he returned to Leſna, and continued there till 1656, when the town was burnt in the war between the Swedes and the Poles. On this occaſion he loſt all his manuſcripts excepting what he had compoſed on his Panſophia, and the Apocalypſe. He fled into Sileſia, thence to Brandenburgh, afterwards to Hamburgh, and laſtly to Amſterdam, where he continued till his death, which happened in 1671. At Amſterdam he publiſhed his "New Method of Teaching," which added nothing to his reputation, and which the learned Bayle has declared of no worth whatever in the art of inſtruction. In this opinion he is ſanctioned by the concurrent voice of the learned in every ſucceeding age to the preſent time.

Comenius was not only intent upon the reformation of ſcholaſtic learning, but he embraced the notions of a ſpeedily approaching millennium, and pointed out as characters who were to be eminently diſtinguiſhed in fulfilling the prophecies, Guſtavus Adolphus, Cromwell, and others, who had little claim to the honours of a divine miſſion. Succeeding events contributed to diſſipate, in ſome meaſure, the enthuſiaſtic notions which he had embraced and cheriſhed. By ſome of his contemporaries he was charged with having poſſeſſed more knavery than credulity, but of this there ſeems to be no ſatisfactory evidence. He publiſhed "Commentaries on the Apocalypſe," ſome treatiſes on the Socinian controverſy, and "Hiſtoria Fratrum Bohemorum," in 4to. Nouv. Hiſt. Dict. Bayle.

COMENOLITARI, in *Geography*, a country of modern Greece, which compriſes the ancient kingdom of Macedonia and Theſſalia.

COMENSES, in *Ancient Geography*, a people of Aſia Minor, towards Galatia, according to Pliny. Hardouin calls them Chomenſes, deriving their name from Choma, a town ſituated in the interior of Lycia.

COMERCHIN, in *Geography*, a town of European Turkey, in the province of Romania; 62 miles E. of Emboli.

COMES *Nervi Phrenici*, in *Anatomy*, is a ſmall branch of the internal mammary artery. See Arteries.

Comes, in *Antiquity*. See Count.

Comes, Natalis, in *Biography*, was born at Milan in the ſixteenth century, and is greatly diſtinguiſhed for his claſſical learning. He tranſlated from Greek into Latin the "Deipnoſophiſtæ of Athenæus," the "Rhetoric of Hermogenes," and he publiſhed poems of his own in both theſe languages. In 1581 he publiſhed a hiſtory of his own times from 1545 to 1572, but his principal work is a ſyſtem of mythology entitled, "Mythologiæ, ſive Explicationis Fabularum, lib. x." It was dedicated to Charles IX. of France. He died in 1589, and on account of his love of allegory and myſticiſm he was denominated by Joſeph Scaliger "Homo futiliſſimus." Moreri.

Comes *Domeſticorum Equitum et Peditum*: Colonels of the archers of the body-guard of the Roman emperors. Thoſe archers were all of them choſen men of Armenia; and their number amounted to ſeven thouſand five hundred.

COMESSAZZA, in *Geography*, a river of Italy, which runs into the Oglio; 9 miles N.E. of Sabionetta.

COMESSAZZO, a town of Italy, in the duchy of Mantua, $3\frac{1}{2}$ miles N. of Sabionetta.

COMESUS, a lake of America, in the ſtate of New York; 27 miles S. of the lake of Ontario.

COMET, in *Aſtronomy*, a heavenly body, in the planetary region, appearing ſuddenly, and again diſappearing: and during the time of its appearance moving in a proper, though very eccentric orbit, like a planet. Comets, like the planets, move in different planes, but the motion of ſome of them is direct, and that of others retrograde.

Comets, popularly called *blazing ſtars*, have this to diſtinguiſh them from the other ſtars, that they are uſually attended with a long train of light, always oppoſite to the ſun, and which is of a fainter luſtre, the farther it is from the body. Hence ariſes a popular diviſion of comets into three kinds, viz. *bearded*, *tailed*, and *hairy comets*; though in effect this diviſion rather relates to the ſeveral circumſtances of the ſame comet, than to the phenomena of ſeveral.

Thus, when the comet is eaſtward of the ſun, and moves from it, it is ſaid to be *bearded*, becauſe the light precedes it in manner of a beard. When the comet is weſtward of the ſun, and ſets after it, it is ſaid to be *tailed*, becauſe the train follows it in manner of a tail. Laſtly, when the comet and the ſun are diametrically oppoſite, (the earth being between them), the train is hid behind the body of the comet, excepting a little that appears around it in form of a border of hair, or *coma*, whence it is called *hairy*, and whence the name of comet is derived.

Comets, *nature of*.—As to the nature of comets, the infrequency of their appearance, together with the ſeeming irregularities of their phenomena, have left philoſophers of ancient, and even more modern times, much in the dark. Thoſe who lived before Ariſtotle, accounted for them by ſuppoſing the heavenly ſpaces full of an infinite number of ſtars; and many of them too remote, or too ſmall, to have ever come under the notice of aſtronomers; theſe inviſible ſtars they farther ſuppoſed to move by their own proper motion every way; finiſhing their courſes in very unequal times. Now, a comet, according to them, was a vaſt heap or aſſemblage of theſe little ſtars, meeting together, by reaſon of the inequality of their motions, and uniting into a viſible maſs; which muſt again diſappear, as thoſe ſtars ſeparated, and each proceeding in its courſe. But how thoſe ſtars ſhould thus meet, coaleſce, and form a body, which in all poſitions of the ſun ſhould reſemble a tail, and again ſeparate, is a myſtery.

This opinion, therefore, Ariſtotle eaſily overturned: ſubſtituting another in its ſtead. According to Ariſtotle, comets were only a kind of tranſient fires or meteors, conſiſting of exhalations raiſed to the upper region of the air, and there ſet on fire; far below the moon's courſe. But neither is this hypotheſis more juſt than the other: for on this principle, the light of the comet, being independent of the ſun, would be diſperſed every way alike, without any appearance of a train, or tail, which is contrary to the phenomena. Moreover, they are obſerved at the ſame time in places on the earth very remote from each other. Beſides, the modern aſtronomers who have meaſured the diſtance between the comets and the earth, find that the comets have no ſenſible diurnal parallax; which could not be, were they not much more remote than the moon, whoſe parallax is ſenſible: and yet as they have a ſenſible annual parrallax, they are not ſo remote as the fixed ſtars. Indeed, there were ſome, Pliny tells us, among the ancients, who, "had juſter notions; who took theſe ſtars to be perpetual, and believed they moved in their proper orbs; but were never ſeen, unleſs when left by the ſun." Ariſtotle, in his firſt book of Meteors, mentions this doctrine of the ancient philoſophers; and obſerves, that ſome of the Italians, called Pythagoreans, ſaid, that a comet is one of the planets, but that they do not appear unleſs after a long time, and are ſeen but for a ſhort time, which happens alſo to Mercury. Apollonius Myndius declared, that he took comets for regular ſtars; affirming alſo, that the comets were reckoned by the Chaldæans among the planets, and to have their periods like them. He alſo ventured to foretel, that one day the periods and laws of their motion would be diſcovered. And more fully Seneca, Quæſt. Nat. lib. vii. He had himſelf ſeen at leaſt two comets, one in the reign of Claudius, the other in that of Nero; beſides that which he ſaw in his youth, a little before the death of Auguſtus, which in one place he calls a comet, and in another a prodigy. He intimates that he thought them above the moon, and argues ſtrongly againſt thoſe who imagined that they were meteors elevated into the air by winds, or who held ſome other abſurd opinions concerning them. "I am not of the common opinion," ſays he, "nor do I take a comet to be a ſudden fire, but eſteem it among the eternal works of nature." *Quid autem miramur cometas, tam rarum mundi ſpectaculum, nondum teneri legibus certis, nec initia illorum fineſque innoteſcere, quorum ex ingentibus nec intervallis recurſus eſt? Veniet tempus quo iſta quæ nunc latent, in lucem dies extrahat, & longioris ævi diligentia. Veniet tempus quo poſteri noſtri tam aperta nos neſciſſe mirentur. Erit qui demonſtret aliquando, in quibus cometæ partibus errent; cur tam ſe ducti a cæteris errent, quanti qualeſque ſint.*

This prediction we have ſeen accompliſhed in our days by the great ſir Iſaac Newton; whoſe doctrine concerning them will appear in the ſequel of this article. Seneca recommended it to aſtronomers to keep a catalogue of the comets, in order to be able to determine whether they returned at certain periods. The authority of Ariſtotle, however, long prevailed; and comets were generally conſidered as meteors, exiſting in our atmoſphere, till the time of Tycho Brahe. This excellent aſtronomer was the firſt among the moderns, who, after diligently obſerving the comet of 1577, and finding that it had no ſenſible diurnal parallax, aſſigned it its true place in the planetary regions. (See his book De Cometa, anni 1577.)

Although few comets have approached ſo near the earth as to have a diurnal parallax, they afford ſufficient indications of an annual parallax; that is, the revolution of the earth in her orbit cauſes their apparent motion to be very different from what it would be, if they were viewed from the ſun, or any fixed place. See the firſt of the phenomena recited in the ſequel. This ſhews that they are not ſo diſtant as the fixed ſtars, which have no annual parallax; and, as Hevelius obſerves, affords a proof of the earth's revolution round the ſun; for, without ſuppoſing that, theſe motions of comets are inexplicable. Tycho was preceded by Kepler, who, in his book "De Cometis," concluded from obſervations of the comets which appeared in 1607 and 1618, that comets move freely through the planetary orbs, with a motion not much different from a rectilineal one; but of what kind he could not preciſely determine. He was followed by Hevelius, an accurate obſerver of the heavenly bodies, who found, by his own obſervations of two comets that appeared in his time, that they were not ſubject to diurnal parallax; that calculations of their places, made upon a ſuppoſition that they moved in ſtraight lines, did not agree with their true places; but that their orbits were concave towards the ſun; and concluded, that they moved in parabolic trajectories.

Hevelius, from a great number of obſervations, propoſes it as his opinion, that the comets, like the ſolar maculæ or ſpots, are formed and condenſed out of the groſſer exhalations of his body: or that they are generally in the atmoſphere of a planet, and diſcharged from it, partly by the rotation of the planet, and then revolved about the ſun in a parabola by the force of projection and its tendency towards the ſun, in the ſame manner as a projectile upon the earth's ſurface deſcribes a parabola. In which notion he agrees nearly with Kepler, who maintains, that comets are generated in the æther in vaſt numbers, like fiſhes in the ocean; though they do not all become viſible; either becauſe of their ſmallneſs, or becauſe they lie a long time under the horizon.

But ſir Iſaac Newton has ſhewn the fallacy of this hypotheſis, by proving that the comet of 1680, in its paſſage through the neighbourhood of the ſun, would have been diſſipated, had it conſiſted of exhalations of the ſun and planets: for the heat of the ſun, it is allowed, is as the denſity of his rays, i. e. reciprocally as the ſquares of the diſtances of places from the ſun. Wherefore, ſince the diſtance of that comet in its perihelion, December the 8th, was obſerved to be to the diſtance of the earth from the ſun, nearly as 6 to 1000; the ſun's heat in the comet at that time, was to his heat with us at midſummer, as 1000000 to 36, or 28000 to 1.

And again, finding by experiment, that the heat of boiling water is little more than three times the heat of our dry earth, when expoſed to the midſummer's ſun; and aſſuming the heat of red-hot iron to be about three or four times as great as that of boiling water; he thence concludes, that the heat of the dried earth, or body of the comet in its perihelion, muſt be near 2000 times as great as that of red-hot iron.

Such an immenſe heat once acquired in its perihelion, the comet muſt be a long time in cooling again. The ſame author computes, that a globe of red-hot iron, of the dimenſions of our earth, would ſcarce be cool in 50000 years. If then the comet be ſuppoſed to cool 100 times as faſt as red-hot iron; yet ſince its heat was 2000 times greater, ſuppoſing it of the bigneſs of the earth, it would not be cool in a million of years.

James Bernouilli, in his "Syſtema Cometarum," ſuppoſes ſome primary planet revolving round the ſun in the ſpace of four years and one hundred and fifty-ſeven days; and at the diſtance, from his body, of 2583 ſemidiameters of the magnus orbis; this planet, he concludes, either from its vaſt diſtance, or ſmallneſs, to be inviſible to us: but, however, to have, at various diſtances from him, ſeveral ſatellites moving round him, and ſometimes deſcending as low as the orbit of Saturn; and that theſe becoming viſible to us, when in their perigæum, are what we call comets.

Des Cartes advances another opinion: he conjectures that comets are only ſtars, formerly fixed like the reſt, in the heavens; but which becoming by degrees covered with maculæ, or ſpots, and at length wholly robbed of their light, cannot keep their place, but are carried off by the vortices of the circumjacent ſtars; and, in proportion to their magnitude and ſolidity, moved in ſuch manner as to be brought nearer the orb of Saturn; and thus coming within reach of the ſun's light, rendered viſible.

But the vanity of all theſe hypotheſes abundantly appears from the phenomena of comets; the chief of which we ſhall enumerate; as being the teſt by which all theories are to be tried.

Firſt, then, thoſe comets which move according to the order of the ſigns, do all, a little before they diſappear, either advance ſlower than uſual, or elſe go retrograde, if the earth be between them and the ſun; and more ſwiftly, if the earth be ſituate in a contrary part. On the other hand, thoſe which proceed contrary to the order of the ſigns, proceed more ſwiftly than uſual, if the earth be between them and the ſun; and more ſlowly, or go retrograde, when the earth is in a contrary part.

2. So long as their velocity is increaſed, they move, nearly, in great circles; but towards the end of their courſe, they deviate from thoſe circles; and as often as the earth proceeds one way, they go the contrary way.

3. They move in ellipſes, having one of their foci in the centre of the ſun; and by radii drawn to the ſun, deſcribe areas proportionable to the times.

4. The light of their bodies, or nuclei, increaſes in their receſs from the earth toward the ſun; and on the contrary, decreaſes in their receſs from the ſun.

5. Their tails appear the largeſt and brighteſt, immediately after their tranſit through the region of the ſun, or after their perihelion.

6. The tails always decline from a juſt oppoſition to the ſun towards thoſe parts which the bodies, or nuclei, paſs over, in their progreſs through their orbits.

7. This declination, *cæteris paribus*, is the ſmalleſt, when the heads, or nuclei, approach neareſt the ſun: and is leſs, ſtill, nearer the nucleus of the comet, than towards the extremity of the tail.

8. The tails are ſomewhat brighter, and more diſtinctly defined in their convex than in their concave part.

9. The tails always appear broader at their upper extreme than near the centre of the comet.

10. The tails are always tranſparent, and the ſmalleſt ſtars appear through them.

Theſe are the chief phenomena of comets; which it is evident, cannot eaſily be reconciled with the wild notions of the ancients, and the weak conjectures of many of the moderns.

"The comets," ſays ſir Iſaac Newton, "are compact, ſolid, fixed, and durable bodies: in one word, a kind of planets; which move in very oblique orbits, every way with the greateſt freedom; perſevering in their motions, even againſt the courſe and direction of the planets; and their tail is a very thin ſlender vapour, emitted by the head or nucleus of the comet, ignited or heated by the ſun."

This at once ſolves all the foregoing phenomena: for, 1. "It is evident, that thoſe which proceed according to the order of the ſigns, a little before they diſappear, muſt move more ſlowly, or appear retrograde, if the earth be betwixt them and the ſun; and ſwifter if the earth be in a contrary part. On the contrary, thoſe proceeding againſt the order of the ſigns," &c. For ſince this courſe is not among the fixed ſtars, but among the planets; as the motion of the earth either conſpires with them, or goes againſt them; their appearance, with regard to the earth, muſt be changed; and, like the planets, they muſt ſometimes appear ſwifter, ſometimes ſlower, and ſometimes retrograde.

2. "When the comets move the ſwifteſt, they muſt proceed in ſtraight lines; but in the end of their courſe, decline," &c. Becauſe, in the end of their courſe, when they recede almoſt directly from the ſun, that part of the apparent motion which ariſes from the parallax, muſt bear a greater proportion to the whole apparent motion.

3. "The comets muſt move in ellipſes, having one of their foci in the centre of the ſun." Becauſe they do not wander precariouſly from one fictitious vortex to another; but, making a part of a ſolar ſyſtem, return perpetually, and run a conſtant round.

Hence, their elliptic orbits being very long and eccentric they become inviſible, when in that part moſt remote from the ſun.

From conſidering the curvity of the paths of comets, ſir Iſaac concludes, that when they diſappear, they are much beyond the orb of Jupiter; and that in their perihelion they frequently deſcend below the orbit of Mars, and the inferior planets.

4. "The light of their nuclei muſt increaſe in their receſs from the ſun, and *vice verſâ.*" Becauſe as they are in the regions of the planets, their acceſs toward the ſun bears a conſiderable proportion to their whole diſtance.

From obſervations of the comet of 1680, ſir Iſaac Newton found, that the vapour in the extremity of the tail, January 25th, began to aſcend from the head before December 11th; and had therefore ſpent more than forty-five days in its aſcent; but that all the tail which appeared December 10th, aſcended in the ſpace of thoſe two days, then juſt paſt ſince its perihelion. The vapour, therefore, at the beginning, when the comet was near the ſun, aſcended with a prodigious ſwiftneſs; and afterwards continued to aſcend with a motion retarded by the gravity of its particles; and by that aſcent increaſed the length of the tail; but the tail, notwithſtanding its length, conſiſted almoſt wholly of vapours, which had aſcended from the time of its perihelion; and the vapour which aſcended firſt, and compoſed the extreme of the tail, did not vaniſh till it was too far from the ſun to be illuminated by him, and from us to be viſible. Hence alſo, the tails of comets that are ſhorter, do not aſcend with a quick and continual motion from the head, and then preſently diſappear; but are permanent columns of vapours and exhalations, gathered from the head, by a very gentle motion, and a great ſpace of time; which yet, by participating of that motion of their heads they had at the beginning, continue eaſily to move along with their heads through the celeſtial regions: whence alſo the vacuity of thoſe regions is argued. See VACUUM.

5. "Their tails muſt appear the largeſt and brighteſt immediately after their tranſit through the region of the ſun." Becauſe, then, their heads being the moſt heated, will emit the moſt vapours.

From the light of the nucleus, or apparent ſtar, we infer their vicinity to the earth, and that they are by no means in the region of the fixed ſtars, as ſome have imagined; ſince, in that caſe, their heads would be no more illuminated by the ſun, than the planets are by the fixed ſtars.

6. "The tails muſt ſtill decline from a diſtinct oppoſition to the ſun, towards the parts which the heads paſs over, in their progreſs through their orbits." Becauſe all ſmoke, or vapour, emitted from a body in motion, tends upwards obliquely, ſtill receding from that part, towards which the ſmoking body proceeds.

7. "That declination will be ſtill the leaſt near the nucleus of the comet; and when the comet is neareſt the ſun." Becauſe the vapour aſcends more ſwiftly near the head of the comet, than in the higher extremity of its tail; and when the comet is at a leſs diſtance from the ſun than when at a greater.

8. "The tail is brighter, and better defined in its convex part than in its concave." Becauſe the vapour in the convex part, which goes firſt, being ſomewhat nearer and denſer, reflects the light more copiouſly.

9. "The tail muſt appear broader towards the higher extremity of the comet than towards the head." Becauſe the vapour in a free ſpace is perpetually rarefied and dilated.

10. "The tails muſt be tranſparent." Becauſe conſiſting of infinitely thin vapour, &c.

Thus accurately does the hypotheſis tally to the phenomena.

COMETS, *phaſes of*.—The nuclei, which we alſo occaſionally call the *heads* and *bodies* of comets, viewed through a teleſcope, ſhew a very different face from thoſe of the fixed ſtars, or planets. They are liable to apparent changes, which ſir Iſaac Newton aſcribes to changes in the atmoſphere of comets; and this opinion was confirmed by obſervations of the comet in 1744. Hiſt. Acad. Scienc. 1744. Sturmius tells us, that, obſerving the comet of 1680, with a teleſcope, it appeared like a coal dimly glowing, or a rude maſs of matter illumined with a duſky fumid light, leſs ſenſible at the extremes than in the middle; rather than as a ſtar, which appears with a round diſk, and a vivid light.

Hevelius obſerved of the comet of 1661, that its body was of a yellowiſh colour, very bright, and conſpicuous, but without any glittering light: in the middle was a denſe ruddy nucleus, almoſt equal to Jupiter, encompaſſed with a much fainter, thinner matter. February 5th, its head was ſomewhat bigger and brighter, of a gold colour; but its light more duſky than the reſt of the ſtars: here, the nucleus appeared divided into ſeveral parts. February 6th, the diſk was leſſened; the nuclei ſtill exiſted, though leſs than before: one of them, on the lower part of the diſk, on the left, much denſer and brighter than the reſt, its body round, and repreſenting a very lucid little ſtar: the nuclei ſtill encompaſſed with another kind of matter. February 10th, the head ſomewhat more obſcure, and the nuclei more confuſed, but brighter at top than bottom. February 13, the head diminiſhed much, both in magnitude and brightneſs. March 2d, its roundneſs a little impaired, its edges lacerated, &c. March 28th, very pale and exceeding thin; its matter much diſperſed; and no diſtinct nucleus at all appearing.

Weigelius, who ſaw the comet of 1664, the moon and a little cloud illumined by the ſun at the ſame time, obſerved, that the moon, through a teleſcope, appeared of a continued luminous ſurface; but the comet very different; being perfectly like a little cloud in the horizon illumined by the ſun. From theſe obſervations it was, that Hevelius concluded comets to be like maculæ, or ſpots formed out of the ſolar exhalations.

Comets, *magnitude of.* The eſtimates that have been given by Tycho, Hevelius, and ſome others, of the magnitude of comets, are not ſufficiently accurate to be depended upon; for it does not appear, that they diſtinguiſhed between the nucleus and the ſurrounding atmoſphere. Thus Tycho computes that the true diameter of the comet in 1577, was in proportion to the diameter of the earth as 3 is to 14. Hevelius made the diameter of the nucleus of the comet of 1661 and alſo that of 1665 at the commencement of their appearances to be leſs than a 10th part of the diameter of the earth, and from the parallax and apparent magnitude of the head of the comet of 1652 on the 10th of December, he computed its diameter to be to that of the earth, as 52 to 100. By the ſame method he found the true diameter of the head of the comet of 1664 to be at one time 12 ſemi-diameters of the earth, at another time not much above 5 ſemi-diameters. The diameter of the atmoſphere is often ten or fifteen times as great as that of the nucleus; the former, in the comet of 1682, was meaſured by Flamſteed, and found to be 2′, but the diameter of the nucleus only 11 or 12″. Some comets, from the apparent magnitude and diſtance compared, have been judged to be much larger than the moon, and even equal to ſome of the primary planets. The diameter of that of 1744, when at the diſtance of the ſun from us, meaſured about 1′, and therefore its diameter muſt be about three times the diameter of the earth: at another time the diameter of its nucleus was nearly equal to that of Jupiter.

Hence it has been conjectured that ſome of the ſolar eclipſes, recorded in hiſtory, that cannot be verified by calculation from tables of the ſun and moon, have been occaſioned by the interpoſition of comets between the ſun and the earth. The eclipſes of the ſun mentioned by Herodotus (l. vii. c. 37, and l. ix. c. 10.) have been thus accounted for, and alſo the eclipſe that happened a few days before the death of Auguſtus, mentioned by Dion: and it is obſervable, that Seneca ſaw a comet the ſame year. Hiſtory records ſome comets that have appeared as large as the ſun, (vid. Seneca, N. Q. l. 7. c. 15); and, therefore, if ſuch a comet near its perigee were to come between the ſun and our earth, it would eclipſe him for a time. Some have thought that the darkneſs which occurred at our Lord's crucifixion might have been occaſioned by a comet then paſſing between the earth and the ſun. (Hevel. Cometogr. p. 540. Freret, reflexions ſur un ancien phenomene celeſte au temps d'Ogyges, Mem. de Literature, vol. xix. p. 357).

Dr. Herſchel obſerved ſeveral comets which ſeemed to him to have no nucleus. The ſix comets diſcovered by his ſiſter were of this kind, and appeared to be mere collections of vapours condenſed about a centre. Five more were obſerved by himſelf, which were nearly of the ſame nature. This circumſtance, he ſays, "throws a myſtery over their deſtination, which ſeems to place them in the allegorical view of tools, probably deſigned for ſome ſalutary purpoſes to be wrought by them; and, whether the reſtoration of what is loſt to the ſun by the emiſſion of light may not be one of theſe purpoſes, I ſhall not preſume to determine. The motion of the comet diſcovered by M. Meſſier, June, 1770, plainly indicated how much its orbit was liable to be changed by the perturbation of the planets, from which, and the little agreement that can be found between the elements of the orbits of all the comets that have been obſerved, it appears clearly that they may be directed to carry their ſalutary influence to any part of the heavens."

Comets, *Formation of the tails of.* Sir Iſaac Newton ſhews, that the atmoſphere of comets will furniſh vapour ſufficient to form their tails: this he argues from that wonderful rarefaction obſerved in our air, at a diſtance from the earth: a cubic inch of common air, at the diſtance of half the earth's diameter, or four thouſand miles, would neceſſarily expand itſelf ſo far as to fill a ſpace larger than the whole region of the planets. Since then the coma or atmoſphere of a comet, is ten times higher than the ſurface of the nucleus, counting from the centre thereof; the tail, aſcending much higher, muſt neceſſarily be immenſely rare: ſo that it is no wonder the ſtars ſhould be viſible through it.

Now, the aſcent of vapours into the tail of the comet, he ſuppoſes occaſioned by the rarefaction of the matter of the atmoſphere at the time of the perihelion. Smoke, it is obſerved, aſcends the chimney by the impulſe of the air wherein it floats; and air, rarefied by heat, aſcends by diminution of its ſpecific gravity, taking up the ſmoke along with it: why then ſhould not the tail of a comet be ſuppoſed to be raiſed after the ſame manner by the ſun? for the ſun beams do not act on the mediums they paſs through any otherwiſe than by reflexion and rarefaction.

The reflecting particles, then, being warmed by the action, will again warm the æther wherewith they are compounded; and this, rarefied by the heat, will have its ſpecific gravity, whereby it before tended to deſcend, diminiſhed by the rarefaction, ſo as to aſcend, and carry along with it thoſe reflecting particles, whereof the tail of the comet is compoſed.

This aſcent of the vapours will be promoted by their circular motion round the ſun; by means whereof, they will endeavour to recede from the ſun, while the ſun's atmoſphere, and the other matters in the celeſtial ſpaces, are either at reſt, or nearly ſo; having no motion but what they receive from the ſun's circumrotation.

Thus are the vapours raiſed into the tails of comets in the neighbourhood of the ſun, where the orbits are moſt curve; and where the comets, being within the denſer atmoſphere of the ſun, have their tails of the greateſt length.

The tails thus produced, by preſerving that motion, and at the ſame time gravitating towards the ſun, will move round his body in ellipſes, in like manner as their heads; and, by this means, will ever accompany, and freely adhere to their heads. In effect, the gravitation of the vapours towards the ſun will no more occaſion the tails of the comets to forſake their heads, and fall down towards the ſun, than the gravitation of their heads will occaſion them to fall off from their tails: but by their common gravitation, they will either fall down together to the ſun, or be together ſuſpended, or retarded. This gravitation, therefore, does not at all hinder, but that the heads and tails of comets may receive and retain any poſition towards each other, which either the above mentioned cauſes, or any other, may occaſion. The tails, therefore, thus produced in the perihelion of comets, will go off along with their heads into remote regions; and either return thence, together with the comets, after a long ſeries of years; or rather, be there loſt, and vaniſh by little and little, and the comets be left bare; till at their return, deſcending towards the ſun, ſome little ſhort tails are gradually and ſlowly produced from the heads; which afterwards, in the perihelion, deſcending down into the ſun's atmoſphere, will be immenſely increaſed.

The vapours, when they are thus dilated, rarefied and diffuſed through all the celeſtial regions, the ſame author obſerves, may probably, by little and little, by means of their own gravity, be attracted down to the planets, and become intermingled with their atmoſpheres.

He adds, that for the conſervation of the water, and moiſture of the planets, comets ſeem abſolutely requiſite; from whoſe condenſed vapours and exhalations, all that moiſture which is ſpent in vegetations and putrefactions, and turned into dry earth, &c. may be reſupplied and recruited. For all vegetables grow and increaſe wholly from fluids; and, again, as to their greateſt part, turn, by putrefaction, into earth again; and earthly ſlime being perpetually precipitated to the bottom of putrefying liquors. Hence, the quantity of dry earth muſt continually increaſe, and the moiſture of the globe decreaſe, and at laſt be quite evaporated, if it has not a continual ſupply from ſome part or other of the univerſe. And I ſuſpect, adds our great author, that the ſpirit, which makes the fineſt, ſubtileſt, and the beſt part of our air, and which is abſolutely requiſite for the life and being of all things, comes principally from the comets. So far are they from portending any hurt or miſchief to us which the natural fears of men are apt to ſuggeſt from the appearance of any thing that is uncommon and aſtoniſhing.

On this principle, there ſeems to be ſome foundation for the popular opinion of preſages from comets; ſince the tail of a comet thus intermingled with our atmoſphere, may produce changes very ſenſible in animal and vegetable bodies.

But the tranſmutation of water into earth is now juſtly exploded: Woodward, Boerhaave, and others, having obſerved that water is only an agent in conveying the nutritious matter to vegetable bodies, and not that matter itſelf.

Another uſe which ſir Iſaac Newton conjectures comets may be deſigned to ſerve, is that of recruiting the ſun with freſh fuel, and repairing the conſumption of his light by the ſtreams continually ſent forth in every direction from that luminary. In ſupport of this conjecture he obſerves, that comets in their perihelion may ſuffer a diminution of their projectile force, by the reſiſtance of the ſolar atmoſphere; ſo that by degrees their gravitation towards the ſun may be ſo far increaſed, as to precipitate their fall into his body. Thus alſo, fixed ſtars which have been gradually waſted, may be ſupplied with freſh fuel, acquire new ſplendour, and be taken for new ſtars: of this kind are thoſe fixed ſtars, which appear on a ſudden, or ſhine with a ſurpriſing brightneſs at firſt, and afterwards vaniſh by degrees.

There have been various conjectures about the generation of the tails of comets. Apian, Cardan, Tycho Brahe, and ſome others, apprehended that they were produced by the ſun's rays tranſmitted through the nucleus of the comet, which they ſuppoſed to be tranſparent, and there refracted as in a lens of glaſs, ſo as to form a beam of light behind the comet. But this cannot be the caſe, becauſe the figure of a comet's tail does not correſpond to ſuch a refraction, and alſo becauſe ſuch refracted light would not be ſeen by an eye placed ſideways to it, unleſs it fell upon ſome reflecting ſubſtance denſer than the circumambient æther. Kepler ſuppoſed, that the rays of the ſun carry away ſome of the groſs parts of the comet which reflect the ſun's rays, and give the appearance of a tail. Hevelius thought, that the thinneſt parts of the atmoſphere of a comet are rarefied by the force of the heat, and driven from the fore-part and each ſide of the comet towards the parts turned from the ſun. Des Cartes accounted for the phenomenon of the tail by the refraction of light from the head of the comet to the eye of the ſpectator. If this were the caſe, the planets and principal fixed ſtars muſt have tails alſo; for their rays paſs through the ſame medium before they reach our eyes, as light from the comets does. Mairan ſuppoſes that the tails are formed out of the luminous matter that compoſes the ſun's atmoſphere, which is ſuppoſed to extend as far as the orbit of the earth, and to furniſh matter for thoſe northern lights called the *Aurora Borealis*, which ſee. M. De la Lande combines this hypotheſis with that of Newton above recited. He thinks that part of the vapour which forms them ariſes out of the atmoſphere rarefied by heat, and is puſhed forward by the force of the light ſtreaming from the ſun; and alſo that a comet paſſing through the ſun's atmoſphere is drenched therein, and carries away ſome of it. Mr. Rowning, who is not ſatisfied with ſir Iſaac's opinion, accounts for the tails of comets in the following manner. It is well known, ſays he, that when the light of the ſun paſſes through the atmoſphere of any body, as the earth, that which paſſes on one ſide, is by the refraction thereof made to converge toward that which paſſes on the oppoſite one; and the convergency is not wholly effected either at the entrance of the light into the atmoſphere, or at its going out; but beginning at its entrance, it increaſes in every point of its progreſs. It is alſo agreed that the atmoſpheres of the comets are very large and denſe. He therefore ſuppoſes that by ſuch time as the light of the ſun has paſſed through a conſiderable part of the atmoſphere of a comet, the rays thereof are ſo far refracted toward each other, that they then begin ſenſibly to illuminate it, or rather the vapours floating therein; and ſo render that part they have yet to paſs through viſible to us: and that this portion of the atmoſphere of a comet, thus illuminated, appears to us in form of a beam of the ſun's light, and paſſes under the denomination of a comet's tail. Rowning's Natural Philoſophy, part iv. chap. 11.

We have an inquiry into the cauſe of the tails of comets, by Mr. Euler, in the Mem. de l'Acad. de Berlin, tom. ii. p. 117, ſeq. He thinks there is a great affinity between theſe tails, the zodiacal light, and the Aurora borealis; and that the common cauſe of them all, is the action of the ſun's light on the atmoſphere of the comets, of the ſun, and of the earth. He ſuppoſes that the impulſe of the rays of light on the atmoſphere of comets, may drive ſome of the finer particles of that atmoſphere far beyond its limits; and that this force of impulſe combined with that of gravity towards the comet, would produce a tail, which would always be in oppoſition to the ſun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, muſt vary the poſition and figure of the tail, giving it a curvature, and deviation from a line drawn from the centre of the ſun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and that the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be ſo great, that the force of the ſun's rays may produce a new tail, before the old one can follow; in which caſe the comet might have two or more tails. The poſſibility of this is confirmed by the comet of 1744, which was obſerved to have ſeveral tails while it was in its perihelion. See AURORA *borealis*, and ZODIACAL *light*.

Dr. Hamilton urges ſeveral objections againſt the Newtonian hypotheſis; obſerving, that we have no proof of the exiſtence of a ſolar atmoſphere; and if we had, that when the comet is moving in its perihelion, in a direction at right angles to the direction of its tail, the vapours which then ariſe partaking of the great velocity of the comet, and being alſo ſpecifically lighter than the medium in which they move, muſt ſuffer a much greater reſiſtance than the denſe body of the comet does, and therefore ought to be left behind, and would not appear oppoſite to the ſun; and afterwards they ought to appear towards the ſun. Beſides, if the ſplendour of the tails be owing to the reflexion and refraction of the ſun's rays, it ought to diminiſh the luſtre of the ſtars ſeen through it; which would have their light reflected and refracted in like manner; and conſequently their brightneſs would be diminiſhed. He concludes that the tail of a comet is formed of matter which has not the power of refracting or reflecting the rays of light; but that it is a lucid or ſelf-ſhining ſubſtance; and from its ſimilarity to the *Aurora borealis*, produced by the ſame cauſe, and a proper electrical phenomenon. Dr. Hamilton ſupports his opinion by the following arguments. A ſpectator, at a diſtance from the earth, would ſee the Aurora borealis in the form of a tail oppoſite to the ſun, as the tail of a comet lies. The Aurora borealis has no effect upon the ſtars ſeen through it, nor has the tail of a comet. The atmoſphere is known to abound with electric matter, and the appearance of the electric matter in vacuo reſembles exactly that of the Aurora borealis, which, from its great altitude, may be conſidered to be in as perfect a vacuum as we can make. The electric matter in vacuo ſuffers the rays of light to paſs through, without being affected by them. The tail of a comet does not expand itſelf ſideways, nor does the electric matter. Hence, he ſuppoſes the tails of comets, the Aurora borealis, and the electric fluid to be the ſame kind of matter. As a further confirmation of this opinion it may be added, that the comet in 1607 appeared to ſhoot out the end of its tail. Le P. Cyſat remarked the undulations of the tail of the comet in 1618. Hevelius obſerved the ſame in the tails of the comets in 1652 and 1661. M. Pingrè noticed the ſame appearance in the comet of 1769: and theſe are circumſtances ſimilar to the Aurora borealis. Dr. Hamilton conjectures, that the uſe of the comets may be to bring the electric matter, which continually eſcapes from the planets, back into the planetary regions. Theſe arguments very much corroborate this hypotheſis; and if it be true, we may further add, that the tails are hollow; for if the electric fluid only proceed in its firſt direction and do not diverge ſideways, the parts directly behind the comet will not be filled with it; and this thinneſs of the tails will account for the appearance of the ſtars through them. Dr. Halley ſeemed inclined to this hypotheſis, when he ſaid, that the ſtreams of light in an Aurora borealis ſo much reſembled the long tails of comets, that at firſt ſight they might well be taken for ſuch: and that this light ſeems to have a great affinity to that which the effluvia of electric bodies emit in the dark. Phil. Tranſ. N° 347. Hamilton's Philoſophical Eſſays, p. 91, &c.

Hevelius particularly informs us, that he obſerved the comet of 1665 to caſt a ſhadow upon the tail, for in the middle of its length there appeared a dark line. Caſſini alſo obſerved in the tail of the comet of 1680 a darkneſs in the middle of the tail; and the ſame appearance was taken notice of by a curious obſerver in the tail of the comet of 1744. The lengths of the tails of comets are various, and depend on a variety of circumſtances. Longomontanus mentions a comet that in 1618, December the 10th, had a tail which appeared under an angle of 104°: that of 1680 appeared under an angle of 70°, according to ſir I. Newton, and very brilliant: the comet of 1744 had a tail, which at one time appeared to extend 16° from its body; and which, allowing the ſun's parallax to be 10″, muſt have been above 23 millions of miles in length. The diameter of its nucleus was nearly equal to that of Jupiter. The tail of the comet of 1759 appeared, according to M. Pingré, under an angle of 90°; but the light was very faint. The length of a comet's tail may be thus found. Let S (*Plate* IV. *Aſtronomy. fig.* 23.) be the ſun, E the earth, C the comet, C L the tail when directed from the ſun; then, knowing the place of the comet, we know the angle E C L, E C, and the angle C E L, the angle under which the tail appears; hence we find C L the length of the tail. If the tail deviate by any angle L C M, found from obſervation, we ſhall then know the angle E C M, with C E, and the angle C E M, to find C M.

M. Fatio has ſuggeſted that ſome of the comets have their nodes ſo very near the annual orbit of the earth; that if the earth ſhould happen to be found in that part next the node, at the time of a comet's paſſing by; as the apparent motion of the comet will be incredibly ſwift, ſo its parallax will become very ſenſible; and the proportion thereof to that of the ſun will be given: whence ſuch tranſits of comets will afford the beſt means of determining the diſtance of the earth and ſun.

The comet of 1472, *v. gr.* had a parallax above twenty times greater than the ſun's: and if that of 1618 had come down in the beginning of March to its deſcending node, it would have been much nearer the earth, and its parallax much more notable. But, hitherto, none has threatened the earth with a nearer appulſe than that of 1680: for, by calculation, Dr. Halley finds that November 11th, 1 h. 6 min. P. M. that comet was not above one ſemidiameter of the earth, to the northward of the way of the earth; at which time had the earth been in that part of its orbit, the comet would have had a parallax equal to that of the moon: what might have been the conſequence of ſo near an appulſe, a contact, or, laſtly, a ſhock of the celeſtial bodies?

If the earth had been at this time in that part of her orbit neareſt to that node of the comet, through which it paſſed, their mutual gravitation muſt have cauſed a change in the plane of the orbit of the earth, and in the length of our year. Dr. Halley adds, that if ſo large a body, with ſo rapid a motion as that of this comet near its perihelion, were to ſtrike againſt our earth, a thing by no means impoſſible, the ſhock might reduce this beautiful frame to its original chaos. Whiſton, who, from Flamſteed's meaſure of the apparent diameter of this comet, concluded its nucleus to be about ten times as big as the moon, or equal to a fourth part of our earth, attributes the univerſal deluge, in the time of Noah, to its near approach. His opinion was, that the earth paſſing through the atmoſphere of the comet, attracted from it a conſiderable part of the waters of the flood; that the proximity of the comet raiſed a great tide in the ſubterraneous waters, ſo that the outward cruſt of the earth was changed from ſpherical to oval; that this could not be done without making fiſſures and cracks in it; that through theſe fiſſures the ſubterranean waters were forced, in conſequence of the change of the hollow of the earth into a leſs capacious form;—that, along with the water thus ſqueezed up upon the ſurface of the earth, much ſlime or mud would riſe; which, together with the groſſer parts of the comet's atmoſphere, would, after the ſubſiding of the water partly into the fiſſures and partly into the lower parts of the earth to form the ſea, cover all over to a conſiderable depth the antediluvian earth:—and thus he accounts for trees and bones of animals being found at very great depths in the earth. He alſo ſuppoſed, that before the fall the earth revolved round the ſun in the plane of the ecliptic, keeping always the ſame points of its ſurface towards the ſame fixed ſtars; by this means, as every meridian would come to the ſun but once in a whole revolution, a day and a year were then the ſame: but that a comet ſtriking obliquely upon the earth gave it the diurnal rotation. Moreover, he apprehended, that the antediluvian year conſiſted of 360 days: but that the additional matter depoſited upon the earth from the atmoſphere of the comet at the time of the deluge, ſo retarded its revolution round the ſun, that it is not now performed in leſs than 365 days and about a quarter.

The ſame comet, he imagined, would probably, by coming near the earth after being heated to an immenſe degree in its perihelion, be the inſtrumental cauſe of that great cataſtrophe, the general conflagration, foretold in the Sacred Writings, and from ancient tradition, mentioned by heathen writers. See CONFLAGRATION, DELUGE, and *Theory of the* EARTH.

COMETS, *diſtance of.* The analogy between the periodical time of the planets, and their diſtances from the ſun, diſcovered by Kepler, takes place alſo in the comets. Hence, the mean diſtance of a comet from the ſun may be found by comparing its period with the time of the earth's revolution round the ſun: thus, the period of the comet that appeared in 1531, 1607, 1682, and 1759, being about 76 years, its mean diſtance is found by this proportion; as 1 the ſquare of one year, the earth's periodical time, is to 5776 the ſquare of 76, the comet's periodical time, ſo is 1000000 the cube of 100, the earth's mean diſtance from the ſun, to 5776000000 the cube of the comet's mean diſtance; the cube root of which is 1794, the mean diſtance itſelf, in ſuch parts as the mean diſtance of the earth contains 100. If the perihelion diſtance of this comet 58 be taken from 3588 double the mean diſtance, we ſhall have the aphelion diſtance 3530 of ſuch parts as the diſtance of the earth contains 100; and this is a little more than 35 times the diſtance of the earth from the ſun. By a like method the aphelion diſtance of the comet of 1680 comes out 138 times the mean diſtance of the earth from the ſun, ſuppoſing its period to be 575 years; ſo that this comet in its aphelion goes to more than 14 times the diſtance from the ſun that Saturn does.

The limit of a comet's diſtance may be very eaſily aſcertained from its tail, it being ſuppoſed to be directed from the ſun. Let S (*fig.* 24.) be the ſun, E the earth, E T the line in which the head of the comet appears, E W the line in which the extremity of the tail is obſerved, and draw S T parallel to E W; then the comet is within the diſtance E T; for if the comet were at T, the tail would be directed in a line parallel to E W, and therefore it could never appear in that line. T E W is known by obſervation, and conſequently its equal E T S, together with T E S, the angular diſtance of the comet from the ſun, and E S, to find S T the limit. E.G. On December 21, 1680, the diſtance of the comet from the ſun was 32° 24′, and length of the tail 70°; hence S T : S E :: ſin. 32° 24′ : ſin. 70° :: 4 : 7 nearly; conſequently the comet's diſtance from the ſun was leſs than $\frac{4}{7}$ of the earth's diſtance from the ſun. Hence ſir Iſaac Newton deduced this concluſion, that all comets, whilſt they are viſible, are not further diſtant from the ſun than three times the earth's diſtance from the ſun. This muſt, however, depend upon the goodneſs of the teleſcope, and magnitude of the comet. Vince's Aſtr. vol. i. p. 446.

COMETS, *motion of.* If the paths of comets be ſuppoſed directly parabolical, as ſome have imagined, it would follow, that being impelled toward the ſun by a centripetal force, they deſcend as from ſpaces infinitely diſtant; and by their falls acquire ſuch a velocity, as that they may again run off into the remoteſt regions; ſtill moving upwards, with ſuch a perpetual tendency as never to return. But the frequency of their appearance, and their degree of velocity, which does not exceed what they might acquire by their gravity towards the ſun, ſeem to put it paſt doubt that they move, planet-like, in elliptic orbits, though exceedingly eccentric; and ſo return again, though after very long periods.

The apparent velocity of the comet of 1472, as obſerved by Regiomontanus, was ſuch as to carry it through 40° of a great circle in 24 hours: and that of 1770 was obſerved to move through more than 45° in the laſt 25 hours.

G. S. Doërfell, miniſter at Plaven in Upper Saxony, made obſervations upon the comet of 1680, and found that its motion might very well be repreſented by a parabola, having the ſun in its focus; but not underſtanding the laws by which the motion of a body in a parabola is regulated, he erred conſiderably in his parabola, making the perihelion diſtance about 12 times greater than it was. This was publiſhed five years before the "Principia" of Newton, in which this illuſtrious author proved that Kepler's law, by which the planetary motions are regulated, was a neceſſary reſult of his theory of gravity; whence it immediately followed, that comets were governed by the ſame law; and the obſervations upon them agreed ſo accurately with his theory, as to leave no doubt of its truth.

Newton, Flamſteed, Halley, and the Engliſh aſtronomers, &c. ſeem ſatisfied of the return of the comets. Caſſini, and others of the French, thought it highly probable; but De la Hire, and others, oppoſed it.

Thoſe on the affirmative ſide ſuppoſe the comets to deſcribe orbits prodigiouſly eccentric, inſomuch that we can only ſee them in a very ſmall part of their revolution: out of this, they are loſt in the immenſe ſpaces; hid not only from our eyes, but from our teleſcopes. That little part of their orbit near us, M. Caſſini, &c. has found to paſs between the orbits of Venus and Mars.

For the reaſons of the return of comets, M. Caſſini gives theſe which follow. 1. In conſidering the courſe of the comets, with regard to the fixed ſtars, they are found to keep a conſiderable time in the arc of a great circle, *i. e.* a circle whoſe plane paſſes through the centre of the earth: indeed, they deviate a little from it, chiefly towards the end of their appearance; but this deviation is common to them with the planets.

2. Comets, as well as planets, appear to move ſo much the faſter as they are nearer the earth; and when they are at equal diſtances from their perigee, their velocities are nearly the ſame.

By ſubtracting from their motion the apparent inequality of velocity occaſioned by their different diſtances from the earth, their equal motion might be found: but we ſhould not be certain this motion were their true one; becauſe they might have conſiderable inequalities, not diſtinguiſhable in that ſmall part of their orbit viſible to us. It is, indeed, probable, their real motion, as well as that of the planets, is unequal in itſelf: and hence we have a reaſon why the obſervations made, during the appearance of a comet, cannot give the juſt period of their revolution.

3. There are no two different planets whoſe orbits cut the ecliptic in the ſame angle, whoſe nodes are in the ſame points of the ecliptic, and whoſe apparent velocity in their perigee is the ſame; conſequently, two comets ſeen at different times, yet agreeing with all thoſe three circumſtances, can only be one and the ſame comet. And this were the comets of 1577 and 1680 obſerved to do; and thoſe of 1652 and 1698; not that this exact

agreement, in theſe circumſtances, is abſolutely neceſſary to determine them the ſame comet. M. Caſſini finds the moon herſelf irregular in them all: accordingly, he is of opinion, there are ſeveral which diſagree herein, and yet may be accounted the ſame.

The great objection againſt the return of comets, is, the rarity of their appearance, with regard to the number of revolutions aſſigned to them.

In 1702, there was a comet, or rather the tail of one, ſeen at Rome, which M. Caſſini takes to be the ſame with that obſerved by Ariſtotle, and that ſince ſeen in 1668, which would imply its period to be thirty-four years. Now, it may ſeem ſtrange, that a ſtar which has ſo ſhort a revolution, and of conſequence ſuch frequent returns, ſhould be ſo ſeldom ſeen.—Again, in April, of the ſame year, 1702, a comet was obſerved by Meſſ. Bianchini, and Maraldi, ſuppoſed by the latter to be the ſame with that of 1664, both by reaſon of its motion, velocity, and direction. M. de la Hire took it to have ſome relation to another he had obſerved in 1698, which M. Caſſini refers to that of 1652. On this ſuppoſition, its period appears to be forty-three months; and the number of revolutions between 1652 and 1698, fourteen: but it is hard to ſuppoſe, that in this age, wherein the heavens are ſo narrowly watched, a ſtar ſhould make fourteen appearances unperceived; eſpecially ſuch a ſtar as this which might appear above a month together: and of conſequence be frequently diſengaged from the crepuſcula.

For this reaſon M. Caſſini was very reſerved in maintaining the hypotheſis of the return of comets, and only propoſed thoſe for planets, where the motions are eaſy and ſimple, and are reſolved without ſtraining, or allowing many irregularities.

M. de la Hire propoſes one general difficulty againſt the whole ſyſtem of the return of comets, which would ſeem to hinder any comet from being a planet: and it is this; that by the diſpoſition neceſſarily given to their courſes, they ought to appear as large at firſt as at laſt; and always increaſe, till they arrive at their greateſt proximity to the earth: or, if they ſhould chance not to be obſerved, as ſoon as they become viſible, for want of attention thereto; at leaſt it is impoſſible but they muſt frequently ſhew themſelves before they have arrived at their full magnitude and brightneſs. But he adds, that none were ever yet obſerved till they had arrived at it.

But the appearance of a comet in the month of October 1723, while at a great diſtance, ſo as to be too ſmall and dim to be viewed without a teleſcope, may ſerve to remove this obſtacle, and ſet the comets, ſtill, on the ſame footing with the planets.

Sir Iſaac Newton ſuppoſes, that as thoſe planets which are neareſt the ſun, and revolve in the leaſt orbits, are the ſmalleſt; ſo among the comets, ſuch as in their perihelion come neareſt the ſun, are the ſmalleſt, and revolve in leſſer orbits.

In order to prove that comets deſcribe ellipſes, and not parabolas or hyperbolas, Dr. Halley, in his "Synopſis of the Aſtronomy of Comets," advances the following reaſons. "Hitherto I have conſidered the orbits of comets as exactly parabolic; upon which ſuppoſition it would follow, that comets being impelled towards the ſun, by a centripetal force, would deſcend as from ſpaces infinitely diſtant; and, by their ſo falling acquire ſuch a velocity, as that they may again fly off into the remoteſt parts of the univerſe, moving upwards with a perpetual tendency, ſo as never to return again to the ſun. But ſince they appear frequently enough, and ſince none of them can be found to move with an hyperbolic motion, or a motion ſwifter than what a comet might acquire by its gravity to the ſun, it is highly probable they rather move in very eccentric elliptic orbits, and make their returns after long periods of time; for ſo their number will be determinate, and perhaps not ſo very great. Beſides, the ſpace between the ſun and the fixed ſtars is ſo immenſe, that there is room enough for a comet to revolve, though the period of its revolution be vaſtly long. Now the *latus rectum* of an ellipſis is to the *latus rectum* of a parabola, which has the ſame diſtance in its perihelion, as the diſtance in the aphelion, in the ellipſis, is to the whole axis of the ellipſis. And the velocities are in a ſubduplicate ratio of the ſame; wherefore, in very eccentric orbits, the ratio comes very near to a ratio of equality; and the very ſmall difference which happens, on account of the greater velocity in the parabola, is eaſily compenſated in determining the ſituation of the orbit. The principal uſe therefore of the table of the elements of their motions, and that indeed which induced me to conſtruct it, is, that whenever a new comet ſhall appear, we may be able to know, by comparing together the elements, whether it be any of thoſe which has appeared before, and conſequently to determine its period, and the axis of its orbit, and to foretel its return. And, indeed, there are many things which make me believe, that the comet which Apian obſerved in the year 1531, was the ſame with that which Kepler and Longomontanus more accurately deſcribed in the year 1607; and which I myſelf have ſeen return, and obſerved in the year 1682. All the elements agree, and nothing ſeems to contradict this my opinion, beſides the inequality of the periodic revolutions; which inequality is not ſo great neither, as that it may not be owing to phyſical cauſes. For the motion of Saturn is ſo diſturbed by the reſt of the planets, eſpecially Jupiter, that the periodic time of the planet is uncertain, for ſome whole days together. How much more therefore will a comet be ſubject to ſuch like errors, which riſes almoſt four times higher than Saturn, and whoſe velocity, though increaſed but a very little, would be ſufficient to change its orbit, from an elliptical to a parabolical one. And I am the more confirmed in my opinion of its being the ſame; for, in the year 1456, in the ſummer-time, a comet was ſeen paſſing retrograde between the earth and the ſun, much after the ſame manner; which, although nobody made obſervations upon it, yet, from its period, and the manner of its tranſit, I cannot think different from thoſe I have juſt now mentioned. And ſince looking over the hiſtories of comets, I find, at an equal interval of time, a comet to have been ſeen about Eaſter, in the year 1305, which is another double period of 151 years before the former. Hence, I think, I may venture to foretel that it will return again in the year 1758." Dr. Halley computed, *lævi calamo*, as he himſelf informs us, the effect of Jupiter upon this comet in 1682, and found that it would increaſe its periodic time above a year, in conſequence of which he predicted its return at the end of the year 1758, or the beginning of 1759. M. Clairaut computed the effects both of Saturn and Jupiter, and found that the former would retard its return in the laſt period 100 days, and the latter 511 days; and he determined the time when the comet would come to its perihelion to be in April 15, 1759, obſerving that he might err a month, from neglecting ſmall quantities in the computation. It paſſed the perihelion on March 13, within 33 days of the time computed. Now if we ſuppoſe the time ſtated by Dr. Halley, to mean the time of its paſſing the perihelion, then if we add to that 100 days, ariſing from the action of Saturn which he did not conſider, it will bring it very near to the time in which it did paſs the perhelion, and prove his computation of the effect of Jupiter to have been very accurate. If he mean the time when it would firſt appear, his prediction was very accurate, for it was firſt ſeen on December the 14th, 1758, and his computation of the effects of Jupiter will then be more accurate than could have been expected, conſidering that he made his calculations only by an indirect method, and in a manner profeſſedly not very accurate. Dr. Halley, therefore, had the glory, firſt to foretel the return of a comet, and the event anſwered remarkably to his prediction. He further obſerved, that the action of Jupiter, in the deſcent of the comet towards its perihelion in 1682, would tend to increaſe the inclination of its orbit; and accordingly the inclination in 1682 was found to be 22′ greater than in 1607. From the obſervations of M. Meſſier upon a comet in 1770, M. Edric Proſperin, member of the Royal Academies of Stockholm and Upſal, ſhewed, that a parabolic orbit would not anſwer to its motions, and he recommended it to aſtronomers to ſeek for the elliptic orbit. This laborious taſk was undertaken by M. Lexell, who has ſhewn that an ellipſe, in which the periodic time is about 5 years and 7 months, agrees very well with the obſervations. (See Phil. Tranſ. for 1779.) As the ellipſes which the comets deſcribe are all very eccentric, aſtronomers, for the eaſe of calculation, ſuppoſe them to move in parabolic orbits for that part which lies within the reach of obſervation, by which they can very accurately find the place of the perihelion of a comet, its diſtance from the ſun, the inclination of the plane of its orbit to the ecliptic, and the place of the node. But before we can determine the orbit of a comet, from obſervation, it will be neceſſary to premiſe ſuch particulars reſpecting the motion of a body in a parabola, as may be requiſite for ſuch an inveſtigation.

Accordingly let A P M (*fig.* 25.) be a parabola, S it's focus, A the vertex, P the place of the body, draw P Q perpendicular to A S, and P D perpendicular to the tangent P T, alſo S M perpendicular to A D. Now, by the property of the parabola, Q D is equal to half the latus rectum; hence if $AS = 1$, then $QD = 2$; alſo the angle P S A $= 2$ P D A; therefore if Q D be radius, P Q will be the tangent of P D A, or $\frac{1}{2}$ P S A; hence to the radius A S, P Q will be twice the tangent of $\frac{1}{2}$ P S A; therefore if $2t = PQ$, t will be the tangent of (z) half the true anomaly P S A, to the radius $AS = 1$. Alſo, by the property of the parabola, $AQ \times 4AS = PQ^2$, hence $AQ = t^2$; alſo the area $AQP = \frac{4}{3}t^3$; and as $QS = 1 - t^2$, the area $QPS = t - t^3$; hence the area $ASP = \frac{1}{3}t^3 + t$; alſo the area $ASM = \frac{4}{3}$. Now let a and b be the times in which the comet moves from A to M, and from A to P; then, as the areas deſcribed about S are proportional to the times, $a : b :: \frac{4}{3} : \frac{1}{3}t^3 + t$, therefore $at^3 + 3at = 4b$.

Hence if a, and the true anomaly be given, we have the time $b = \frac{1}{4}at^3 + \frac{3}{4}at$. Alſo, becauſe $a : b :: \frac{4}{3} : \frac{1}{3}t^3 + t$, therefore if the true anomaly, and conſequently t, be given in different parabolas, the times of deſcribing thoſe true anomalies from the perihelions will be in proportion to the times of deſcribing 90° from the perihelions.

If the times a and b be given, the true anomaly may be found from reſolving the cubic equation $t^3 + 3t = \frac{b}{\frac{1}{4}a}$, which may be done thus. In the right-angled triangle C A B, (*fig.* 26.) let $AB = 1$, $AC = \frac{b}{\frac{1}{4}a}$, and compute B C; then find two mean proportionals between $BC + AC$ and $BC - AC$, and their difference is the value of t.

Take the fluxion of $t^3 + 3t = \frac{4b}{a}$, and we have $\dot{t} = \frac{4}{3a} \times \frac{\dot{b}}{1+t^2}$; but $\dot{t} = \overline{1+t^2} \times \dot{z}$; hence we get $2\dot{z} = \frac{8}{3a} \times \frac{\dot{b}}{\overline{1+t^2}^2} = \frac{8}{3a} \times \overline{\text{coſ. } z}^4 \times \dot{b}$ the variation of the true anomaly correſponding to any ſmall variation $\dot{b}$ of time expreſſed in decimals of a day, a being expreſſed in days.

Let S A (*fig.* 25.) be the mean diſtance of the earth from the ſun; then the area of the circle, deſcribed with that radius, will be 3.14159; alſo the area $AMS = \frac{4}{3}$. Now the velocity in the parabola : velocity in the circle :: $\sqrt{2} : 1$; for let P p (*fig.* 27.) be an indefinitely ſmall arc deſcribed by the body, S the place of the ſun, S N a line drawn from the focus S, perpendicular to a tangent to the parabola A P D at the point P; then, 1ſt, *The velocity* u *in any point* P *of the parabola, is as the ſquare root of the parameter to the axis, divided by* S N: for, the velocity is as the arc P p or $u = p$P: now, pM being perpendicular to P S, in the ſimilar right-angled triangles pP M, P S N, S N : S P :: pM : pP $= \frac{pM \times SP}{SN}$. But the parameter is as the ſquare of the deſcribed ſectors; therefore R (the parameter) $= pM^2 \times SP^2$, and $\sqrt{R} = pM \times SP$; and by ſubſtitution, pP or $u = \frac{\sqrt{R}}{SN}$ or $u = \frac{\sqrt{4AS}}{SN}$, from the nature of the parabola. 2dly, *The velocity* u *in any point* P *of the parabola, is to the velocity* V *of a body running through the circumference of a circle with a central force tending to its centre, the radius being equal to* S P, *as* $\sqrt{2} : 1$. For, ſince $u = \frac{\sqrt{4AS}}{SN}$, $u^2 = \frac{4AS}{SN^2}$; or, becauſe $SN^2 = SP \times SA$ (by the property of the Parabola), $u^2 = \frac{4AS}{SP \times AS} = \frac{4}{SP}$. But the circle whoſe radius is S P, being taken as an ellipſis, its parameter is $= 2$ S P; and the velocity V being uniform, it is every-where as $\frac{\sqrt{2SP}}{SP}$; therefore $VV = \frac{2SP}{SP^2} = \frac{2}{SP}$: conſequently $u^2 : V^2 :: \frac{4}{SP} : \frac{2}{SP} :: 2 : 1$; and therefore $u : V :: \sqrt{2} : \sqrt{1} :: \sqrt{2} : 1$.

The areas deſcribed in the ſame time will be in the ſame ratio as the velocities, becauſe at A the motion in each orbit being perpendicular to S A, the areas deſcribed will be as the velocities, and it being ſo in one caſe, it muſt be always ſo, becauſe in each orbit reſpectively equal areas are deſcribed in equal times. But the times of deſcribing any two areas are as the areas directly, and the areas deſcribed in the ſame time inverſely; therefore $\frac{3.14159}{2} : \frac{4}{3\sqrt{2}} \left(\frac{\sqrt{8}}{3}\right)$ :: the time of the revolution in the circle = 365d. 6h. 9′ : the time of deſcribing A M = 109d. 14h. 46′. 20″. Now as the time of deſcribing A M is in a given ratio to the time in the circle, which varies as $AS^{\frac{3}{2}}$, therefore if r = the perihelion diſtance in any other parabola, we have $1^{\frac{3}{2}} : r^{\frac{3}{2}}$ :: 109d. 14h. 46′. 20″ : the time of deſcribing 90° in that parabola from the perihelion. Hence, knowing the time correſponding to any true anomaly in that parabola whoſe perihelion diſtance = 1, we know the time correſponding to the ſame true anomaly in any other parabola, becauſe the times of deſcribing 90° are as the times correſponding to the ſame true anomaly; therefore if n be the number of days correſponding to any given anomaly in that parabola whoſe perihelion diſtance is unity, then $n r^{\frac{3}{2}}$ will be the time t correſponding to the ſame anomaly in that whoſe perihelion diſtance is r; this may be readily found thus. Multiply the log. r by 3 and divide by 2, and to the quotient add the log. n, and the ſum will be the log. of the time required. Hence alſo $n = \frac{t}{r^{\frac{3}{2}}}$; therefore if from the log. t we ſubtract $\frac{3}{2}$ log. r, it gives the log. n of the number of days correſponding to the ſame anomaly in the parabola, whoſe perihelion diſtance $= 1$; hence the anomaly will be found from a table which exhibits the times correſponding to the true anomaly for 200000 days from the perihelion, in that parabola whoſe perihelion diſtance is unity. This table may be conſtructed by the preceding problem, by taking $a = 109,6154$, and aſſuming $b = 1, 2, 3, 4$, &c. and finding the correſponding values of t. Dr. Halley firſt conſtructed a table of this kind. M. de la Caille changed it into a more convenient form, by putting the areas for the times; Mr. Vince has given that which was computed by M. de Lambre. (See Vince's Aſtron. vol. i. p. 454, &c.)

Draw SY perpendicular to the tangent; then $SP : SY :: SY : SA$, therefore $\sqrt{SP} : \sqrt{SA} :: SP : SY ::$ rad. : coſ. PSY, or $\frac{1}{2}$ PSA the true anomaly; or $SP : SA :: \overline{\text{rad.}}^2 : \overline{\text{coſ. } \frac{1}{2} \text{ true anom.}}^2$ Hence, if $SA = 1$, and $a + x = \frac{1}{2}$ PSA, $a - x = \frac{1}{2}$ pSA, then $1 : \sqrt{SP} ::$ coſ. $\overline{a+x}$: rad. and $\sqrt{Sp} : 1 ::$ rad. : coſ. $\overline{a-x}$; hence $\sqrt{Sp} : \sqrt{SP} ::$ coſ. $\overline{a+x}$: coſ. $\overline{a-x}$.

Hence $SP = \frac{SA}{\overline{\text{coſ. } \frac{1}{2} \text{ true anom.}}^2}$, radius being unity; therefore from log. SA ſubtract twice the log. coſ. $\frac{1}{2}$ true anomaly, and the remainder is the log. of the diſtance of the comet from the ſun.

Erect BD (*fig.* 28.) perpendicular to AB, take $BC = AB$, produce AC to E, and draw EDF perpendicular to AE, meeting AF parallel to BD in F, join AD, and draw DG, CH parallel to AB. Then, as $EAF = 45°$, $EA = EF$; alſo $FG = GD = AB$; hence $AF = BD + BA$, and $GH = BD - BA$; alſo, by ſimilar triangles, AF or $BD + BA : CD = GH$ or $BD - BA ::$ EF or $EA : ED ::$ rad. : tan. DAE; but $AB : BD ::$ rad. : tan. BAD. from which ſubtract 45°, and we have $BD + BA : BD - BA ::$ rad. : tan. of that difference. If $BD = \sqrt{SP}$, and $BA = \sqrt{Sp}$, then $\sqrt{SP} : \sqrt{Sp} ::$ rad. : tan. $BAD = \sqrt{\frac{Sp}{SP}}$; hence, to get that angle, take half the difference of the logarithms of SP and Sp, and add 10 to the index (becauſe in the log. tangents, the index of log. tan. of 45°, or log. of rad. $= 1$, is 10, inſtead of 0,) and it gives the log. tangent of the angle; from which take 45°, and we have $\sqrt{SP} + \sqrt{Sp} : \sqrt{SP} - \sqrt{Sp} ::$ rad. : tang. of that difference.

Hence if we know two radii SP, Sp (*fig.* 25.) and the angle PSp between, we can find the two anomalies. For let a be $\frac{1}{4}$ of ASP + ASp, and x be $\frac{1}{4}$ of ASP − ASp, then $\frac{1}{2}$ ASP $= a + x$, and $\frac{1}{2}$ AS$p = a - x$; hence $\sqrt{Sp} : \sqrt{SP} ::$ coſ. $\overline{a+x}$: coſ. $a - x ::$ (by plane Trig.) coſ. $a \times$ coſ. $x -$ ſin. $a \times$ ſin. x : coſ. $a \times$ coſ. $x +$ ſin. $a \times$ ſin. x, therefore $\sqrt{SP} + \sqrt{Sp} : \sqrt{SP} - \sqrt{Sp} ::$ coſ. $a \times$ coſ. x : ſin. $a \times$ ſin. $x :: \frac{\text{coſ. } a}{\text{ſin. } a} : \frac{\text{ſin. } x}{\text{coſ. } x} ::$ cot. a : tan. x. Now the ratio of the two firſt terms is found from the laſt article, and as the angle PSp is given, the value of x will be given, hence we find a, and conſequently we know the ſum and difference of ASP, ASp, therefore we know the angles themſelves. If p lie on the other ſide of A, then we know a, to find x.

Given two diſtances SP, Sp from the focus to the curve of a parabola, and the angle between them, to find the parabola (*fig.* 29.) With the centres P and p, and radii PS, pS, deſcribe two circular arcs $r w t$, $m v n$, to which draw the tangent $a v w b$; draw ST perpendicular to $a b$, and biſect it in A, and it will be the vertex of the parabola; hence we may deſcribe the parabola.

Having the Elements of the Orbit of a Comet, to compute its place at any time.

The elements of the orbit of a comet are, 1. The time when the comet paſſes the perihelion.—2. The place of the perihelion.—3. The diſtance of the perihelion from the ſun.—4. The place of the aſcending node.—5. The inclination of the orbit to the ecliptic. From theſe elements, the place at any time may be computed; and, for example, we ſhall take that given by M. de la Caille in his Aſtronomy. The comet in 1739, which was retrograde, paſſed its perihelion on June 17, at 10h. 9′ 30″ mean time; the place of the perihelion was in 3^s 12° 38′ 40″; the perihelion diſtance was 0.67358, the mean diſtance of the earth from the ſun being unity; the aſcending node was in 0^s 27° 25′ 14″, and the inclination of the orbit 55° 42′ 44″; to compute the place ſeen from the earth on Auguſt 17, at 14′ 20″ mean time.

Let WAV (*fig.* 30) be the parabolic orbit of the comet, N the aſcending node, P the place of the comet, T the correſponding place of the earth, and draw Pv perpendicular to the ecliptic; produce SN, Sv, SP, ST to n, u, p and t the ſphere of the fixed ſtars, and deſcribe the great circles $n p$, $n u$ ♈ t and $p u$.

I. The interval of time from the perihelion to the given time is 61*d.* 4*h.* 10′ 30″ = 61.174, whoſe log. is 1.786567; alſo the log. of .67358 is 9.828388, $\frac{3}{2}$ of which log. (from the nature of logarithms) is 9.742582, which ſubtracted from 1.786567 leaves 2.043985, the log. of 110.6587 days, which, by the table, anſwers to 3^s 0° 21′ 38″ the true anomaly PSA at the given time.

II. Subtract 3^s 0° 21′ 38″ from 3^s 12° 38′ 40″ the place of the perihelion, becauſe the comet was retrograde, and had paſſed the perihelion, and it leaves 12° 17′ 1″ for the heliocentric place p of the comet in its orbit.

III. The longitude of n is 27° 25′ 14″, alſo $p n =$ 27° 25′ 14″ − 12° 17′ 1″ = 15° 8′ 13″; hence rad. : coſ. $p n u$ = 55° 42′ 44′ :: tan. $p n$ = 15° 8′ 13″ : tan. $u n$ = 8° 39′ 53″ the diſtance of the comet from the aſcending node, meaſured upon the ecliptic.

IV. Subtract this value of $u n$ from the place of the node, and there remains 18° 45′ 21″ = ♈ u the true heliocentric place of the comet reduced to the ecliptic.

V. As rad. : ſin. $p n$ = 15° 8′ 13″ :: ſin. $p n u$ = 55° 42′ 44″ : ſin. $p u$ = 12° 27′ 34″ the latitude ſeen from the ſun, which is ſouth.

VI. The true place T of the earth at the ſame time is 10^s 24° 34′ 36″; hence TS♈ = 35° 25′ 24″; therefore TS♈ + ♈Su = TSv = 1^s 24° 10′ 45″. Alſo TS = 1.0115.

VII. By a preceding article, $\overline{\text{coſ. } 45° \, 10' \, 49''}^2 : \overline{\text{rad.}}^2 :: .67358 : SP = 1.3557$.

VIII. As rad. : coſ. $PSv = 12° \, 27' \, 34'' :: SP = 1.3557 : Sv = 1.32377$.

IX. In the triangle TSv, we know TS, Sv and the included angle TSv; hence, by plain trignometry, we find the angle $STv = 77° \, 33' \, 38'' \frac{1}{2}$, which ſubtracted from $4^s \, 24° \, 34' \, 36''$, the place of the ſun, leaves $2^s \, 7° \, 0' \, 57'' \frac{1}{2}$ for the comet's true *geocentric longitude.*

X. Moreover, as ſin. $54° \, 10' \, 45''$: ſin. $77° \, 33' \, 38'' \frac{1}{2}$ :: tan. $PSv = 12° \, 27' \, 34''$: tan. $PTv = 14° \, 54' \, 4''$ the comet's true *geocentric latitude.*

To determine the Orbit of a Comet from Obſervation.

Sir I. Newton firſt reſolved this problem, which he called *Problema longe difficillimum.* The orbit of a comet may be computed from three obſervations; but although theſe data be ſufficient, the direct ſolution of the problem is impracticable. Aſtronomers therefore have ſolved this problem by indirect methods, firſt finding an orbit very near to the truth by mechanical and graphical operations, and then, by computation, correcting it, until ſuch a parabola was found as would ſatisfy the obſervations. Mr. Vince therefore begins, by ſhewing the methods by which the orbit may be nearly determined; and then explains the manner in which it may be corrected by calculation.

M. de la Lande propoſes the following mechanical method of finding the orbit nearly. Divide the diſtance of the earth from the ſun into ten equal parts, and deſcribe ten parabolas whoſe perihelion diſtances are, 1, 2, 3, &c. of theſe parts, and divide theſe parabolas into days from the perihelion, anſwering to the motion of a body in each. Let S (*fig.* 31.) be the ſun, *a*, *b*, *c*, the places of the earth at the times of three obſervations of the comet. Then take three geocentric latitudes and longitudes of the comet, and ſet off the elongations $S a \alpha$, $S b \beta$, $S c \gamma$, in longitude. From *a*, *b*, *c*, extend three fine threads *am*, *bn*, *ep*, vertical to $a\alpha$, $b\beta$, $c\gamma$, making angles with them equal to the geocentric latitudes reſpectively. Then take any one of the parabolas, and placing its focus in S apply the edge to the threads, and obſerve whether you can make it touch them all, and whether the intervals of time cut off by the threads upon the parabola be equal to the reſpective intervals of the obſervations, or very nearly ſo; and if theſe circumſtances take place, you have then gotten the true parabola, or very nearly the true one. But if the parabola do not agree, try others, till you find one which does agree, or very nearly ſo, and you will then have got very nearly the true parabola, whoſe inclination, place of the node, and perihelion, are to be determined as accurately as poſſible from menſuration; alſo the projection upon the ecliptic. If none of theſe parabolas ſhould nearly anſwer, it ſhows, that the perihelion diſtance muſt be greater than the diſtance of the earth from the ſun, in which caſe, other parabolas muſt be conſtructed; but this does not very often happen. This method will determine the elements very nearly; but it would be extremely troubleſome to conſtruct and divide ſo many parabolas, if we only wanted to compute the elements of one comet; for thoſe who purpoſe to make many computations of this kind, it might be worth while to have a ſet of parabolas thus divided. To avoid this trouble therefore, Mr. Vince propoſes to do it in the following manner, by means of one parabola, without dividing it.

Take a firm board perfectly plane, and fix on paper for the projection; let a groove be cut near the edge, and five perpendiculars be moveable in it, ſo that they may be fixed at any diſtances. Let S (*fig.* 32.) repreſent the ſun, and deſcribe any number of circles about it. Compute five geocentric latitudes and longitudes of the comet, from which you will have the five elongations of the comet at the times of the reſpective obſervations. Draw SA, SB, SC, SD, SE, making the angles ASB, BSC, CSD, DSE, equal to the ſun's motion in the intervals of the obſervations; and on any one of the circles, make the angles $S a \alpha$, $S b \beta$, $S c \gamma$, $S d \delta$, $S e \varepsilon$, equal to the reſpective elongations in longitude, and fix the five perpendiculars, ſo that the edge of each may coincide with α, β, γ, δ, ε. From the points *a*, *b*, *c*, *d*, *e*, extend threads to the reſpective perpendiculars, making angles with the plane equal to the geocentric latitudes of the comet; then fix the focus of the parabola in S, and apply its edge to the threads, and if it can be made to touch them all, it will be the parabola required, correſponding to the mean diſtance S *a* of the earth, which we here ſuppoſe to revolve in a circle, as it will be ſufficiently accurate for our purpoſe. If the parabola cannot be made to touch all the threads, change the points *a*, *b*, *c*, *d*, *e*, to ſuch of the other circles as you may judge, from your preſent trial, will be moſt likely to ſucceed, and try again; and by a few repetitions you will get ſuch a diſtance for the earth, that the parabola ſhall touch all the threads, in which poſition, find the inclination, obſerve the place of the node, and meaſure the perihelion diſtance, compared with the earth's diſtance, and you will get very nearly the elements of the orbit.

The next method of approximating to the orbit of a comet, which we ſhall explain, is that given by Boſcovich. Let S (*fig.* 33.) be the ſun, XZ the orbit of the earth, ſuppoſed to be a circle; T the place of the earth at the firſt obſervation, and *t* at the third; draw TC, *tc* to repreſent the obſerved longitudes of the comet; and let L, *l*, λ be the longitudes at the firſt, ſecond, and third obſervations; *m* and *n* the geocentric latitudes of the comet at the firſt and third obſervations; and *t*, T, the intervals of time between the firſt and ſecond, ſecond and third obſervations. Aſſume C for the place of the comet, at the firſt obſervation, reduced to the ecliptic; then to determine the point at the third obſervation, ſay $T \times \text{ſin.} \, \overline{\lambda - l} : t \times \text{ſin.} \, \overline{l - L} :: TC : tc$, and *c* will be nearly the place required; (See Boſcov. "Opuſcula," vol. iii. or ſir H. Englefield's valuable work upon comets, p. 27.) join C*c*, and it will repreſent the path of the comet on the ecliptic, upon this aſſumption. Perpendicular to the ecliptic draw CK, *ck*, taking CK : TC :: tan. *m* : radius, and *ck* : *tc* :: tan. *n* : radius; join K*k*, and it will repreſent the orbit of the comet, if the firſt aſſumption be true. Biſect C*c* in *x*, and draw *xy* parallel to CK, and *y* will biſect K*k*; join *y*S. Let SX = 1; then if *v* be the mean velocity of the earth in its orbit, the velocity of the comet at $y = \frac{\sqrt{2} \times v}{\sqrt{Sy}}$; taking therefore $v = Tt$, compute $\frac{\sqrt{2} \times v}{\sqrt{Sy}}$, and if this be equal to K*k*, meaſured by the ſcale, the aſſumed point C was the true point. But if theſe quantities be not equal, aſſume a new point for C, in doing which, the error of the firſt aſſumption will direct you which way, from the firſt aſſumed point, it muſt be taken, and about how far from it; if, for inſtance, the computed value of K*k* be greater than the true value, and the lines CK, *ck*, are diverging from each other, and receding from the ſun, the point C muſt be taken further from T, and how much further we muſt conjecture from the value of the error, and alſo from hence, that the velocity of the comet diminiſhes as it recedes from the ſun. Theſe conſiderations will lead us to make a ſecond aſſumption near to the truth. Having thus determined the true points C, *c*, very nearly, produce *c* C, *k* K to meet at N, join N S, and it will be the line of the nodes. Draw C *r*, *c z* perpendicular to S N, and the angles K *r* C, *k z c* will meaſure the inclination of the orbit. From the two diſtances S C, S *c*, and the angle between, the parabola may be conſtructed, and applied as in the laſt method, from which the time of paſſing the perihelion may be found.

Another method by which we may readily get the orbit very nearly, is this. Let S (*fig.* 34.) be the ſun, T, *t*, *τ* three places of the earth at the times of the three obſervations; extend three threads T *p*, *t n*, *τ m*, in the directions of the comet, as before directed. Aſſume a point *y* for the place of the comet at the ſecond obſervation, and meaſure S *y*; then if S T = 1, and the velocity of the earth be *v*, the velocity of the comet at *y* will be $\frac{\sqrt{2} \times v}{\sqrt{Sy}}$; let *v* be repreſented by T *t*, *t τ*; and upon any ſtraight edge P Q, ſet off $ce = \frac{\sqrt{2} \times Tt}{\sqrt{Sy}}$, and $ed = \frac{\sqrt{2} \times t\tau}{\sqrt{Sy}}$; then apply the point *e* to *y*, and, by turning about the edge, try whether you can make the point *c* fall in T *p*, and the point *d* in *τ m*; if you find this can not be done, the error will direct you to aſſume another diſtance; and by a very few trials you will find the point *y* where the points *c* and *d* will fall in T *p*, *τ m*. This method is very eaſy in practice, and ſufficiently accurate to obtain a diſtance S *y*, from which you may begin to compute, in order to find the orbit more correctly, when the comet is not too near to the ſun, as, ſays Mr. Vince, I have found by experience.

Having determined the parabola nearly, we firſt aſſume ſome one quantity as known at the firſt and ſecond obſervations, and thence compute the place of the comet at thoſe times, and alſo the time between; and if that time agree with the obſerved interval, you have got a parabola which agrees with the two firſt obſervations; if the times do not agree, alter one of the aſſumed quantities, and ſee how it then agrees; and then, by the rule of falſe, you may correct the ſuppoſition which was altered, and get a parabola which will agree with the two firſt obſervations. In like manner, by altering the other aſſumed quantity, you get another parabola agreeing with the two firſt obſervations. Then ſee how they agree with the third obſervation, and if they do not, a correction muſt be made by proportion, and the three obſervations will be anſwered.

For further particulars we muſt refer to Vince's Aſtronomy, vol. i. p. 428, &c. See alſo "An account of the diſcoveries concerning comets, with the way to find their orbits, and ſome improvements in conſtructing and calculating their places, to which are added new tables, fitted for theſe purpoſes;" by Thomas Barker, Gent. Lond. 1757.

As the comets do not move in parabolas, but in very eccentric ellipſes, it is impoſſible to find a parabola agreeing accurately to all the *data;* it will be ſufficient, therefore, when it agrees very nearly. When great accuracy is required, we muſt take into conſideration the effect of aberration and parallax; the former may be computed in the manner ſtated under the article Aberration, and the latter by taking the horizontal parallax to that of the ſun = 8″,75 as the diſtance of the ſun is to the diſtance of the comet; and then finding the parallax in latitude and longitude.

To aſcertain the periodical time of a Comet, and the axes of its Orbit.

If comets, after having receded from the lower regions of the ſolar ſyſtem to vaſt diſtances beyond the orbits of the moſt diſtant planets return again to the neighbourhood of the ſun, the paths they deſcribe muſt be nearly elliptical; and then, if obſervations have been made ſufficiently exact to be a baſis of the operations, the requiſites of the problem may be determined in the following manner: Let A K B I (*fig.* 35.) be the trajectory of a comet, A B its major axis, I K the minor, S, F, the two foci, the former of which being the place of the ſun, C the place of the comet, C S its diſtance from the ſun, C *c* the ſpace it paſſes over in a very ſmall portion of time, D C E a tangent to the curve in the point C, S D, F E, perpendiculars demitted thereon from the foci: draw S G parallel to the tangent, and join F C. Alſo, let A L B be a circle, deſcribed on the major axis A B; A P T B a rectangle about the ellipſis A I B, and A Q R B a ſquare about the circle A L B. Laſtly, let A N O be the elliptic orbit of any planet, S, *f*, its foci; put S C = *a*, S D = *b*, C *c* = *e*, the time in which it is deſcribed *f*, the major axis of the cometary orbit A B = *x*, of the planetary orbit A O = *q*, the circumference of the circle A V O deſcribed on the ſame axis = *p*, the periodical time of the comet = *t*, and that of the planet = *n*.

The ſpace C *c* deſcribed, the diſtance S C, and the angle S C D, being all determinable by obſervation, are given quantities. The mean diſtance of the comet is A H = S K $= \frac{1}{2}x$, and of the planet is A *g* = S N $= \frac{1}{2}q$; and, becauſe the ſquares of the periodical times are as the cubes of the mean diſtances, we have $\frac{1}{8}q^3 : \frac{1}{8}x^3 :: n^2 : t^2$; therefore $t^2 = \frac{\frac{1}{8}x^3n^2}{\frac{1}{8}q^3}$, and $t = \frac{nx}{q}\sqrt{\frac{x}{q}}$.

But it is neceſſary to find another expreſſion for the periodical time *t*, which may be done thus: becauſe C *c* is a very minute portion of the orbit, it may be eſteemed a right line, and the ſector C S *c* as a rectilineal triangle, whoſe area $\frac{1}{2}$ S D × C *c* $= \frac{1}{2}be$ is given: then, as the area $\frac{1}{2}be$, is to the whole area of the ellipſis A K B I = A; ſo is the time *f*, to the whole periodical time *t*; wherefore $t = \frac{f}{\frac{1}{2}be} \times A$.

Now, in order to determine the area A, we muſt find the ſemiconjugate H K; and here, becauſe A B = S C + F C, we have F C $= x - a$; and by the ſimilar triangles S D C, F E C, we have S C : S D :: F C : F E, that is, $a : b :: x - a : \frac{bx - ab}{a} = FE$; conſequently $FG = FE - GE = \frac{bx - 2ab}{a}$. Again, S C : C D :: F C : C E; or $a : \sqrt{a^2 - b^2} :: x - a : \frac{x - a}{a}\sqrt{a^2 - b^2}$: hence D E or $SG = CE + CD = \frac{x - a}{a}\sqrt{a^2 - b^2} + \sqrt{a^2 - b^2} = \frac{x}{a}\sqrt{a^2 - b^2}$. But $FG = \frac{bx - 2ab}{a}$; therefore $FS = \sqrt{FG^2 + SG^2} = \sqrt{\frac{b^2x^2 - 4ab^2x + 4a^2b^2 + a^2x^2 - b^2x^2}{a^2}} = \sqrt{\frac{a^2x^2 - 4ab^2x + 4a^2b^2}{a^2}}$; and, of courſe, $SH = \frac{1}{2}FS = \sqrt{\frac{a^2x^2 - 4ab^2x + 4a^2b^2}{4a^2}}$.

Moreover, ſince S K = A H $= \frac{1}{2}x$, $HK = \sqrt{SK^2 - SH^2} = \sqrt{\frac{1}{4}x^2 - \frac{a^2x^2 - 4ab^2x + 4a^2b^2}{4a^2}} = \frac{b}{a}\sqrt{ax - a^2}$; therefore $IK = 2\,HK = \frac{2b}{a}\sqrt{ax - a^2}$,

$\sqrt{a x - a^2}$, and $\frac{x b}{a} \sqrt{a x - a^2}$ = area of the rectangle A P T B. Let P be the periphery of the circle A L B, whoſe diameter is x, then its area will be $\frac{1}{2}$ L H × P = $\frac{1}{4} x$ P, and we ſhall have $x^2 : \frac{1}{4} x$ P :: $\frac{1}{2} x^2 : \frac{1}{8} x$ P :: A Q R B : A L B :: A P T B : A I B :: $q^2 : \frac{1}{4} q p$; that is $q^2 : \frac{1}{4} q p$ :: $\frac{x b}{a} \sqrt{a x - a^2} : \frac{b p x}{4 a q} \sqrt{a x - a^2}$ = A I B. But 2 A I B = A I K B = A = $\frac{b p x}{2 a q} \sqrt{a x - a^2}$: therefore, ſubſtituting this value of A, in the preceding expreſſion, we have $t = \frac{f p x}{a e q} \sqrt{a x - a^2}$. Equate this value of t, with that already given, then $\frac{n x}{q} \sqrt{\frac{x}{q}} = \frac{f p x}{a e q} \sqrt{a x - a^2}$; which equation reduced, gives $x = \frac{a f^2 p^2 q}{f^2 p^2 q - a e^2 n^2}$ = A B, the major axis of the comet's elliptical trajectory.

If we ſubſtitute this value of x, in the above equation, for t, we ſhall have $t = \frac{p^3 f^3 n^2 a^{\frac{3}{2}}}{\overline{q f^2 p^2 - a e^2 n^2}|^{\frac{3}{2}}}$ = the periodical time. Alſo, becauſe the conjugate I K $= \frac{2 b}{a} \sqrt{a x - a^2} = c$, we have $x = \frac{c^2 a^2 + 4 b^2 a^2}{4 b^2 a} = \frac{a f^2 p^2 q}{f^2 p^2 q - a e^2 n^2}$, whence by reduction, we find $c = 2 b e n \sqrt{\frac{a}{f^2 p^2 q - a e^2 n^2}}$, the minor axis of the orbit.

From theſe equations, it obviouſly appears, that when the velocity of the comet is ſuch that $f^2 p^2 q = a e^2 n^2$, the axis x will be infinite, and conſequently the trajectory will be a parabola; if $a e^2 n^2$ be greater than $f^2 p^2 q$, the direction of the axis will be on the other ſide of the curve, which will be an hyperbola; in either of which caſes, the comet can never return: but in every inſtance where $f^2 p^2 q$ is greater than $a e^2 n^2$, the comet will deſcribe an ellipſis; among theſe we may compriſe the circle, where $x = 2 a = \frac{a f^2 p^2 q}{f^2 p^2 q - a e^2 n^2}$ and $f^2 p^2 q = 2 a e^2 n^2$, whence e = C $c = \frac{f p}{a} \sqrt{\frac{q}{2 a}}$, the arc of the circle deſcribed in one day, or one hour, according as the value of n is given in days, or hours.

Let the earth be the planet which we ſuppoſed to deſcribe the ellipſis A N O; then its mean diſtance $\frac{1}{2} q = 100000$, or $q = 200000$, and $p = 628318$; alſo the periodical time n = one year: then if C c be the portion of the comet's orbit deſcribed in one day, we have $f = \frac{1}{365.2565} = 0.0027378$. The other expreſſions will become as follow: for the principal axis, $x = \frac{5918.6599235 \times a}{5918.6599235 - a e^2}$, and for the periodical time $t = \frac{4750560000 \times a^{\frac{3}{2}}}{\overline{59\text{[illegible]}35 - a e^2}|^{\frac{3}{2}}}$.

It is extremely difficult to determine, from computation, the elliptic orbit of a comet, to any degree of accuracy; for when the orbit is very eccentric, a very ſmall error in the obſervation will change the computed orbit into a parabola, or hyperbola. Now, from the thickneſs and inequality of the atmoſphere with which the comet is ſurrounded, it is impoſſible to determine, with any great preciſion, when either the limb or centre of the comet paſs the wire at the time of obſervation. And this uncertainty in the obſervations will ſubject the computed orbit to a great error. Hence it happened, that M. Bouguer determined the orbit of the comet in 1729 to be an hyperbola. M. Euler firſt determined the ſame for the comet in 1744; but having received more accurate obſervations, he found it to be an ellipſe. The period of the comet in 1680 appears, from obſervation, to be 575 years, which M. Euler, by his computation, determined to be 166½ years. The only ſafe way to get the period of comets, is to compare the elements of all thoſe which have been computed, and where you find they agree very well, you may conclude that they are elements of the *ſame* comet, it being ſo extremely improbable that the orbits of two different comets ſhould have the ſame inclination, the ſame perihelion diſtance, and the places of the perihelion and node the ſame. Thus, knowing the periodic time, we get the major axis of the ellipſe; and the perihelion diſtance being known, the minor axis will be known. When the elements of the orbits agree, the comets may be the ſame, although the periodic times ſhould vary a little; as that may ariſe from the attraction of the bodies in our ſyſtem, and which may alſo alter all the other elements a little. We have already obſerved, that the comet which appeared in 1759, had its periodic time increaſed conſiderably by the attraction of Jupiter and Saturn. This comet was ſeen in 1682, 1607, and 1531, all the elements agreeing, except a little variation of the periodic time. Dr. Halley ſuſpected the comet in 1680, to have been the ſame which appeared in 1106, 531, and 44 years before Chriſt, when Julius Cæſar was murdered; and that its period was five hundred and ſeventy-five years. Mr. Dunthorne, however, in the Phil. Tranſ. vol. xlvii., has endeavoured to ſhew from a MS. in Pembroke-hall library, that the comet of 1106 could not be the ſame with that of 1680. But M. de la Lande adopts the opinion of Dr. Halley. He alſo conjectured, in the firſt edition of his Synopſis, without repeating it in the ſecond edition, that the comet obſerved by Apian in 1532, was the ſame as that obſerved by Hevelius in 1661; if ſo, it ought to have returned in 1789, or 1790, but it has never been obſerved. The interval between the paſſages of the comet by the perihelion in 1532 and 1661 is 128 years, 89 days, 1 hour, 29 minutes, (32 of the years being biſſextile) which, added to the time of the perihelion in 1661, together with 11 days to reduce it from the Julian to the Gregorian ſtile, which we now uſe, brings out the time of the next perihelion, to be April 27th, 1ʰ 20′, in the year 1789. But M. Mechain having collected all the obſervations in 1532, and calculated the orbit again, found it to be ſenſibly different from that determined by Dr. Halley, which renders it very doubtful whether this was the comet which appeared in 1661; and this doubt is increaſed, by its not appearing in 1790. The comet in 1770, whoſe periodic time M. Lexell computed to be five years and ſeven months, has not been obſerved ſince. There can be no doubt but that the path of this comet, for the time it was obſerved, belonged to an orbit whoſe periodic time was that found by M. Lexell, as the computations for ſuch an orbit agreed ſo very well with the obſervations. But the revolution was probably longer before 1770: for as the comet paſſed very near to Jupiter in 1767, its periodic time might be ſenſibly increaſed by the action of that planet; and as it has not been obſerved ſince, we may conjecture, with M. Lexell, that having paſſed in 1772 again into the ſphere of ſenſible attraction of Jupiter, a new diſturbing force might probably take place and deſtroy the effect of the other. According to the above elements, the comet would be in conjunction with Jupiter on

Auguſt 23, 1779, and its diſtance from Jupiter would be only $\frac{1}{491}$ of its diſtance from the ſun, conſequently the ſun's action would be only $\frac{1}{224}$ times that of Jupiter. What a change muſt this make in the orbit! If the comet returned to its perihelion in March 1776, it would then not be viſible. See M. Lexell's account in the Phil. Tranſ. 1779. The elements of the orbits of the comets in 1264 and 1556 were ſo nearly the ſame, that it is very probable it was the ſame comet; if ſo, it ought to appear again about the year 1848.

Mr. Cole, in his "Theory of Comets," advances an hypotheſis, which, in ſome caſes, may perhaps, be accurate. He ſuppoſes that the orbit of a comet is not an ellipſe; but that, when it paſſes its perihelion, it has acquired ſo great a velocity, that its centripetal force is overcome by its centrifugal, and that conſequently the comet continues to fly off in a parabola or hyperbola, till it come within the attraction of ſome fixed ſtar; that this attraction may give it a new direction, and increaſe its velocity till it come to an apſis below that ſtar, when it may again fly off either in a parabola or hyperbola, and proceed till it fall within the attraction of another ſtar; and thus viſit many different ſyſtems.

Dr. Halley has given us a table of the aſtronomical elements of twenty-four comets, on the ſuppoſition that they moved in parabolas; though he thought it extremely probable that they really moved in very eccentric ellipſes, and conſequently returned after long periods of time. This table commences with the year 1337, and cloſes with 1698. By means of this table, and others ſimilar to it, it may be determined whenever a new comet ſhall appear, by comparing it therewith, whether it be one of thoſe which have already appeared, and conſequently its period and the axis of its orbit be aſcertained, and its return foretold. See his Synopſis of the Aſtronomy of Comets, annexed to Gregory's Aſtronomy. This was firſt publiſhed in the Philoſophical Tranſactions in 1705, and republiſhed with his Aſtronomical Tables in 1749. M. de la Caille changed this table into another of a more convenient form, by putting the areas for the times.

Another table has ſince been computed, from the obſervations contained in the Philoſophical Tranſactions, De la Caille's Aſtronomy, and De la Lande's Hiſtoire de la Comete de 1759, and Connoiſſance des Movemens Celeſtes 1762 & 1764. In this table are ſeen the elements of twenty-five other comets, from the year 1264 to 1762. The moſt extenſive table for calculating the motions of comets, was computed by M. de Lambre; it is inſerted, as we have already mentioned, in Mr. Vince's Aſtronomy, vol. i. Another table on an extenſive ſcale, computed by Mr. Lee, an ingenious friend of the editor, an excellent aſtronomer, and an attentive obſerver of the heavens, is annexed to this article.

The number of comets that are ſtated in the moſt accurate accounts to have appeared, ſince the commencement of our æra, is about 500; and before that æra, about 100 others are recorded to have been ſeen, though it is probable that not more than half of them were comets.

The elements of the comet of 1770, and the trajectory of its path, may be found in the Tranſactions of the American Philoſophical Society, vol. i.

In Whiſton's Solar Syſtem, the orbits of ſeveral comets are delineated, and the periods of as many of them as were then known, expreſſed.

COMET, *To determine the place and courſe of a.* For this purpoſe, it will be adviſable to take the apparent diameter very frequently; as a judgment may thus be formed of its relative diſtance at different times; its degree of motion, its brightneſs, &c. muſt alſo be regarded; for when it moves with the greateſt velocity, or appears moſt bright, we may infer that it is near its perihelion. If the place of the comet can be obſerved when it has no latitude, the place and time of its being in one of its nodes will then be exactly known; but as this can ſeldom be actually obſerved, theſe elements are generally obtained by approximation from other obſervations. In order to obtain the proper courſe of a comet, obſerve its diſtance from two fixed ſtars, whoſe longitudes and latitudes are known: or, find its altitude when in the ſame azimuth with any two known fixed ſtars; from the diſtance or altitude thus found, calculate the place of the comet by trigonometry, after the manner delivered under PLANET, or in the preceding article. By repeating the obſervations and operations for ſeveral days ſucceſſively, the courſe of the comet will be had.

COMET, *to determine the courſe of a, mechanically, and without any apparatus of inſtruments.* The following ingenious method, by a thread, we owe to Longomontanus: Obſerve four ſtars round the comet, ſuch, as that the comet may be in the interſection of the right lines that join the two oppoſite ſtars; which is eaſily found by means of a thread placed before the eye, and extended over-againſt the ſtars and comet.

Suppoſe, v. gr. the comet's place in the heavens A (*Pl.* IV. *Aſtronomy, fig.* 36.) between the four ſtars, B, C, D, E; where the line joining the ſtars B and D, paſſes through the body of the comet; and the like does the line paſſing through C and E.

On a globe, whereon theſe four ſtars are found, extend a thread through B and D, and another through C and E; the point of interſection will give the place of the comet. This practice being repeated for ſeveral days, the comet's courſe will be had on the globe; which courſe will be found to be a great circle: if this great circle, drawn through three diſtant places, and ſhewing its path among the ſtars, be continued till it interſect the ecliptic, it will ſhew nearly the place of the node, and the inclination of the orbit to the ecliptic. The plane of the node and inclination of the orbit being thus found from ſeveral triplets of places independent of each other, a medium of the reſults may be conſidered as tolerably accurate.

COMET, *to determine the parallax of a.* See PARALLAX.

COMET, *trajectory of a.* See TRAJECTORY.

On the ſubject of *Comets*, ſee Newton's Principia, lib. iii. Halley's Synopſis of Comets; Sejour Eſſai ſur les Cometes, 1775; M. Pingre's Cometographie, 2 vols. 4to. 1781, Sir H. Englefield's work "On the determination of the Orbits of Comets;" M. Bode's General Conſiderations on the ſituations of the Orbits of all the Planets and Comets which have hitherto been calculated, inſerted in the Memoirs of the Academy of Sciences of Berlin; Dr. Gregory's Aſtronomy; O. Gregory's Treatiſe on Aſtronomy, 1803; De la Lande, Theorie des Cometes, 1759; and Aſtronomie, vol. iii.; An Account of the Diſcoveries concerning Comets, with the way to find their Orbits, &c. by Thomas Barker, 1757; Vince's Aſtronomy, &c. &c.

COMETARIUM, or Cometarian, in *Mechanics*, is the name of a machine, contrived by Dr. Deſaguliers, for the purpoſe of exhibiting and explaining the eccentric motion of a comet, agreeably to that law, of planetary motion, by which equal areas are deſcribed by the radius vector in equal times. Ben. Martin has given an account of this machine, in his "Young Gentleman and Lady's Philoſophy," and Mr. Ferguſon has deſcribed it ſtill more particularly in his "Aſtronomy," but as thoſe authors have not given a perſpective view of the parts of action, we have thought it neceſſary to give a new drawing, ſuch as we conceive will render the mechaniſm clearly intelligible to every reader. In *Plate* I. of *Planetary Machines*, *fig.* 1. repreſents the cover of the cometarium, taken from the box which contains the wheel-work, and *fig.* 2. ſhews the box and its contents, with the exception of the cover, and one ſide, the latter of which is ſuppoſed to be removed, in order to diſcloſe more fully the diſpoſition of all the contained parts. A B in *fig.* 2. is the bottom of the box, which ſupports the lower pivots of the three vertical arbors; C D is a longitudinal bar inſerted into the ends of the box, and bearing the upper pivots of the ſaid arbors, as may be clearly ſeen in the figure; E is the handle put on the end of the horizontal arbor E F, which arbor is pivoted into the front and back ſides of the box; on this horizontal arbor, under the letter C, is an endleſs ſcrew actuating the wheel G, with teeth not rounded but cut a little obliquely; the number of which teeth may be aſſumed at option, to correſpond to an aliquot part of a circle, ſuppoſe 72, in which caſe one tooth, or revolution of the handle, will correſpond to 5°; at the inferior end of the arbor of wheel G, is fixed another wheel H, of the ſame number of teeth, that actuates a ſimilar wheel I, on the ſecond vertical arbor; ſo that theſe two wheels, H and I, alſo revolve each in $\frac{1}{72}$d part of a circle, or 5°, at each revolution of the handle. Mr. Ferguſon has placed the endleſs ſcrew as in *fig.* 2. of *Plate* II., between the wheels H and I in ſuch a way, as to impel them both in contrary directions at the ſame time, which conſtruction is ſtill more ſimple, as it diſpenſes altogether with the wheel G, and requires no rounding of the teeth; to the arbor of wheel I a ſolid plate K, in the form of an ellipſe, is fixed faſt at a point out of the centre, and has a groove round its edge to admit a cord to paſs round it; and a ſecond elliptic plate L, every way ſimilar to plate K, is attached, at a point equally diſtant from the centre, to the third vertical arbor, but in ſuch a way, that, when an endleſs cord is made to embrace the grooves of both, after croſſing between them, the long radius of one is always directed towards the ſhort radius of the other reciprocally, ſo that as the radius of plate K continues to lengthen in revolving half round, the radius of L continues to ſhorten, and *vice verſâ* during the other half of the revolution; this alteration of gradual lengthening and ſhortening of the radii, of the equably moving elliptic plate K, produces an alternate acceleration and retardation of motion in the plate L, ſuch as correſponds with the equated motion of a heavenly body, deſcribing equal areas in equal times; and the quantity of eccentricity given to the elliptic plates determines the quantum of the greateſt equation in the orbit to be repreſented. Above the croſs-bar CD is fixed an elliptic plate M, by two ſcrews, ſeen in both the figures, round which the comet O is confined to move in its motion round N, the ſun, which is a ball attached to the ſuperior end of the arbor of the plate L of unequable motion; to the ball N, the arm or radius vector N O is attached, which therefore alſo moves with alternate accelerations and retardations of motion along with plate L; and as the comet O has liberty to ſlide along the radius vector, while a ſtud under it penetrates the black elliptic groove, made in the cover round the plate M, the variation of diſtances is thereby effected as the comet is carried round: the point of the greateſt diſtance, where the motion is ſloweſt, is called the *aphelion*, from απο, *from*, and ἡλιον, the *ſun*, and the point of neareſt diſtance, where the motion is quickeſt, is called the *perihelion*, from περι, *round*, and ἡλιον, the *ſun*. The two circles of ſigns, and alſo the graduated ellipſe, are marked on the cover of the machine, and the arm G, in *fig.* 1, is placed on the equably moving arbor of wheel G, in *fig.* 2, ſo that when the arm G moves through the ſigns in the ſmall circle, by equal arcs in equal times, the arm N O moveable round the point N, paſſes through correſponding unequal arcs in the larger circle of ſigns, while the difference between the places of the two ſaid arms ſhews the quantity of proſthaphæreſis, or equation in any ſituation in the large graduated circle, which is aſſumed to be parallel to the comet's orbit. In order that the nature of the comet's motion may be the more apparent to the eye of a ſpectator, when referred to its own orbit, the ſmall ellipſe, beyond the darkened aperture that regulates the diſtances, is alſo divided into ſigns, but in ſuch a way, that the angles ſubtended by each ſign, when referred to the point N, or centre of motion, are unequal among themſelves throughout each ſix ſucceſſive ſigns, and if lines were drawn from each point where the comet is found at the end of each day or week, to the point N, they would include equal areas, or plane ſurfaces taken geometrically; in ſome of the machines indeed, thoſe lines are actually drawn, and the ſeparate triangular areas correſponding to each equidiſtant period are painted alternately black and white, to render the doctrine of the celebrated Kepler ſtill more evident to the ſenſes. The principal objections to the conſtruction of the machine before us is, that the comet O is apt to move by jerks in certain parts of the orbit, particularly when the eccentricity is great; and alſo the cord is liable to ſlide in ſome ſituations, without producing the correſponding motion in the elliptic plates K and L; the latter of which objections has been attempted to be obviated, by attaching forked pieces of metal to the plane of one of the elliptic plates near its end, and pins to the other, as in *fig.* 2. *Plate* II. to form a kind of teeth; but a better plan, and which has been adopted ſometimes in practice, where the eccentricity is not very great, is to cut the elliptic plates themſelves into toothed wheels, and to ſubſtitute them for the wheels H and I, in which caſe the cord may be diſpenſed with altogether, and the arm N O, we preſume, will thus be leſs liable to jerks.—After all, however, this machine does not profeſs to repreſent the period of a revolution of any of the comets or planetary bodies, but is intended merely to explain the law of their motion, which it will do in a very ſatisfactory manner, when well made; and it is eaſy to ſee, that, as the plate M may be fixed more or leſs out of the centre, ſuch a change of diſtances may be produced, as ſhall correſpond to the changes of angular velocity; which is the chief difficulty to be overcome in the mechanical repreſentation of the orbit.

New Cometarium by Mr. Jones.

Subſequently to our writing the preceding account of the cometarium, Mr. W. Jones, optician in Holborn, has favoured us with a drawing and deſcription of a new conſtruction of the cometarium, which he ſays is free from the jerks that we have ſtated as an objection to the plan of Dr. Deſaguliers, and which, therefore, we lay before the public as nearly in the author's own words as our arrangement and obſervations on it will admit.

Fig. 1. of *Plate* II. of *Planetary Machines* is a repreſentation of the external part of the machine, which is not confined to any particular dimenſions, but has generally been made as follows; *viz.* A B C D is a mahogany box, about 12 inches long, 9 wide, and 4½ deep, containing the wheelwork that gives motion to the comet *x*; the dark elliptical ſpace is a groove repreſenting the orbit of the comet, which is carried round in the direction of the alphabetical order of the letters. The point *a* is the perihelion, and the point *g* the aphelion; and the triangular ſpaces or areas, *a* S *b*, *b* S *c*, &c. are all reſpectively equal to each other: in one turn of the handle N, the comet *x* is moved over one of theſe areas; conſequently, in the ſame time that it moves from *f* to *g*, or from *g* to *h*, it moves from *m* to *a*, or from *a* to *b*, and in like manner through each ſucceeding area, the quickeſt motion being at *a*, and the ſloweſt at *g*; thus ſhowing that the velocity of a comet in its orbit continually and gradually decreaſes from the perihelion *a* to the aphelion *g*, and increaſes in the ſame proportion from the aphelion to the perihelion. The elliptical orbit is divided into twelve ſigns with their reſpective degrees, and in a ſimilar manner is the circle *n o p s t*, which repreſents a great circle in the heavens, and to which the motion of the comet is referred by the extremity of the wire W, moveable at S, and actuated by the ſtem of the comet, which ſlides againſt it, in and out alternately, in its progreſs in the orbit. During the comet's motion in its orbit from *f* to *g*, its apparent motion is only about five degrees in this circle, as pointed out by the end of the wire; but in the ſame time as the comet moves from *m* to *a*, or from *a* to *b*, it appears to deſcribe the large angular ſpace *t n*, or *n o* in the heavens, each of which arcs contains about 120°, or four ſigns; and if the eccentricity of the orbit were ſtill greater, the greater would be the difference between the two extreme velocities. The figures 1, 2, 3, 4, &c. to 12, repreſent a ſmall comparative circular orbit, for ſhewing the equable motion of a body, ſuppoſed to move concentrically round the ſun S, and to deſcribe equal arcs, as well as equal areas, 1 S 2, 2 S 3, &c. in equal times with thoſe of the comet *x* in its elliptic orbit before mentioned. Suppoſe now the bodies *x* and *o* to commence their motions at the ſame inſtant from the points *a* and 1, and to arrive at the ſame reſpective points again, after a revolution of each, at the ſame inſtant, it will be obſerved, during their progreſs, that the body *x* will be more forward than the body *o* in the firſt ſix ſigns from *a* to *g*, but more backward in the next ſigns from *g* to *a*, and the difference between the places of the two bodies, in any part of the ſmall or equable orbit, will be the *equation* of the centre in that particular part. At the points *a*, 1, and *g*, 7, the bodies are together, and conſequently the equation vaniſhes, and from thence begins to take an oppoſite character, changing from plus to minus, and *vice verſâ* at the reſpective points; alſo, the diſtance from the aphelion point, in the ſmall orbit, is called the *mean anomaly*, reckoned in ſigns and degrees; and the diſtance from *a*, in the large circle, reckoned in a ſimilar manner, is called the *true* or *equated anomaly*. Thus the reaſon appears evident, why, in aſtronomical calculations taken from the tables of Dr. Halley, or la Lande, the grand equation of a body moving in an elliptic orbit is *additive* in the firſt ſix ſigns, and *ſubtractive* in the ſecond ſix, with reſpect to the place aſcertained by an aſſumption of mean motion; and the ſame application of the grand equation, after ſome modification of its varying quantity, is uſed from the apogee to the perigee, and back again from the perigee to the apogee of the lunar orbit.

The mechaniſm, by means of which theſe motions are produced in the original cometarium, has been already explained above, from which that of Mr. Jones is very different, and is thus explained by him.

From the circumſtance of its being conſidered as impracticable to obtain an eaſy and uniformly ſteady motion of a comet, by Dr. Deſagulier's mechaniſm, Mr Jones has adopted the plan of uſing only one great wheel revolving on an arbor placed out of the centre, agreeably to the drawing exhibited in *fig.* 3. of *Plate* II. near the point H, and under the cock attached to the plane of the wheel, by three viſible ſcrews. The different parts and action of the mechaniſm are theſe; A B repreſents the inſide bottom of the box, ſeen in *fig.* 1. of the ſame plate; C D is an oblong piece of mahogany, fitted ſo as to ſlide eaſily but ſteadily in the grooves of two parallel ſide-pieces of the ſame wood, made faſt to the bottom, and denoted by the letters E and F; G is the large braſs wheel, about five inches diameter, which we have ſaid revolves on an eccentric arbor, near the point H; over this point is placed the cock, or bent arm, H I, with an oblong ſlit through it, to receive the ſliding piece *a*, which piece ſupports the low end of the ſtem that carries the comet X in *fig.* 1. K and L are two wheels pivoted above into a bridge P, ſhaped like a croſs, and have equal numbers of teeth, the latter of which wheels is actuated by the contrate wheel M, inſerted on the axis B, of the handle N; on the ſame arbor with K, and cloſe under the bridge P, is a ſmall wheel (ſeen in the figure) that impels the large wheel G, round its eccentric arbor; it will not perhaps appear evident to an ordinary mechanic, how the action of the ſmall and large eccentric wheel is rendered continual, and the pitching of the teeth made good all round the great wheel, notwithſtanding the conſtant variation of the diſtances from the eccentric point, which is the centre of its motion, and the ſucceſſive points of its circumference; to effect this apparently difficult purpoſe, conſiderable ingenuity was neceſſary; by examining the croſſes and rim of the large wheel, it will be ſeen, that the thickneſs of the croſſes, and of the teeth, is leſs than of the rim, ſo that the rim may be ſaid to have a circular edge-bar on its plane projecting upwards; this edge-bar is embraced by two rollers, the larger one moving round on the arbor of wheel K, above the ſmall wheel, and the ſmaller one carried by a cock O, faſt to the croſſed bridge P; ſo that, as the great wheel is urged round by the ſmall one, theſe two rollers give motion to the ſliding piece of wood C D, alternately in and out, and conſequently bring the teeth of the wheel borne by this ſliding piece, into a proper depth to act with its ſmall impelling wheel, in every part of the revolution of the former, which therefore acts as well, when the teeth are directed towards the centre of motion, as if the arbor had been in the centre of the wheel, and placed on a ſtationary bar. The wheel, however, has many more teeth coming ſucceſſively into action during one half of its revolution, round the eccentric point of its motion, than it has during the other; and on this circumſtance depends the variable velocity of the comet attached to its arm I, as it regards the ſaid centre of motion. We ſhall have occaſion to ſhew, in another place, that the equation, produced by this cauſe only, would be juſt one half of the proper equation of the centre, or very nearly ſo, provided the ſun were placed exactly over the centre of motion, or eccentric point of the wheel: it is alſo not difficult to ſhew, that if the wheel had no eccentric motion, but had the ſun placed at a ſimilar diſtance out of its centre of motion, one half of the due equation would alſo, in that caſe, be effected, ſuppoſing the circle of ſigns, pointed to by the wire, to be eccentric with regard to the wheel, and ſuppoſing the ſun to be in its centre; now, in the inſtrument before us, theſe two cauſes operate together to produce the total equation due to the orbit, where the eccentricity of the wheel is to its radius, and alſo the eccentricity of the ſun's poſition, at the oppoſite ſide of the wheel's centre, to the ſame, as the eccentricity of the comet is to the radius of its orbit. It muſt, however, be acknowledged, that the joint agency of the two ſaid cauſes of the equation, ſuppoſes the ſliding bar C D to be ſtationary, in which caſe the action of the wheels would ſoon be impeded; conſequently, that part of the equation which depends on the ſun's eccentric poſition, as it regards the wheel's arbor, is variable, and in ſome meaſure muſt derange the ſcale of equations, as it would have been, if the wheel's arbor had been ſtationary; the remedy for this ſmall deviation from perfect accuracy in the ſcale of equations thus produced by the joint agency of three cauſes, is beſt effected by making the ſtraight lines, that form the triangular areas, to correſpond, not to a geometrical meaſurement, but to the actual turns of the handle, one of which will correſpond to each triangular area, when the contrate wheel M, and alſo the ſmall wheel over K, have each one twelfth part of the number of teeth that the great wheel has, which wheel, in that caſe, may have any optional number that is diviſible by twelve. When the centre of the large wheel lies exactly in a line joining the centre of motion H, and the arbor of K, the ſliding board C D is the moſt puſhed out, and the comet is at the aphelion *g*, *fig.* 1. moving ſlowly; but when the centre of the wheel's motion lies between the central point of it and of wheel K, then the comet is at the perihelion *a*, moving quickly. The cock *y*, in *fig.* 1., holds the elliptic plate, with the triangular areas marked on it, and bearing on it the ſun, in ſuch a ſituation, that the groove round its edge, in which the ſtem of the comet moves, limits the diſtance at all times of this body, as it reſpects the ſun, which is done by making the ſliding piece in *fig* 3. move in or out in the ſlit of the arm I, already deſcribed. Thus the jerks of the old cometarium are avoided, and all its apparent properties are preſerved, except that a portion of the large graduated celeſtial circle is unavoidably concealed by the ſuperior elliptic plate of triangular areas.

COMETES, in *Botany*, (*κομητης*, *crinitus*, ſo called on account of the remarkably hiſpid involucres,) Linn. Mant. 39. Schreb. 211. Willd. 211. Lam. Ill. 203. Juſſ. 437. Claſs and order, *tetrandria monogynia*. Nat. Ord. *Tricoccæ.*

Gen. Ch. *Calyx common.* Involucre four-leaved, incloſing three ſeſſile flowers, oblong, equal, ciliate-hiſpid. *Calyx proper.* Perianth four-leaved; leaflets oblong, equal the length of the involucre. *Cor.* none. *Stam.* Filaments four, capillary, the length of the involucre; anthers roundiſh. *Piſt.* Germ ſuperior, roundiſh; ſtyle filiform; ſtigma trifid. *Peric.* Capſule tricoccous. *Seeds* ſolitary.

Eſſ. Ch. Involucre four-leaved, three-flowered. Calyx proper, four-leaved. Corolla none. Capſule tricoccous.

Sp. C. *alternifolia.* Linn. Syſt. Nat. Mart. Willd. Burm. Ind. 39. tab. 15. fig. 5. (Clinopodium parvum ſinicum; Pluk. Alm. 61. tab. 380. fig. 4.) *Root* annual. *Stem* a foot high, herbaceous. *Leaves* oppoſite, narrowing into a petiole, inverſely egg-ſhaped, acuminate, quite entire. *Peduncles* in pairs, terminal and axillary. A native of Surat.

COMETITES, in *Natural Hiſtory*, a name given by ſome writers to a kind of aſtroites, which has ſtars much larger than thoſe of the common kind, and therefore called *comets*.

COMEUS, in *Mythology*, a ſurname of Apollo, under which title he was worſhipped at Seleucia, whence his ſtatue was carried to Rome, and placed in the temple of Apollo Palatine.

COMFETS, Stony, in *Natural Hiſtory*, drop-ſtones or confetts. Theſe are ſtalactites, broken into ſhort pieces, ſomewhat reſembling comfets, and certain kinds of ſugar-plums, and which in Italy and other places are ſometimes put up in boxes and labelled, ſo as to deceive ſtrangers at firſt ſight, in ſuppoſing them to be real comfets.

COMFLOENTA, in *Ancient Geography*, a town of Spain, in the Tarragonenſian territory, placed by Ptolemy in the country of the Arevaci.

COMFORT, Point, in *Geography*, is the ſouth eaſternmoſt part of Elizabeth-city county, in Virginia, formed by James river, at its mouth in Cheſapeak bay; 19 miles W. by N. of Cape Henry.

COMFREY, or Comphry, in *Botany*. See Symphytum.

COMHOLA, in *Geography*, a river of Ireland, which runs into Bantry bay; 3 miles N. of Bantry.

COMI, in *Ancient Geography*, a people of Aſia, in Bactriana, ſaid by Ptolemy to have dwelled in the vicinity of the *Chomari*.

COMIDAVA, a town of Dacia, according to Ptolemy.

COMILLAH, in *Geography*, a town of Hindooſtan, in the province of Bengal; 160 miles E. N. E. of Calcutta, and 176 E. S. E. of Moorſhedabad. N. lat. 23° 25′. E. long. 91° 15′.

COMIN and Cominot, two ſmall iſlands in the Mediterranean, lying between Malta and Goſa or Gozo; the former ſuppoſed to be the Hepheſtia, or iſle of Vulcan of the ancients. They were formerly uninhabited; but by the care of Vingnacourt, a fort having been built upon each of them for their ſafety, they have been ſince partly inhabited, and that of Comin, which is about 4 or 5 miles in circuit, breeds a large quantity of cattle. See Malta.

COMINES, a town of Flanders, ſituated on the Lis, which divides it into two parts; formerly a conſiderable place, but reduced by war and various accidents; 25 miles S. of Bruges, and 7 N. of Lille.

COMINGE, in *Military Language*, a ſhell of uncommon magnitude, which takes its name from the perſon who invented it.

COMING-TO, in *Sea Language*, denotes the approach of a ſhip's head to the direction of the wind.

COMINIUM, in *Ancient Geography*, a town of Italy in Samnium, which did not ſubſiſt in the time of Pliny.

COMIOLA, in *Botany*, a name given by ſome of the old Roman authors, to the plant commonly called Luteola, or dyers' weed.

COMITATU *commiſſo*, in *Law*, a writ or commiſſion, by which a ſheriff is authoriſed to take upon him the charge of the county.

Comitatu *et caſtro commiſſo*, a writ by which the charge of a county, together with the keeping of a caſtle, is committed to the ſheriff.

COMITATUS, in *Law*, a county. Ingulphus tells us, that England was firſt divided into counties by king Alfred; and the counties into hundreds, and theſe again into tythings; and Forteſcue writes, that *regnum Angliæ per* comitatus, *ut regnum Franciæ per ballivatus, diſtinguitur*. Sometimes it is taken for a territory or juriſdiction of a particular place; as in Mat. Paris, anno 1234. See COUNTY.

COMITATUS *poſſe*. See POSSE.

COMITIA, an aſſembly of the Roman people, either in the Comitium, or Campus Martius, i. e. *Field of Mars;* meeting for the election of magiſtrates, or for conſulting on the important affairs of the republic.

The word comes from the verb *coeo*, or *comeo, to go together*.

There were certain days fixed for theſe aſſemblies, called *dies comitiales;* marked with a C in the calendar of Julius Cæſar. Comitial aſſemblies, held for the election of conſuls, were called *conſular comitia:* in like manner, the other comitia took names from the officer to be created; whether a tribune, a pontiff, ædile, or the like.

There were three kinds of theſe comitia, viz. *curiata*, *centuriata*, and *tributa;* ſo diſtinguiſhed from the manner wherein the people voted, and gave their ſuffrages, *viz.* by curiæ or pariſhes, tribes, or centuries.

The power of calling theſe aſſemblies pertained to moſt of the chief magiſtrates, and ſometimes to the ſovereign pontiff.

Authors make the difference between *comitia* and *concilia*, to conſiſt in this; that in the former the whole people were called together, in the latter only a part.

COMITIA *curiata*. Romulus inſtituted the *comitia curiata*, or the public aſſemblies of the people, called to vote in their ſeveral curiæ: and it is agreed by all that the matters ſubjected to their deciſion, were the choice of all the magiſtrates, and the right of making laws, war, and peace: an ample juriſdiction, comprehending the moſt important articles of government, yet not wholly abſolute, according to Dionyſius, unleſs the ſenate concurred with them. This method of tranſacting all the greater affairs by the people, aſſembled in their curiæ, after it had ſubſiſted through five ſucceſſive reigns, was found to be inconvenient.

Servius Tullius, the ſixth king of Rome, in order to correct the inconvenience of the *comitia curiata*, inſtituted a new diviſion of the people into ſix claſſes, according to a cenſus, or valuation of their eſtates; whence proceed the *comitia centuriata:* then he ſubdivided theſe claſſes into one hundred and ninety-three centuries, and contrived to throw a majority of theſe centuries, that is, ninety-eight of them, into the firſt claſs of the richeſt citizens. By which regulation, though every man voted now in his century, as before, in his curia; yet, as all matters were decided by a majority of the centuries, ſo the balance of power was wholly transferred into the hands of the rich; and the poorer ſort deprived of their former weight and influence in the affairs of ſtate: which wiſe inſtitution was ever after obſerved, through all ſucceeding ages, in the elections of the principal magiſtrates, and the determination of all the principal tranſactions of the republic.

COMITIAL *days*. Paulus Manutius is of opinion, that there were certain days on which the Roman ſenate might regularly be aſſembled; and others on which it could not: and that theſe laſt were called comitial days, and marked under that name in the calendars, as days wholly deſtined, and ſet apart by law, for the aſſemblies of the people. But Sigonius contends, that the ſenate might meet on any of thoſe days, unleſs when the people were actually aſſembled, and tranſacting buſineſs on them; and conſequently that the title of comitial denoted ſuch days only, on which the people might be legally aſſembled, not ſuch on which they were of courſe to be aſſembled. Middlet. of Rom. Senat. p. 138, ſeq.

The truth of the matter ſeems to be this, that though the days called comitial were regularly deſtined to the aſſemblies of the people, yet the ſenate alſo might not only be convened on the ſame, after the popular aſſemblies were diſſolved; but had the power likewiſe, whenever they found it expedient, to ſuperſede and poſtpone the aſſemblies of the people to another day; and, by a particular decree, to authoriſe their own meetings upon them, for the diſpatch of ſome important affair therein ſpecified.

COMITIALIS *morbus*, in *Medicine*, an ancient term for the *epilepſy*, or falling ſickneſs; ſo called, becauſe if any perſon was ſeized with it in the Roman comitia, the aſſembly was immediately diſſolved; this being eſteemed an unlucky omen; or, rather, becauſe thoſe liable to it were chiefly ſeized in the comitia, or great aſſemblies. See EPILEPSY.

COMITIUM, the place where the comitia were ordinarily held, which was a large hall in the Roman Forum: it was a long time open at top; on which account the aſſemblies were often interrupted by bad weather: it was firſt covered over in the time of the ſecond Punic war. See FORUM.

Roſinus obſerves, that the conſuls and tribunes were not created in the *comitium*, but in the Campus Martius.

It was in this place that the roſtra were placed. See COMITIA.

COMITLAN, in *Geography*, a town of North America, in Mexico, and province of Chiapa.

COMITOLO, PAUL, in *Biography*, one of the ableſt of the ſociety of Jeſuits, acquired great reputation by his inſtructions in morality and theology at the commencement of the ſeventeenth century. He died in 1626, at the age of eighty years. His publications are "Catena illuſtrium authorum in Librum Job," tranſlated from the Greek into the Latin language;— "Concilia ſeu reſponſa moralia:" "Doctrina de contractu univerſo." Nouv. Dict. Hiſt.

COMMA, in *Grammar*, a point, or character, formed thus [,]; ſerving to mark a ſhort ſtop, or pauſe; and to divide the members of a period.

The word is formed of κόπτω, *ſeco, I cut*.

It is very difficult to fix the preciſe uſe of the comma; different authors define and uſe it differently: the ordinary doctrine is, that the comma ſerves to diſtinguiſh nouns, verbs, adverbs, and the ſeveral parts of a period that are not neceſſarily joined together. But this conveys no clear, preciſe idea; for what is it to diſtinguiſh the parts of a period not neceſſarily joined together? F. Buffier has carried the doctrine of the comma farther: according to him, the comma ſerves to diſtinguiſh thoſe members of a period, in each whereof is a verb, and the nominative caſe of the verb. Thus, "That ſo many people are pleaſed with trifles is owing to a weakneſs of mind, which makes them love things eaſy to be comprehended."

Beſides this, the comma is uſed to diſtinguiſh, in the ſame member of a period, ſeveral nouns ſubſtantives, or nouns adjectives, or verbs, not united by a conjunction. Thus, "Virtue, wit, knowledge, are the chief advantages of a man:" or, "A man never becomes learned without ſtudying conſtantly, methodically, with a juſt application, &c."

If thoſe words be united in the ſame phraſe by a conjunction, the comma is omitted: thus, "The imagination and the judgment do not always agree." The comma may alſo be omitted between the phraſes that are very ſhort, eſpecially if they depend upon the ſame regimen, and are united by a conjunction: thus, "Alexander conquered Aſia and eſtabliſhed the monarchy of the Greeks."

The ingenious author of the tract "De Ratione Interpungendi," printed with Voſſius's Element. Rhetor. Lond. 1724. lays down the uſe of a comma to be, to diſtinguiſh the ſimple members of a period, or ſentence; i. e. ſuch as only conſiſt of one ſubject, and one definite verb. Thus Cicero, "Venio nunc ad voluptates agricolarum, quibus ego incredibiliter delector, quæ nec ulla impediuntur ſenectute, & mihi ad ſapientis vitam proxime accedere videntur." See SENTENCE.

But this rule does not go throughout; the ſame author inſtancing many particular caſes, not included herein, where yet the comma is adviſable.

Sometimes, *e. gr.* a propoſition includes another, which may be called *partitive*, as being only a part of the entire phraſe; in which caſe, the two are to be divided from each other by commas. Thus, "He always ſays, as he tells us, the fineſt things in the world."

The points, or pauſes in diſcourſe, it is obſerved, are in a kind of muſical proportion: the comma ſtops the reader's voice while he may privately tell one; the ſemicolon, two; the colon, three; and the period, or full-ſtop, four. Others make the ſtop at the colon four: and the period ſix. Profeſſor Ward obſerves, that the ſuſpenſion of the voice ſhould be twice as long for a comma, as between words ſeparated by no mark of diſtinction; thrice for the ſemicolon; and ſo in the ſame proportion. Biſhop Lowth aſſigns to the period a pauſe in duration double to the colon: to the colon, double of the ſemi-colon; and to the ſemicolon, double of the comma: ſo that they are in the ſame proportion to one another as the ſemibreve, the minim, the crotchet, and the quaver in muſic. But whatever be the duration of the ſeveral pauſes, the proportion between them would be ever invariable, if the doctrine of punctuation were exact. Introd. to Engliſh Grammar, ed. 1772. p. 197.

The ancients only made uſe of two kinds of points, or pauſes, in a period; the larger they call *members*, the Greeks *cola*, marked thus [:]; the ſmaller *inciſa*, the Greeks *commata*, thus [,].

The moderns, refining on their predeceſſors, have ſubdivided the firſt into a colon, and ſemi-colon; ſome ſay, without any good foundation in nature; though others maintain the uſefulneſs of the diviſion.

As the member, or colon, divides the period into two parts, each containing a ſenſe, though that imperfect: thus, "Antequam de republica, patres conſcripti, dicam ea quæ dicenda hoc tempore arbitror;" where the ſenſe does not reſt, nor is the period or ſentence perfect, without the addition of "exponam vobis breviter & profectionis & reverſionis meæ:" the comma ſubdivides each member into intermediate diviſions, which, of themſelves, have no preciſe meaning at all: *v. gr.* "Nihil eſt, mihi crede, virtute formoſius, nihil pulchrius, nihil amabilius."

Frequent commas, as on other occaſions they promote perſpicuity and diſtinctneſs, and eaſe the reader, both in the rehearſal and comprehenſion of his author; ſo, in oratory, are of eſpecial uſe and effect; particularly where an adverſary is to be cloſely and pointedly attacked, upbraided, reprehended, wounded, &c. Witneſs that of Cicero againſt Verres: "Non enim nos color iſte ſervilis, non piloſæ genæ, non dentes putridi deceperunt: oculi, ſupercilia, frons, vultus denique totus, qui ſermo quidam tacitus mentis eſt, hic in fraudem, homines impulit: hic, eos, quibus erat ignotus, decepit, fefellit, in fraudem induxit: pauci tua iſta lutulenta vitia novimus; pauci tarditatem ingenii, ſtuporem, debilitatemque linguæ," &c. On the uſe of commas, ſee Murray's Engliſh Grammar, ed. 8. p. 224, &c.

COMMA, in *Muſic*. By this term, theoretic writers on muſic have denominated ſeveral different ſmall intervals in the muſical ſcale, which makes it neceſſary that we ſhould here enter rather minutely into the ſubject. We ſhall begin with that very eſſential interval in almoſt all muſical calculations which is for the moſt part implied by the word comma without further addition, otherwiſe the

COMMA *Major*, *Greater Syntonic* or *Elementary* of various writers, being alſo the *ſchiſm* or *ſchiſma* of Des Cartes, Holder, and others. This interval ſeems firſt to have been noticed by the Greek writers, as the quantity by which the major tone T ($\frac{8}{9}$) exceeds the minor tone *t* ($\frac{9}{10}$); its ratio is $\frac{80}{81}$ and its value in the common or Briggs's logarithms is .9946049,6811, or when reckoned downwards .0053950,3189; and in the logarithms of Euler .017920: this laſt being, in fact, its decimal value, compared with the octave = 1. This comma is uſually marked C, and is equal to 11.0078631 times the *ſchiſma* (Σ) = to 73.55198 times the leſſer fraction *(f)* = to 1400.0913 times the minute (m), and = to $\frac{1}{55.8}$ of the octave nearly.

It is equal to the ſum of 11 ſchiſmas and a minute, ($11\,\Sigma + m$), or of a minor comma and a ſchiſma: it alſo reſults as the difference or remainder, after ſubtracting the following intervals from each other, *viz.* a ſchiſma from a diaſchiſma, a minor comma from an enharmonic dieſis, a ſemitone minor from a ſemitone medius, a ſemitone medius from an apotome, (here obſerving that $\frac{2187}{2048}$ is the apotome and not $\frac{2127}{2048}$, erroneouſly printed in our article), an enharmonic dieſis from a ſemitone minimum, a limma from a ſemitone major, a ſemitone major from a ſemitone maximum, a ſemitone ſubminimum from a ſemitone minor, &c. The comma major is equal to the following additions of intervals, in triples, *viz.* two ſchiſmas, a medius reſidual and a major reſidual; three ſchiſmas, a minor reſidual and a major reſidual; five ſchiſmas, a leſſer fraction and a major reſidual; ten ſchiſmas, a leſſer fraction and a greater fraction; ten ſchiſmas, three leſſer fractions and a medius fraction, &c. See theſe ſeveral articles.

The curious, and thoſe concerned in theſe kinds of calculations, will find a great variety of other relations, in which the comma major ſtands, to the muſical intervals, both great and ſmall, in the elaborate manuſcript treatiſes on muſic by the late Marmaduke Overend, organiſt of Iſleworth, and by the late Dr. Boyce, which Dr. Callcott lately preſented to the library of the Royal Inſtitution in Albemarle-ſtreet, after kindly permitting the writer of this article to peruſe and extract from them for the uſe of this work. The ratio of the major comma may be reſolved into the component primes $\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{5}$, and then, according to the method of Mr. Farey in the Philoſophical Magazine, vol. xxvii. p. 193, (ſee our articles *Muſical* PRIMES, and *Tuneable* INTERVALS) can be reſolved into factors $\frac{3}{2}$, $\frac{3}{2}$, $\frac{3}{4}$, $\frac{3}{5}$ or two fifths (V) reverſed, a fourth (IV) and a major ſixth (VI); whence it appears, that the interval of a major comma can be tuned on an inſtrument, having a ſufficient number of ſtrings or pipes, by tuning two fifths downwards in ſucceſſion, and thence upwards a major ſixth, and a minor fourth in ſucceſſion, or VI + 4 − 2 V; where it is obſervable, that two Vths might have been tuned upwards, and a V and 4th downwards, which would alſo produce the interval of a major comma, but *above* the firſt or key note, inſtead of *below* it, as in the firſt caſe, where VI + 4 − 2 V is a negative quantity, as well as all the following. The fraction $\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{2}\cdot\frac{3}{5}$, does not at firſt appear capable of diviſion into any other tuneable ratios, than the above: but, if we multiply the ſame by $\frac{5}{5}$, it will then be reſolvable into the factors $\frac{3}{5}$, $\frac{3}{5}$, $\frac{5}{4}$, $\frac{3}{2}$, $\frac{3}{2}$, and may be tuned thus, 2 VI — III — 2 V; or multiplying by $\frac{2}{2}$, we can obtain 2 fourths — V — 3; or if by $\frac{4}{4}$, we can get 2 fourths + III — 2 V; if by $\frac{2}{2} \times \frac{2}{2} \times \frac{2}{2}$, we may get 3 fourths — 6 — V; and if by $\frac{2}{2} \times \frac{2}{2} \times \frac{5}{5}$ we ſhall have 2 fourths — III — 2 thirds: and thus, we have ſix methods of exactly tuning a major comma, either above or below any given note, by help of perfect intervals only.

The method above explained, of analyſing muſical ratios or intervals, and expreſſing them in different ways, by the uſe of tuneable intervals only, is calculated to inſtruct the muſical ſtudent, in the curious and important relations which the ſeveral concordant intervals bear to each other: hence we ſee, for inſtance, that if in any chant, or paſſage in a melody, to be performed by voices, by violins, or other perfect inſtruments, any one of the above ſix ſucceſſions of notes were to occur, and the intervals were all to be performed perfect, or without temperament in the melody, the concluſion would not be in the key-note, or that ſet out from, but a comma different in pitch, which property of the muſical ſcale is called *divergency of tune;* ſee that article.

It is obſervable, that all of the above ſix expreſſions or paſſages in melody, which diverge a comma, contain two *fifths* or two *fourths*, each moving the ſame way, and to which the divergency ſeems attributable, when the ſame is not counteracted by a proper ſucceſſion of other intervals. Mr. Maxwell in his "Reformed or Complete Diatonic Scales for the Organ and Violin," &c. in his "Eſſay on Tune," (and ſo does Overend in his manuſcripts) propoſes to mark the riſe of a comma by the acute accent (ʹ), and the fall of the ſame by the grave accent (ˋ), and that when either of theſe are required to be taken off, this mark (°) is to be uſed, in the writing of muſic, in the ſame way as the muſical mark ♮ is uſed, to take off or deſtroy the effect of a ♯ or ♭, which has gone before, either accidentally, or in the ſignature of the ſtaff. Mr. Maxwell ſhews, how a violin performer may practically tune a *comma* upon his inſtrument, in a variety of ways.

Modern writers on the temperament of the muſical ſcale, uſually refer their temperaments, or ſmall corrections, to be applied to the concords, to this major *comma* as a unit or ſtandard, on which account we ſhall preſent our readers with ſome further particulars relating to this ſmall interval of the ſcale. Dr. Robert Smith, in his "Harmonics," Lemma to the 9th propoſition, cor. 4, has demonſtrated, that if any part or parts of a comma *c*, denoted by $\frac{q}{p}c$, be the interval of imperfect uniſons (or temperament), the ratios of the times of their ſingle vibrations will be $161\,\underline{p} - \underline{q}$ to $161\,\underline{p} + \underline{q}$, extremely near: for example, if we want a finite or approximate ratio for a $\frac{1}{4}$ of a comma, we have $q = 1$, $p = 4$, and $\frac{161 \times 4 - 1}{161 \times 4 + 1} = \frac{643}{645}$ is the ratio, the complement arithmetical of its logarithm being 13487, which is true to the laſt of 7 places of figures: in like manner, $\frac{161 \times 3 - 1}{161 \times 3 + 1} = \frac{482}{484}$ or $\frac{241}{242}$ is the ratio anſwering to $\frac{1}{3}c$, or $\sqrt[3]{\frac{80}{81}}$, which is alſo true to the laſt of 7 places in the logarithm, and is ſufficiently accurate for all purpoſes: but it muſt be noticed that theſe are not compoſed of muſical primes.

It may be of uſe here to enquire, what proportion the major *comma*, or ratio of $\frac{80}{81}$, bears, to the hemitone or ratio of $\frac{15}{16}$; for which purpoſe we have the logarithm of the latter divided by the logarithm of the former, or $\frac{280287}{539501} = 5.195282$, the number of major commas in one hemitone (or H) very nearly: and as it may be uſeful on many occaſions for the ſtudent to know, how many major commas make up any interval, we have ſubjoined a ſhort table, ſhewing very exactly how many major commas make up the different concords within the octave, and alſo ſome of the ſmaller diſcords.

Intervals.	Ratios.	N°. of Commas.
VIII	$\frac{1}{2}$	55.797636
VI	$\frac{3}{5}$	41.120938
6th.	$\frac{5}{8}$	37.834808
V	$\frac{2}{3}$	32.639526
4th.	$\frac{3}{4}$	23.158110
III	$\frac{4}{5}$	17.962828
3rd.	$\frac{5}{6}$	14.676696
II	$\frac{8}{9}$	9.481414
IIʹ	$\frac{9}{10}$	8.481414
2nd.	$\frac{15}{16}$	5.195282
comma	$\frac{80}{81}$	1.000000
Key.	$\frac{1}{1}$	0.000000

From the above table it appears, that the octave, whoſe ratio is $\frac{1}{2}$, contains ſomething more than $55\frac{3}{4}$ major commas, the VI. a little more than 41 commas, &c. We ſhall next conſider the

Comma *Minor*, or *Leſſer*, of Rameau, Overend, &c., being alſo the *apotome* minor of Salomon de Caus, Boetius, &c. the *diaſchiſma* of Euler, and the major *dieſis* of Maxwell. This interval ſeems firſt to have been noticed by the Greek writers, as the quantity by which two *ſemitones* major 2 S $\left(\frac{15}{16} \times \frac{15}{16}\right)$ exceeded the *tone* major T $\left(\frac{8}{9}\right)$. Its ratio is $\frac{2025}{2048}$, and its value in Briggs's logarithms .9950950,7525, which reckoned downwards, by its arithmetical complement, is .0049049,2475; and its value in Euler's logarithms is .016295, being that decimal part of an octave. The minor comma is marked by Overend, Dr. Boyce, Dr. Callcott, and others, with a daſhed *c*, (ɛ), ſimilar to the mark for ſcruple in apothecaries weight, but reverſed. (See Philoſophical Magazine, vol. xxviii.) It is equal to 10.007863 times the ſchiſma (Σ) = to .909170 times, or nearly $\frac{10}{11}$ths of the major comma. It is equal to the ſum of ten ſchiſmas and one minute (10 Σ + *m*). And it reſults as the difference when a ſchiſma is taken from a major comma, a diaſchiſma from two major commas, two major commas from a ſemitone minimum, a major comma from an enharmonic dieſis, a ſemitone minor from a limma, an apotome from a ſemitone maximum, a ſemitone minimum from two enharmonic dieſes, a ſemitone medius from a ſemitone major, a leſſer fraction from a priſma, two ſchiſmas from a diaſchiſma, a hyperoche from a ſemitone ſubminimus, two ſemitones medii from a tone major, &c. The comma minor is equal to the following additions of intervals in triples, viz. a ſchiſma, a major reſidual and a medius reſidual; two ſchiſmas, a major reſidual and a minor reſidual; four ſchiſmas, a major reſidual and a leſſer fraction; ſix ſchiſmas, a greater fraction and a medius reſidual; nine ſchiſmas, a greater fraction and a leſſer fraction; nine ſchiſmas, a medius fraction and two leſſer fractions, &c. (See Overend's MS. before quoted.)

The ratio of this interval is compoſed of theſe primes, $\frac{3^4 5^2}{2^{11}}$, which reſolved as ſhewn above, give ^{3}4ths — V — ^{2}III, and ^{3}4ths — ^{2}III — 3, as different methods of practically tuning the minor comma upon an organ, piano-forte, &c.

Comma *Maximum*, of Pythagoras, Boetius, &c. or ancient comma; this interval, whoſe ratio is $\frac{524,288}{531,441} = 12\ \Sigma + m$, is now called the Diaschisma; ſee that article.

Comma, *Greater*, has erroneouſly been applied by ſome to the ratio $\frac{125}{138} = 21\ \Sigma + 2\ m$, which is the *Enharmonic* Diesis; ſee that article.

Comma *Minimum*, according to ſome former writers, expreſſes the ratio $\frac{32768}{32805} = \Sigma$, which is now called the Schisma; ſee that article.

Comma, *Ancient*, according to Galileo, had a ratio of $\frac{625}{648} = 32\ \Sigma + 3\ m$, which is now called the Semitone *Minimus*, which ſee.

Comma *of Philolaus*, is the ratio of $\frac{229}{230}$, intended as an approximation for $\frac{1}{27}$th part of a tone major, but which it exceeds conſiderably; beſides, the fraction $\frac{229}{230}$ is not compoſed of the ſmall or muſical primes 2, 3, and 5, and cannot therefore be admitted into muſical computations.

Comma *of Boetius*, according to Glareanus, alſo of D. Nicola was $\frac{1}{9}$th part of the tone major, or $11\frac{5}{9}\ \Sigma + \frac{2}{9} f + m$, whereof 5 made their ſemitone majus or apotome, and 4 made their ſemitone minus or limma: this interval was anciently ſuppoſed by ſome to be the ſame with the modern diaſchiſma ($12\ \Sigma + m$), but from which it differs, $\frac{4}{9}\ \Sigma - \frac{2}{9} f = .477702 \times \Sigma$, or nearly half a ſchiſma.

The ancients mention another comma, $\frac{1}{8}$ of the tone minor, or $11\frac{5}{8}\ \Sigma + \frac{1}{4} f + m$. (See Dr. Callcott's "Muſical Grammar," pages 119 and 49.

Comma, *Artificial*, of Nicholas Mercator, is the $\frac{1}{53}$ part of the octave, or $11\frac{29}{53}\ \Sigma + \frac{12}{53} f + m$. (See Mercator's "Temperament of the Muſical Scale").

Comma of *Merſennus*. According to Holder's "Treatiſe on Harmony," page 104, Merſennus divided the octave into about 58½ parts, and called one of theſe a comma.

Comma of *Galileo*. The interval $\frac{521441}{524288}$, called a comma in the writings of this author, was intended to have been the diaſchiſma or $\frac{524288}{531441}$, as Mr. Overend has ſhewn, vol. i. p. 140, of his MS. before referred to; the error originated in an erroneous multiplication, in the ſecond figure of Galileo's numerator, by which it was rendered unfit for the muſical ſcale. (See ſir John Hawkins Hiſt. Muſ. vol. i. p. 321.)

Comma *and half* of *Galileo*, has a ratio of $\frac{625}{648} = 32\ \Sigma + 3\ m$, which is the Semitone *minimum*; ſee that article.

Comma *and half* of *Rameau*. This interval reſults from the addition of a major comma and a major reſidual, and is alſo the difference between a ſemitone ſubminimus and a hyperoche; its ratio is $\frac{1953125}{1990625}$, its common logarithm is .9917338,2179 and Euler's log. $0.027456 = 17\ \Sigma - f + 2\ m$. The component primes of this ratio are $\frac{5^9}{2^{13}3^5}$, whence it appears, from the proceſs before explained, that ^{5}3 — ^{4}III, or five minor thirds upwards, and four major thirds downwards, furniſh a practical method of tuning this interval above any note, and the reverſe of this proceſs or ^{4}III — ^{5}3 would tune the ſame below any given note.

Comma, *Semi*. See-Semi-Comma.

Comma *Redundant*, or *ſuperfluous*, or *deficient*, or *diminiſhed;* theſe terms are applied to ſuch intervals, whether concords or diſcords, as exceed or fall ſhort of the true ratio of that interval by a major comma, as a comma redundant fifth, a comma deficient third, &c. Sometimes the term comma is omitted in naming theſe intervals, as a redundant fifth, a deficient third, &c. See Fifth, Third, &c.

COMMAGENE, or Comagene, *Kamaſh*, in *Ancient Geography*, a country of Syria, bounded on the weſt by mount Amanus, on the north by part of mount Taurus, on the eaſt waſhed by the Euphrates; and with regard to its ſouthern boundaries, it is uncertain whether it is contiguous to Seleucia, Cyrrheſtica, or both. It is near the north corner of Syria. This country is mentioned by Strabo, Ptolemy, Pliny, and Ammianus Marcellinus, but they aſſign to it different extents. Its chief cities were Samoſata upon the Euphrates, its capital, Antiochia ad Taurum, Germanicia, Singa, Chaonia, and ſeveral other cities, once of great note, but long ſince utterly deſtroyed. In the time of Antiochus the Great, Commagene was ſubject to the Syrians, and left to him by the treaty of peace which he concluded with Rome, after the famous battle of Magneſia; and hence it is probable, that it was ſeized by ſome of the princes of the Seleucian family, during their inteſtine wars, as no mention of the kings of Commagene occurs till the time of Pompey, and the names of thoſe, who afterwards reigned there, are altogether Syrian. The firſt that is mentioned is Antiochus, who joined with Darius king of Media, in oppoſing the entrance of Pompey into Syria, after the defeat of Tigranes; but, being overcome in battle, he ſubmitted to the conqueror, and was not only confirmed in his kingdom, but rewarded with part of Meſopotamia. In the civil war between Cæſar and Pompey, he ſent large ſupplies to the latter. Antiochus having been put to death by order of Auguſtus, for the aſſaſſination of the Roman ambaſſador, was ſucceeded by Mithridates, on whom Auguſtus beſtowed the kingdom of Commagene, in recompence of his ſervices during the war with Antony and Cleopatra. Upon the death of Mithridates, Antiochus II., the ſon of Antiochus I., was permitted by Auguſtus to take poſſeſſion of the kingdom. This prince died in the reign of Tiberius; and Commagene became a Roman province, and at the requeſt of the nobles, it was governed by a prætor. But Caligula reſtored the kingdom to Antiochus III., the ſon of Antiochus II., adding to it the maritime parts of Cilicia. He was ſucceeded by his ſon Antiochus IV., ſurnamed Epiphanes, who diſtinguiſhed himſelf under Veſpaſian in his war with the Jews, and particularly at the ſiege of Jeruſalem. Veſpaſian, however, having reduced Commagene to the form of a Roman province, would not allow any of the ſons of Antiochus to ſucceed him. This country was afterwards made part of the province called Auguſtophratenſis, or as Ammianus has it, Euphratenſis, and was commonly known by the name of Euphratenſia.

COMMAND, in French *Commandement*, in *Military Language*; the act or action of him who commands; a thing commanded; the right of commanding and making one's ſelf obeyed. The movements of a battalion at exerciſe, are performed by the words which the major or commanding officer pronounces. Hence, *the word of command* is a phraſe in common uſe among military people.

COMMAND denotes alſo authority. Every command falls to the eldeſt officer in the ſame circumſtances, whether he belong to the horſe dragoons, artillery, engineers, foot, or marines. In our ſervice when the commiſſions of two officers are of the ſame date, a retroſpection of former commiſſions takes place, or length of ſervice is examined into, and the diſpute, if any ariſes, is determined according to precedents, and the rules of war.

COMMAND, in the *Royal Navy*, implies the rank or power of an officer, who has the management of a ſhip of war of any kind under twenty guns. He ranks with a major in the army.

COMMANDANT, or COMMANDER, the perſon who commands an army, a brigade, a garriſon, a fort, caſtle, regiment, company, &c.

COMMANDE, a rope made uſe of for boats and pontoons.

COMMANDER, is a name given to a large wooden mallet uſed in a ſhip.

COMMANDERY. See COMMANDRY.

COMMAND *in front*, in *Fortification*, a height, or an eminence, which is directly oppoſite to, or faces the work, that it commands.

COMMAND *in rear*, an eminence or a height, which is directly behind the work that it commands.

COMMAND *in flank*, or *by enfilade*, a height or an eminence on the flank, or prolongation of any part of a work, which it ſees and looks along.

COMMANDEMENT, *Fr.* A commanding ground, an eminence or elevation, which overlooks a poſt or ſtrong place. There are three ſorts of *commandemens;* namely the *commandement in front*, which faces a work, and batters or fires on it in front; the *commandement en revers*, or *in reverſe*, which is behind a work or place, and fires on its rear either directly or obliquely; and the *commandement de courtine or in enfilade*, which is on the flank of a work, and fires along the whole extent of a rectilinear part of it. Nine feet in perpendicular height, conſtitute a ſimple command or *commandement;* 18 feet a double one; 27 feet a triple one; and ſo on.

COMMANDEMENT, *Order of, among the officers of infantry and cavalry.* In France it was cuſtomary in a place of war, and every incloſed city, for the officers of infantry to have the command over thoſe of the cavalry, and on the other hand to be commanded by them in the open field.

COMMANDEUR, Fr. The commander of an order of knights. In ſome orders of chivalry it is the title, which a profeſſed knight takes the moment he pronounces the vows, that ſubjected him to celibacy without his ceaſing on that account to be military. There are, however, in Spain orders of chivalry, that do not require celibacy on the part of the commanders.

COMMANDEUR, in *Ornithology*, the French name of *Oriolus Phoenicæus*, which ſee.

COMMANDINUS, FREDERICK, in *Biography*, was born at Urbino, in Italy, 1509. He was deſcended from a noble family, and celebrated for his great claſſical learning, and for his extenſive acquaintance with the mathematical ſciences. He was patronized by Francis Moria, duke of Urbino, and by his liberality enabled to publiſh tranſlations of various parts of the works of Archimedes: the Conics of Apollonius; the Elements of Euclid, and many other works of high reputation. He was alſo author of a book entitled, "De Centro Gravitatis Solidorum." Bologn. 1565; and of another entitled, "Horologiorum Deſcriptio" Romæ, 1562. He died in 1575; a funeral oration was delivered in his praiſe, by Antonio Toroneo. Gen. Biog.

COMMANDMENT, in a *Legal Senſe*, has various uſes: as, *Commandment of the king*, when on his own mere motion, and from his own mouth, he caſts a man into priſon.

Commandment of the juſtices, is either *abſolute* or *ordinary; abſolute*, as when, on their own authority, and their own diſcretion, they commit a man for contempt, &c. to priſon, as a puniſhment. *Ordinary*, as when they commit him rather for ſafe cuſtody, than puniſhment.—A man committed by an ordinary commandment is repleviable. Perſons committed to priſon by the ſpecial command of the king were not formerly bailable by the court of king's bench; but at this day, the law is otherwiſe. 2. Hawk. P. C. c. 15. § 36.

COMMANDMENT, is alſo uſed for the offence of him who directs or wills another to tranſgreſs the law; as by murder, theft, and the like. See ACCESSORY.

He that commandeth any one to do an unlawful act, is acceſſory to it and all the conſequences, if it be executed in the ſame manner as commanded: but if the commander revoke the command; or if the execution varies from it, or in the nature of the offence; in ſuch caſe he will not be acceſſory. 3 Inſt. 51, 57. 2 Inſt. 182.

In another ſenſe of this word, magiſtrates may command others to aſſiſt them in the execution of their offices, for the doing of juſtice; and ſo may a juſtice of peace, to ſuppreſs riots, apprehend felons; or any officer to keep the king's peace, &c. Bro. 3.

A maſter may command his ſervant to drive another man's cattle out of his ground, to enter into lands, to ſeize goods, to diſtrain for rent, or to do other things; if the thing be not a treſpaſs to others. The commandment of a thing is good; where he that commands hath power to do it; and a verbal command is in moſt caſes ſufficient; unleſs it be, where it is given by a corporation, or when a ſheriff's warrant is to a bailiff to arreſt, &c. Bro. 288. Dyer, 202.

In treſpaſs, &c. the maſter ſhall be accountable for the act of the ſervant done by his command; but ſervants ſhall not be excuſed for committing any crime, when they act by command of their maſter, who have no authority to give ſuch commands. The commands of infants and feme coverts are void; but in forcible entries, &c. an infant or feme covert may be guilty in reſpect of actual violence done by them in perſon.

COMMANDMENTS, *Ten*. See DECALOGUE.

COMMANDRY, or COMMANDERY, a kind of benefice, or fixed revenue belonging to a military order, and conferred on ancient knights, who had done conſiderable ſervice to the order.

There are *ſtrict*, or *regular* commandries, obtained in order, and by merit: there are others of *grace* or *favour*, conferred at the pleaſure of the grand maſter.

There are alſo commandries for the religious in the orders of St. Bernard and St. Antony.—The kings of France have converted ſeveral of the hoſpitals for lepers into commandries of the order of St. Lazarus.

The commandries of Malta are of different kinds; for as the order conſiſts of knights, chaplains, and brother ſervitors, there are peculiar commandries, or revenues, attached to each.

The knight to whom one of theſe benefices or commandries is given, is called commander: which agrees pretty nearly with the *præpoſitus* ſet over the monks in places at a diſtance from the monaſtery, whoſe adminiſtration was called *obedientia*: becauſe depending entirely on the abbot who gave him his commiſſion. Thus it is with the ſimple commanders of Malta, who are rather farmers of the order than beneficiaries; paying a certain tribute, or rent, called *reſponſio*, to the common treaſure of the order.

The commandries belonging to the priory of St. John of Jeruſalem in England, conſiſting of manors, lands, &c. ſuch was that of New Eagle in Lincolnſhire, Selbach in Pembrokeſhire, and Shengay in Cambridgeſhire, were given to Henry VIII. by ſtatute 32 Hen. VIII. c. 20.; ſo that the name of commandries only remains, the power being long ſince extinct.

COMMANI, in *Geography*. See COMMENDO.

COMMANIPULARIS, in *Ancient Military Language*, a Roman ſoldier, who could not ſleep but with his own century, nor fight but under its ſtandard.

COMMANOES, in *Geography*, one of the ſmall Virgin iſles in the Weſt Indies, ſituated to the N.N.E. of Tortola. N. lat. 18° 25′. W. long. 63°.

COMMANTAWANA, a bay on the north coaſt of the iſland of St. Vincent, about one mile eaſt of Tarraty point.

COMMARCHIO, in *Antiquity*, the confines of the land; whence probably is derived the word *marches*. "Imprimis de noſtris landimeris, *commarchionibus*." Du-Cange.

COMMARODES, in *Ancient Geography*, a place of Thrace, in the vicinity of Conſtantinople.

COMMEATUS, in *Military Language*, a paſsport or permiſſion granted to a Roman ſoldier to abſent himſelf from the army for a fixed or limited time. The ſame name was alſo given to ſoldiers' proviſions and their eſcorts.

COMMELIN, JOHN, a diſtinguiſhed botaniſt, was born at Amſterdam, July 23, 1629. He ſucceeded his father as one of the magiſtrates of the city, and while holding this office, was very active in forming a new botanical garden; the ground occupied by the old gardenhaving been taken into the city. The ſecond and third volumes of the "Hortus Indicus Malabaricus," owe much of their value to his judicious notes and obſervations. He publiſhed "Catalogus Plantarum indigenarum Hollandiæ," 1683, 12mo. It contains a liſt of 776 plants; and, in 1789, "Catalogus Plantarum Horti Medici Amſtelodami, pars prior." Theſe have been frequently reprinted. While preparing to complete this work, he died at Amſterdam in 1692.

COMMELIN, GASPAR, nephew to John Commelin. After taking his degree of doctor in medicine, he was appointed profeſſor in botany, and director of the garden at Amſterdam, offices which he filled with diſtinguiſhed ability and attention. He completed the work begun by his uncle, which he publiſhed in 1701. His next production was "Flora Malabarica, ſeu Horti Malabarici Catalogus," ſerving as an index to the Hortus Malabaricus. This was followed by "Præludia Anatomica," 4to. 1703; and the ſame year, "Præludia Botanica," with figures for the benefit of ſtudents in thoſe arts. In 1715, he publiſhed, "Icones Plantarum, preſertim ex Indiis Collectarum," 4to.; and, in 1718, "Botanographia Malabarica, a Nominum Barbariſmis reſtituta," Lugduni Bat. folio. All uſeful to ſtudents in botany, but ſerving rather to ſhew the great induſtry, than the genius of the writer. Haller. Bib. Botan. Eloy. Dict. Hiſt.

COMMELINA, in *Botany*, (ſo named by Plumier from the two brothers, John and Gaſpar Commelin, celebrated Dutch botaniſts.) Plum. 38. Linn. Gen. 62. Schreb. 86. Willd. . 104. Lam. Ill. 83. Gært. 56. Juſſ. 15. Vent. 2. 152. Claſs and order, *triandria monogynia*. Nat. Ord. *Enſatæ*. Linn. *Junci*, Juſſ. *Joncaceæ*, Vent.

Gen. Ch. *Cal. common*. Spathe heart-ſhaped, converging, compreſſed, very large, permanent. *Cal. proper*. Perianth, three leaved; leaves egg-ſhaped, concave. *Cor*. Petals three, unguiculated, larger than the calyx, alternating with its leaves; one ſometimes ſmaller. *Stam*. Filaments two, three, or ſix, awl-ſhaped, reclined; anthers oblong, verſatile. *Nect*. three, often cruciform, fixed to the top of their proper filaments, riſing above the ſtamens. *Piſt*. Germ ſuperior, roundiſh; ſtyle awl-ſhaped, revolute, ſtigma ſimple. *Peric*. Capſule, ſomewhat globular, two or three-celled; two or three-valved. *Seeds* few.

Eſſ. Ch. Calyx proper, three-leaved. Petals three, unguiculated. Nectaries three, on their proper filaments.

Obſerv. Linnæus conſiders the ſpathe as the only calyx, and attributes ſix petals to the flower; three exterior, ſmall, reſembling a perianth, and three interior, very large, coloured.

** Two petals larger; one ſmall.*

Sp. 1. C. *communis*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Encyc. 598. Ill. Willd. 1. Dill. Elth. tab. 78. fig. 89. Gært. tab. 15. fig. 1. Lam. Ill. tab. 35. fig. 1. Kooſcki. Kempf. Jap. 888. tab. 889. β. C. *polygama*; Roth. Catalect. Bot. 1. p. 1. "Leaves ovate-lanceolate, acute, ſtem creeping, ſmooth." *Root* annual. *Stems* ſeveral, two feet long, jointed, branched, leafy. *Leaves* alternate, nerved, ſupported by a membranous ſheath with ſhort hairs at its edge. *Flowers* axillary, two or three together, on ſhort peduncles; two of the petals blue, the third whitiſh green. *Capſule* egg-ſhaped, ſlightly compreſſed on each ſide, ſomewhat two-edged, two-celled, two-valved; valves thin, membranous, with the longitudinal partition on their inner ſide. *Seeds* two in each cell, affixed to the valves near the inſertion of the partition, two adhering to each valve, gibbous and pitted on one ſide, flat and furrowed, with a longitudinal line on the other, truncate at the end where they are oppoſite to each other, umbilicated. A native of North America, Africa, and Japan. β. differs only in having polygamous diandrous flowers. In all other reſpects it exactly correſponds with C. communis, of which it appears to be only a variety. Willd, 2. C. *africana*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. 599. Willd. 2. Gært. tab. 15. fig. 3. Lam. Ill. tab. 35. fig. 3. "Leaves lanceolate, ſmooth; ſtem decumbent." *Root* perennial. *Stems* about a foot long, branched, ſmooth. *Leaves* narrower, with ciliated or bearded ſheaths, and a ſmaller one within the other. *Flowers* with two petals; yellow, unguiculated and roundiſh, or kidney-ſhaped; the third ſmall, oval, ſeſſile, and of a pale colour. *Capſule* egg-ſhaped, two-valved, three-celled. *Seeds* in the upper cells, two, three, or four, roundiſh, ſmooth, umbilicated; but always barren and deſtitute of albumen; in the lower cell ſolitary, fertile, adnate to the valve on its whole length. A native of Africa. 3. C. *mollis.* Willd. 7. Lam. Ill. 600. Jacq. Collect. 3. 253. ic. rar. 293. "Leaves egg-ſhaped, petioled, villous; ſtem creeping." A native of South America. 4. C. *bengalenſis.* Linn. Sp. Pl. 3. Mart. 3. Lam. 3. Ill. 601. Willd. 3. (Ephemerum benghalenſe repens; Pluk. Alm. 135. tab. 27. fig. 3.) "Leaves egg-ſhaped, obtuſe; ſtem creeping." *Root* annual. *Stems* numerous, ſlightly villous, ſlender, branched. *Leaves* from an inch to an inch and half long, edged with very ſhort hairs, petioled above the ſheath; ſheath ciliated, marked with lines, ſpotted with purple. *Spathe* terminal, cowled, ſomewhat triangular, marked with lines. *Peduncles* within the ſpathe, two; one ſlender, longer, with a ſingle flower; the other thicker, channelled, bearing from two to four flowers, on jointed inflexed pedicels. *Petals* blue; ſmaller one paler. *Nectaries* yellow. A native of Bengal and Cochin-china. 5. C. *erecta.* Linn. Sp. Pl. 4. Mart. 4. Lam. 4. Ill. 602. Willd. 4. Dill. Elth. 91. tab. 77. fig. 88. "Leaves ovate-lanceolate; ſtem erect, ſcabrous, quite ſimple." *Root* perennial, fibrous. *Stems* a foot and half high, leafy. *Leaves* a little hirſute, but not hairy, except at the ſheath. *Flowers* pale blue; ſmaller petal very narrow, whitiſh and pellucid. *Capſules* roundiſh, obtuſely triangular, with three ſeeds. A native of Virginia.

** *Petals nearly equal.*

6. C. *virginica.* Linn. Sp. Pl. 5. Mart. 5. Lam. 5. Ill. 603. Willd. 5. (Ephemerum phalangoides; Pluk. Alm. 135. tab. 174. fig. 4.) "Leaves lanceolate, in ſhort petioles; bearded at the edge; ſtems erect." Nearly allied to the preceding, and perhaps, only a variety. *Root* perennial. *Stems* two feet high, ſimple, ſlightly villous. *Leaves* ſcabrous on the upper ſurface when rubbed from the baſe, pubeſcent underneath, narrowed near the ſheath. *Sheaths* nerved, ſomewhat pubeſcent, ciliated at the edge with reddiſh hairs. *Flowers* blue; the lower one on a ſhort pedicel; petals heart-ſhaped, quite entire. A native of Virginia. 7. C. *longicaulis.* Willd. 6. Jacq. ic. rar. 2. tab. 294. Collect. 3. p. 234. "Leaves linear-lanceolate, ſeſſile; ſheaths ciliated; ſtem decumbent." *Root* perennial. *Leaves* ſmoothiſh. *Pedicels* in pairs, filiform, jointed. A native of Caracas. 8. C. *hexandra.* Lam. 6. Ill. 604. Aubl. Guian. tab. 12. "Flowers hexandrous, in racemes." *Root* perennial. *Stems* three feet high or more, ſarmentous, climbing, bent at the joints. *Leaves* egg-ſhaped, acute, narrowed and petioled near the ſheath; ſheaths half an inch long, ciliated. *Flowers* blue; filaments ſhort and not villous, as in Tradeſcantia. 9. C. *tuberoſa.* Linn. Sp. 6. Mart. 6. Lam. 7. Ill. 605. Willd. 8. Dill. Elth. 94. tab. 79. fig. 90. Gært. tab. 15. fig. 2. Lam. tab. 35. fig. 2. "Leaves ſeſſile, ovate lanceolate, ſomewhat ciliated." *Root* perennial, conſiſting of ſeveral tubers ſomewhat like thoſe of ranunculus, or of common orpine (ſedum telephium), joining together at the top and forming a head, diminiſhing gradually downwards. *Stems* a foot high, weak, aſcending, branched at their baſe. *Leaves* villous underneath, ſmooth above; ſheath ſmooth, ſtriated, reddiſh, ſimply ciliated at the edge. *Flowers* blue, growing ſeveral together on ſlender peduncles. *Capſule* ovate-acuminate, ſomewhat depreſſed, two-valved, three-celled; upper valve, divided longitudinally into two cells; lower valve one-celled, a little concave above, convex below, cloſely adnate to the ſeed. *Seeds* in each of the upper cells two, tubercle wrinkled, ferruginous; in the lower cell, one, elliptical, ſmooth, lenticularly compreſſed, of a bay colour. Gært. A native of Mexico. 10. C. *barbata.* Lam. Ill. 606. "Leaves egg-ſhaped, ſeſſile; ſheaths bearded; ſtem creeping." A native of the iſland of Mauritius. 11. C. *longifolia.* Lam. Ill. 607. "Leaves lanceolate-linear; peduncles very long." A native of the iſland of Java. 12. C. *zanonia.* Linn. Sp. Pl. 7. Mart. 7. Lam. 8. Gært. tab. 15. fig. 4. Lam. Ill. tab. 35. fig. 4. (Zanonia; Plum. Gen. 38. Tradeſcantia zanonia; Willd. Swartz.) "Peduncles thickened; leaves lanceolate; ſheaths hairy at the edge; bractes in pairs." *Root* perennial. *Stem* about two feet high, cylindrical, jointed, ſmooth, branched towards the top. *Leaves* four or five inches long, about two broad, green and ſmooth above, ſlightly pubeſcent underneath when young, with purple-brown, or violet edges; ſheaths whitiſh-green, large. *Flowers* white; Lam. Sky-blue; Miller. *Fruit* berried, in an egg-ſhaped terminal raceme: berries falſe, dark-purple, formed of the corolla changed into a fleſhy ſucculent three-lobed ſubſtance which compleatly encloſes the capſule; capſule cylindric-egg-ſhaped, cruſtaceous, dotted in rows, teſtaceous, three-celled, opening at the tip into three parts. *Seeds* two, or one in each cell; in the cells which have two, angular, a little wrinkled, cinereous, with a ſmall pap on the ſide covering the embryo; in the cell which has only one, elliptical plano-convex, a little wrinkled about the edge, bearing the embryo on the middle of the back. Gært. A native of Cayenne, in South America. 13. C. *vaginata.* Linn. Mant. 177. Mart. 8. Lam. 9. Ill. 609. Willd. 9. "Leaves linear; flowers diandrous, ſheathed with an involucre." *Root* annual. *Stems* aſcending, numerous, ſomewhat ſcabrous. *Leaves* ſeſſile, acute. *Peduncles* terminal and axillary, elongated, ending in a ſtriated, lanceolate involucre, which is ſo convolute as to be almoſt cylindrical; calyx-leaves lanceolate, acute, coloured at the tip; petals oval, the length of the calyx; filaments of the nectary four, half the length of the ſtamens; nectaries linear; filaments of the ſtamens two, bearded, ſomewhat recurved, the length of the corolla; anthers yellow, marked with a black ſpot; ſtyle awl-ſhaped, ſomewhat recurved. Found by Koenig in the Eaſt Indies. 14. C. *nudiflora.* Linn. Mant. 177. Mart. 9. Lam. 10. Ill. 609. Willd. 10. "Peduncels capillary; leaves linear, without an involucre; flowers diandrous." *Root* annual. *Stem* about ſeven inches high, ſlender, nearly erect, decumbent at the baſe, ſomewhat ſcabrous. *Leaves* ſeſſile, acute; ſheath ſhort; edged with a few lax hairs. *Peduncles* for the moſt part terminal, from two to four together, accompanied by a very ſhort bracte. *Flowers* from four to ſix on each peduncle, naked, pedicelled; calyx-leaves ovate-lanceolate, acute, leſs than the corolla; petals three, egg-ſhaped, unequally diſtributed; the two lower ones moſt diſtant; filaments of the nectary three, half the length of the ſtamens, naked; nectaries deltoid; filaments of the ſtamens two, bearded, declining at the opening of the corolla; ſtyle declining. Found by Koenig in dry paſtures of the Eaſt Indies. 15. C. *cucullata.* Linn. Mant. 176. Mart. 11. Lam. 11. Ill. 611. Willd. 11. (C. nervoſa; Burm. ind. 18. tab. 7. fig. 3.) "Leaves egg-ſhaped; involucres cowled, turbinate." *Root* annual. *Stem* ſeven inches high, creeping at the baſe, and ſending out filiform roots. *Leaves* nerved, petioled; ſheaths wider than the ſtem; ciliated at the edge with diſtant, ſpreading, briſtle-ſhaped hairs; involucres terminal, truncated, many-flowered, entirely coaleſcent by the ſide. *Flowers* peduncled, minute. A native of the Eaſt Indies. 16. C. *japonica.* Thunb. in Linn. Tranſ. 2. 332. Mart. 12. Willd. 12. "Leaves ovate-lanceolate, undulated; ſtem erect, angular,

hairy; flowers panicled." *Stem* a foot high, furrowed, panicled at the top. *Leaves* alternate, ſheathing, acute, ſmooth; lower ones three inches long; upper ones about an inch. A native of Japan. 17. C. *ſpirata*. Linn. Mant. II. 176. Hort. Kew. 77. (C. bracteolata; Lam.?) "Leaves lanceolate: flowers panicled." Linn. "Leaves lanceolate-linear, undulated, ſomewhat curled; peduncles panicled, furniſhed with ſmall bractes, half-embracing the ſtem." Lam. *Root* annual. *Stem* creeping, aſcending, ſomewhat ſcabrous; Linn. *Stem* ſix or ſeven inches long, very ſlender, bent at the joints, almoſt ſmooth, leafy, branched; Lam. *Leaves* lanceolate, ſheathing, very minutely ſerrated; upper leaf cordate-lanceolate; ſheaths ciliated at the edge. Linn. *Leaves* narrow; ſheaths ſhort, ciliated; Lam. *Flowers* ſmall, bluiſh; Lam. *Panicle* terminal, divaricated, with ſmall ſheathing bractes; Linn. Lam. *Peduncles* capillary, compound; Lam. *Calyx* three-leaved; leaves ovate-lanceolate, concave; Lam. *Petals* three, equal, orbicular-egg-ſhaped; Linn. *Petals* three, egg-ſhaped, a little longer than the calyx. Lam. *Filaments* of the *ſtamens* three, bearded, naked above the middle. Linn. Almoſt entirely naked. Lam. *Filaments* of the *nectary* three, ſomewhat ciliated at the ſides. Corpuſcles cruciform, globular at the tips, whitiſh; Linn. corpuſcles yellow; Lam. *Style* and *ſtigma* ſpirally convolved, and evolved variouſly; Linn. *Style* permanent, a little ſpirally twiſted when the flower is paſt; Lam. Found by Koenig in moiſt ground, by the ſide of rivulets in the Eaſt Indies; communicated to La Marck from the Eaſt Indies by Sonnerat. La Marck ſeems to have no good reaſon to doubt the identity of his plant with that of Linnæus.

Obſ. It is evident from the above deſcriptions, that this genus, as it now ſtands, is a very anomalous one. C. hexandra, if it had bearded filaments, would unqueſtionably be a tradeſcantia. C. vaginata, nudiflora, and ſpirata, approach that genus, by their partially bearded filaments, but differ in the number of ſtamens; the firſt two have the additional anomaly of being diandrous, without a correſponding diminution in the number of the other parts. Linnæus, when he took up theſe three ſpecies, in his ſecond Mantiſſa, ſeems to have forgotten, or to have diſcarded, his original idea with reſpect to the flower; for he there attributes to it, not a ſix petalled corolla, but a three-petalled one, with a proper three-leaved calyx. Gærtner is of opinion that commelina and tradeſcantia are one truly natural genus.

COMMELINA *axillaris et criſtata*. Linn. See TRADESCANTIA.

Propagation and Culture. All the ſpecies are propagated by ſeeds. If the ſeeds of C. communis, which is an annual, be ſown upon a warm border of light earth in the autumn, they will come up early in the ſpring and ripen their fruit. The roots of C. africana ſend out offſets, by which the plant is eaſily propagated; but they will ſeldom live through the winter in the open air. The other ſpecies are tender, and muſt be ſown in a moderate hot-bed in the ſpring; tranſplanted to a freſh hot-bed, when they are two inches high; and in June, again tranſplanted into a warm border of light earth. C. tuberoſa may be preſerved, if planted in pots, and placed in the bark-ſtove in autumn: or its roots may be taken out of the ground in the autumn, kept in a warm place during the winter, and planted again in the ſpring; they will be more forward and ſtronger if placed on a hot-bed.

COMMEMORATION, the remembrance of any one; or ſomething done in honour of a perſon's memory.

Among the Romaniſts, it is a practice for dying perſons to leave a legacy to the church, for the rehearſing ſo many maſſes in commemoration of them.

The euchariſt is a commemoration of the ſufferings of Jeſus Chriſt.

COMMEMORATION is alſo the name of two religious feaſts, otherwiſe called *all-ſaints* and *all-ſouls*. The occaſion of their inſtitution is variouſly related. See the articles.

COMMEMORATION *of Handel*, in *Muſic*. In order to record an event ſo honourable to a liberal art, we ſhall draw our information from the hiſtory of that art, and from the account itſelf of the commemoration written expreſsly at the time, and publiſhed in 4to. by the ſame author, an attentive auditor of all the performances, whoſe ſenſations and memory were more freſh then than at the diſtance of 22 years.

In the "Hiſtory of Muſic," vol. iv. p. 518. it is ſaid, that "The year 1784 was rendered a memorable æra in the annals of muſic, by the ſplendid and magnificent manner in which the birth, genius, and abilities of Handel, were celebrated in Weſtminſter Abbey and the Pantheon, by five performances of pieces ſelected from his own works, and executed by a band of more than 500 voices and inſtruments in the preſence and under the immediate auſpices of their majeſties and the firſt perſonages in the kingdom. This event ſo honourable to the art of muſic and an illuſtrious artiſt, and ſo worthy of a place here, having been minutely recorded already in a diſtinct work, *viz.* "Account of them uſical performances in commemoration of Handel," by the author of this hiſtory, written and publiſhed for the benefit of the muſical fund; an eſtabliſhment which his majeſty having ſince deigned to honour with his patronage, the members and guardians have been permitted to incorporate themſelves under the title of Royal Society of Muſicians: We ſhall only add, that this celebration has been ſince eſtabliſhed into an annual muſical feſtival for the benefit of the fund, in which the number of performers, and perfection of the performances, as well as favour of the public, have continued to increaſe. In 1785, the vocal and inſtrumental band amounted to ſix hundred and ſixteen. In 1786, to ſeven hundred and forty-one; and in 1787, to eight hundred and ſix vocal and inſtrumental performers."

And in the ſame "Hiſtory of Muſic," at the end of the ſame vol. the author tells us, that "The commemoration of Handel, in 1784, having been crowned with a ſucceſs equally honourable to that great artiſt and to the nation, ſimilar performances have ſince been annually repeated, to ſtill more numerous audiences, for charitable purpoſes, in Weſtminſter-Abbey, under the title of a "Grand Muſical Feſtival." In 1787, the band of vocal and inſtrumental performers amounted to eight hundred and ſix muſicians, excluſive of the principal ſingers, conſiſting of twenty-two, with Madame Mara, Rubinelli, Harriſon, and Morelli at their head. And ſuch is the ſtate of practical muſic in this country, that the increaſe of performers, inſtead of producing confuſion, as might have been expected, has conſtantly been attended with ſuperior excellence of execution; as experience, the beſt of all teachers, has ſo guided the zeal of the directors, and the ſcience of the conductor and leader of this great enterprize, that a certain road to full perfection in every department ſeems to have been attained.

Though this celebration happened ſo recently, and is ſo well known as ſcarcely to need being mentioned here for the information of the preſent race, among muſical articles; yet as our plan extends to hiſtory and biography, as well as definitions and ſcientific explanations, a record of a muſical event of ſuch magnitude ſeems neceſſary for the information of diſtant times, if we may dare hope to reach them. The origin and progreſs of the plan, as related in the introduction to the printed narrative, dedicated by permiſſion to the king, is the following.

" It was in the year 1783, that the idea of this great enterprize was conceived in a converſation between lord viſcount Fitzwilliam, the late ſir Watkin Williams, and Joah Bates, late commiſſioner of the victualling office, on obſerving how much more London abounded with great muſicians, vocal and inſtrumental, foreigners and natives, than any other city in Europe: but ſo diſunited and diſperſed at the operas, oratorios, theatres, and public and private concerts, that they can never be heard in the aggregate, nor can the effects which may be produced by ſuch a united band as our capital could furniſh, ever be known, unleſs ſome plan was formed of a public periodical occaſion for collecting and conſolidating them into one band; by which means a performance might be exhibited on ſo grand and magnificent a ſcale as no other part of the world could equal. The birth and death of Handel naturally occurred to three ſuch enthuſiaſtic admirers of that great maſter, and it was immediately recollected, that the next (now the preſent) year, would be a proper time for the introduction of ſuch a cuſtom: as it formed a complete century ſince his birth, and an exact quarter of a century ſince his deceaſe.

The plan was ſoon after communicated to the governors of the Muſical Fund, who approved it, and promiſed thier aſſiſtance. It was next ſubmitted to the directors of the concert of Ancient Muſic, who, with an alacrity which does honour to their zeal for the memory of the great artiſt Handel, voluntarily undertook the trouble of managing and directing the celebrity. At length, the deſign coming to the knowledge of the king, it was honoured with his majeſty's ſanction and patronage. Weſtminſter Abbey, where the bones of the great muſician were depoſited, was thought the propereſt place for the performance; and application having been made to the biſhop of Rocheſter for the uſe of it, his lordſhip, finding that the ſcheme was honoured with the patronage of his majeſty, readily conſented; only requeſting, as the performance would interfere with the annual benefit for the Weſtminſter Infirmary, that part of the profits might be appropriated to that charity as an indemnification for the loſs it would ſuſtain. To this the projectors of the plan acceded; and it was afterwards ſettled, that the profits of the firſt day's performance ſhould be equally divided between the muſical fund and the Weſtminſter Infirmary; and thoſe of the ſubſequent days be ſolely applied to the uſe of that fund which Handel himſelf ſo long helped to ſuſtain, and to which he not only bequeathed a 1000*l.*, but which almoſt every muſician in the capital annually contributes his money, his performance, or both, to ſupport.

Impreſſed with a reverence for the memory of Handel, no ſooner was the project known, but moſt of the practical muſicians in the kingdom eagerly manifeſted their zeal for the enterpriſe; and many of the moſt eminent profeſſors, waving all claims to precedence in the band, offered to perform in any ſubordinate ſtation, in which their talents could be moſt uſeful."

" By the latter end of February, the plan and neceſſary arrangement were ſo far digeſted and advanced, that the directors ventured to inſert in all the newſpapers, the following advertiſement.

Under the Patronage of His Majeſty,
In Commemoration of Handel, who was buried in
Weſtminſter Abbey, on the 21ſt of April, 1759.

On Wedneſday the 21ſt of April next, will be performed in Weſtminſter Abbey, under the management of the

Earl of Exeter
Earl of Sandwich
Viſcount Dudley Ward
Viſcount Fitzwilliam
Lord Paget
Right Hon. H. Morrice
Sir W. Williams Wynn, Bart.
Sir Richard Jebb, Bart.

Directors of the concert of Ancient Muſic;

Some of the moſt approved pieces of ſacred muſic, of that great compoſer.

The doors will be opened at 9 o'clock, and the performance will begin preciſely at twelve.

And on the evening of the ſame day, will be performed, at the Pantheon, a grand miſcellaneous concert of vocal and inſtrumental muſic; conſiſting entirely of pieces ſelected from the works of Handel.

The doors will be opened at 6 o'clock, and the concert will begin exactly at eight.

And on Saturday morning, April 24th, will be performed, in Weſtminſter Abbey, the ſacred oratorio of the Meſſiah.

Such is the reverence for this illuſtrious maſter, that moſt of the performers in London, and a great many from different parts of the kingdom, have generouſly offered their aſſiſtance; and the orcheſtra will conſiſt of at leaſt 400 performers, a more numerous band than was ever known to be collected in any country, or on any occaſion whatever. The profits ariſing from the performances, will be applied to charitable purpoſes.

In order to render the band as powerful and complete as poſſible, the trombone, ſacbut, or double curtle, and double kettle drums, were ſought and their uſe revived.

In preparing Weſtminſter Abbey for the reception of their majeſties and the royal family, as well as the archbiſhops and biſhops, judges, great officers of ſtate, and principal nobility and gentry in the kingdom, to the amount of three or four thouſand, Mr. James Wyatt, the admirable architect of the ill-fated Pantheon, furniſhed the elegant drawings for the orcheſtra, throne, and galleries.

As this commemoration is not only the firſt inſtance of a band of ſuch magnitude being aſſembled together, but of any band, at all numerous, performing in a ſimilar ſituation, without the aſſiſtance of a manu-ductor, to regulate the meaſure, the performances in Weſtminſter Abbey may be ſafely pronounced, no leſs remarkable for the multiplicity of voices and inſtruments employed, than for accuracy and preciſion. When all the wheels of that huge machine, the orcheſtra, were in motion, the effect reſembled clock-work in every thing, but want of feeling and expreſſion.

And, as the power of gravity and attraction in bodies are proportioned to their maſs and denſity, ſo it ſeems as if the magnitude of this band had commanded and impelled adheſion and obedience, beyond that of any other of inferior force. The pulſations in every limb, and ramifications of veins and arteries in an animal, could not be more reciprocal, iſochronous, and under the regulation of the heart, than the members of this body of muſicians under that of the conductor and leader. The totality of ſound ſeemed to proceed from one voice, and one inſtrument; and its powers produced, not only new and exquiſite ſenſations in judges, and lovers of the art, but were felt by thoſe who never received pleaſure from muſic before.

This celebration was at firſt deſigned to be extended to no more than two performances on the ſame day: one at noon in Weſtminſter Abbey, for ſacred muſic; and the other in the evening of the ſame day at the Pantheon, for ſecular compoſitions, ſelected from the operas and miſcellaneous works of the hero whoſe apotheoſis was the efficient cauſe of this extraordinary undertaking. But being countenanced by his majeſty, the directors of the concert of ancient muſic, the governors of the muſical fund, and eagerly patronized by the public in general, while the plan was digeſting, it determined the projectors, at the inſtigation of his majeſty, to have three performances. The firſt and third in the morning, at Weſtminſter Abbey, and the ſecond at the Pantheon.

Theſe performances having given ſuch entire ſatisfaction to all that were preſent, and becoming, of courſe, the general ſubject of diſcuſſion and praiſe, excited a great deſire in all lovers of muſic, and even of ſplendid ſpectacles, who were abſent, to be enabled to judge and ſpeak of tranſactions ſo memorable, from the conviction of their own ſenſes. But even theſe were not more eager in wiſhing there might be a repetition of the performances, than thoſe who had already attended them. Luckily for all parties, the wiſhes of their majeſties coincided with thoſe of their ſubjects; and as the ſcaffolding was ſtill ſtanding, and the band not yet diſperſed, two more opportunities were given for the diſplay of Handel's wonderful powers, and the gratification of public curioſity.

The fourth day was ſupplied with a well choſen ſelection of Handel's moſt grand and captivating compoſitions, from his oratorios and anthems; and on the fifth, that ſublime production, the Meſſiah, was repeated; and though it had been performed in the Abbey but a week before, in ſo perfect and magnificent a manner, that no rehearſal, previous to its repetition, was neceſſary to the band; yet, to gratify the wiſhes of many timid and infirm lovers of muſic, who dreaded the croud that was likely to be aſſembled at a public performance, as well as to raiſe money for charitable purpoſes, another rehearſal would certainly have been announced, if it had not been prevented from taking place by the celebration of his majeſty's birth-day, on which occaſion there was a certainty that the chief part of the performers and company would be engaged.

Thoſe who attended this day's commemoration at the Abbey were, ſeemingly, of a higher claſs than had yet appeared there; ſo that though the croud was ſomewhat leſs than at the preceding performance of the ſame oratorio, the exhibition was more ſplendid. Indeed, as a ſpectacle, it was ſo magnificent to the ſight, and, as a muſical performance, ſo mellifluous and grateful to the ear, that it will be difficult for the *mind's eye* of thoſe who were abſent, to form an adequate idea of the ſhow, or the *mental ear* of the ſound, from deſcription. Every one preſent muſt have found full employment for the two ſenſes which afford us the moſt refined pleaſure; as it is from the eye and the ear that intellect is fed, and the mind furniſhed with its beſt intelligence.

At the firſt performance of the Meſſiah, his majeſty expreſſed a deſire to the earl of Sandwich of hearing the moſt truly ſublime of all choruſſes, "Allelujah! for the Lord God omnipotent reigneth," a ſecond time; and this gracious wiſh was conveyed to the orcheſtra, by the waving of his lordſhip's wand. At this ſecond performance of that matchleſs oratorio, his majeſty was pleaſed to make the ſignal himſelf, with a gentle motion of his right hand, in which was the printed book of the words, not only for the repetition of this, but of the final chorus, in the laſt part, to the great gratification of all his happy ſubjects preſent; and, perhaps, the ſubjects of no ſovereign prince on the globe were ever before ſo delighted with the effects of a royal mandate.

Thus ended the fifth and laſt of the performances for this memorable celebration; and ſo great and perfect was the pleaſure which the audience had received, that thoſe who had attended all the five exhibitions ſeemed moſt to regret this final cloſe.

The whole receipts at the five performances of this moſt ſplendid and magnificent celebration amounted to 12,736*l.* 12*s.* 10*d.* Of which, after all diſburſements for building, band, and other incidental expences, to the amount of 5736*l.* 12*s.* 10*d.*, 6000*l.* remained for the fund of the ſociety of decayed muſicians, and 1000*l.* for the Weſtminſter hoſpital.

At the end of the printed account of the firſt year's *Commemoration of Handel*, is added in the Appendix, a "Hiſtory of the Riſe and Progreſs of the Fund for the Support of decayed Muſicians and their Families, eſtabliſhed in 1738," which has been ſince laudably imitated by other profeſſions, and in other countries; and it appeared in 1784, after theſe performances, that by the great acceſſion to the fund from the commemoration, its capital became a ſerious and weighty concern, amounting to upwards of 22,000*l.*, in South-ſea annuities and three per cents.; which realizes and aſcertains an income of 678*l.* a year, excluſive of benefits or ſubſcription.

The path therefore which the governors and court of aſſiſtants have now to purſue, is perfectly plain and pleaſant; the power of alleviating diſtreſs and miſery, of feeding the hungry, clothing the naked, and adminiſtering comfort to age and infirmities, is placed in their hands, without the trouble of providing the means.

COMMENASA, in *Ancient Geography*, a river of Aſia, according to Arrian, who ſays that it ran into the Indus.

COMMENDAM, in the *Canon Law*, expreſſes the charge, truſt, and adminiſtration of the revenues of a benefice, given to a layman to enjoy, by way of depoſitum, for the ſpace of ſix months, in order to its being repaired, &c. or to another biſhop, or eccleſiaſtic, to perform the paſtoral offices thereof, till ſuch time as the benefice is provided of a regular incumbent. See BENEFICE.

Anciently, the adminiſtration of vacant biſhoprics belonged to the neareſt neighbouring biſhop; which continued to be practiſed between the archbiſhopric of Lyons, and the biſhopric of Autun: on this account they were called *commendatory biſhops*.

This cuſtom appears to be very ancient: St. Athanaſius ſays of himſelf, according to Nicephorus, that there had been given him in *commendam*, i. e. in adminiſtration, another church beſides that of Alexandria, whereof he was ſtated biſhop.

The care of churches, it ſeems, which had no paſtor, was committed to a biſhop, till they were provided with an ordinary: the regiſter of pope Gregory I. is full of theſe commiſſions, or commendams, granted during the abſence or ſickneſs of a biſhop, or the vacancy of a ſee. Some ſay, that pope Leo IV. firſt ſet the modern commendams on foot, in favour of eccleſiaſtics who had been expelled their benefices by the Saracens; to whom the adminiſtration of the vacant churches was committed for a time, in expectation of their being reſtored: though St. Gregory is ſaid alſo to have uſed the ſame, while the Lombards deſolated Italy.

In a little time, the practice of commendams became exceedingly abuſed; and the revenues of monaſteries were given to laymen for their ſubſiſtence. The biſhops alſo procured ſeveral benefices, or even biſhoprics, in commendam, which ſerved for a pretext for holding them all without directly violating the canons. Part of the abuſe has been retrenched; but the uſe of commendams is ſtill retained, as an expedient to take off the incompatibility of the perſon, by the nature of the benefice.

When a parſon is made biſhop, his parſonage becomes vacant; but if the king by ſpecial diſpenſation give him power to retain his benefice, notwithſtanding his promotion, he ſhall continue parſon, and is ſaid to hold it *in commendam;* but this muſt be done before conſecration, for afterwards it comes too late, becauſe the benefice is then abſolutely void. There are ſeveral ſorts of commendams founded on the ſtat. 25 Hen. VIII. cap. 21. as a *commendam ſemeſtris,* which is for the benefit of the church, without any regard to the commendatary, being only a proviſional act of the ordinary, for ſupplying the vacation of 6 months, in which time the patron is to preſent his clerk, and only implies a ſequeſtration of the cure and fruits till the clerk is preſented: *commendam retinere,* by means of which a biſhop retains benefices on his preferment, which has operated for a certain number of years, or even as long as the *commendatary* lived, and continued biſhop; and theſe commendams are granted on the king's mandate to the archbiſhop, expreſſing his conſent, which continues the incumbency, ſo that there is no occaſion for inſtitution: a *commendam recipere,* which is to take a benefice *de novo,* in the biſhop's own gift, or of ſome other patron, whoſe conſent is obtained; and for life, when it is equal to a preſentation, without inſtitution, or induction. But all diſpenſations beyond 6 months were only permiſſive at firſt, and granted to perſons of merit; the *commendam retinere* is for one or two years, &c. and ſometimes for three or ſix years, and doth not alter the eſtate which the incumbent had before; and this, as long as the commendatary ſhould live and continue biſhop, hath been thought good. Vaugh. 18. The *commendam recipere* muſt be for life, as other parſons and vicars enjoy their benefices; and as a patron cannot preſent to a full church, ſo neither can a *commendam recipere* be made to a church that is then full. Show. 414.

A benefice cannot be *commended* by parts, any more than it may be preſented unto by parts; ſo that one ſhall have the glebe, another the tythes, &c. Nor can a commendatary have a *juris utrum,* or take to him and his ſucceſſors, ſue or be ſued, in a writ of annuity, &c. But a *commenda perpetua* may be admitted to do it. 11 Hen. IV. Compl. Incumb. 360. (See Nelſ. Abr. 454.)

Theſe commendams are now in fact ſeldom or never granted to any but biſhops; and in that caſe the biſhop is made commendatary of the benefice while he continues biſhop of ſuch a dioceſe, as the object is to make an addition to a ſmall biſhopric; and it would be unreaſonable to grant it to a biſhop for life, who might afterwards be tranſlated to one of the vacant ſees.

COMMENDAM, in popiſh countries, is a real title of a regular benefice; as an abbey, or priory given by the pope to a ſecular clerk, or even to a layman, with power to diſpoſe of the fruits thereof during his life.

No benefice that has a cure of ſouls, i. e. no parſonage, or biſhopric, can be given *in commendam.* This practice being entirely contrary to the canons, none but the pope, who has a power of diſpenſing with the canons, can confer it.

When the commendam becomes vacant by the death of the *commendatary,* it is not eſteemed vacant by his death; but as it was before the commendam was granted: that making no alteration in the thing: yet the pope gives the ſame benefice in commendam again, by a privilege which he ſtill continues.

By the pope's bulls, a *commendatary* abbot has the full authority of the regular abbot to whom he is ſubſtituted. For this reaſon, the bulls expreſsly require, that he be a prieſt; or, that if he have not yet attained the age of prieſthood, he ſhall take orders as ſoon as he has. But this is a mere formality, or matter of ſtyle, the thing is never executed.

Indeed, the ſpiritual direction of the abbey, while it is *in commendam,* is lodged wholly in the clauſtral priors.

The commendatary abbots have not any authority over the religious *in ſpiritualibus:* they even cannot either appoint or ſet aſide the clauſtral priors, who are nominated in the bulls the adminiſtrators of the ſpiritualities; in which, however, this reſtriction is added, viz. till the abbot arrive at the age of twenty-five years, to aſſume the prieſthood.

The popes grant benefices *in commendam,* not only to clerks, by diſpenſing with their age, and other qualifications required; but they alſo diſpenſe with the clericate even in children yet in the cradle, till they become of age to take the tonſure: it being ſufficient to obtain a bull, that it be repreſented at Rome, that the child is deſtined for the eccleſiaſtic ſtate. In this caſe there is an OECONOMUS, or ſteward, appointed to take care of the temporal concerns.

COMMENDATARY, a perſon who holds a church living or preferment *in commendam.*

COMMENDATARY *Letters,* are ſuch as are written by one biſhop to another in behalf of any of the clergy, or others of his dioceſe travelling thither; that they may be received among the faithful; or that the clerk may be promoted; or neceſſaries may be adminiſtered to others, &c. Several forms of theſe letters may be ſeen in our hiſtorians; as in Bede, lib. ii. cap. 18.

COMMENDATUS, one that lives under the protection of a great man.

Commendati homines were perſons who, by a voluntary homage, put themſelves under the protection of any ſuperior lord; for ancient homage was either predial, due for ſome tenure, or perſonal, which was by compulſion, as a ſign of neceſſary ſubjection; or voluntary, with a deſire of protection. And thoſe who by voluntary homage put themſelves under the protection of any men of power, were ſometimes called *homines ejus commendati,* ſometimes only *commendati,* as often occurs in Domeſday. *Commendati dimidii* were thoſe who depended on two ſeveral lords, and paid one half of their homage to each; and *ſub-commendati,* were like under-tenants, under the command of perſons who were dependants themſelves on a ſuperior lord. There were alſo *dimidii ſub-commendati,* who bore a double relation to ſuch depending lords. Domeſday. This phraſe ſeems to be ſtill in uſe, in the uſual compliment, *commend* me to ſuch a friend, &c. which is to let him know I am his humble ſervant. Spelm. of Feuds, cap. 20.

COMMENDO, called alſo *Commani, Kommani, Agueſto,* and *Guaffo,* in *Geography,* a kingdom of Africa, on the Gold coaſt, bordered on the weſt by the countries of Jabi and Jaben, on the north-weſt by Adom, by Ambrambo on the north; on the eaſt, by a little republic lying between Commendo and Fetu, called Addena, or Elmina; and by the ocean on the ſouth. The dimenſions are about five miles along the ſea-coaſt, and about as many up the country. In the centre, on the ſtrand, ſtands Little Commendo, or Commani, called by the negroes Ekki Tekki, having cape Aldea das Terras on the weſt, and Ampani on the eaſt, with ſome ſmall hamlets in the intermediate ſpaces. Commendo had formerly been a part of Saba and Fetu, but of late years it has been erected into a ſeparate monarchy. The chief city, or reſidence of the king, is called "Guaffo," which is large and well inhabited, containing no leſs than 400 houſes, and ſituated on high ground, at the diſtance of four miles from

Little Commendo; the Dutch diſtinguiſh both by the name of Great and Little Commendo. This kingdom produces but little rice; nevertheleſs, the vallies are no leſs fertile than agreeable, and the hills covered with wood, which affords a very delightful proſpect. Behind Little Commendo, the land riſes by a gentle aſcent into little hills, beautifully ſheltered with woods of a perpetual verdure; and at the bottom are meadows and plains diſpoſed in the moſt agreeable manner, and abounding with various kinds of fruit-trees. The natives are warlike, and ſo numerous, that in this little kingdom, the ſovereign is able to raiſe an army of 20,000 men. His ordinary body-guard is compoſed of 500 ſtout fellows, well armed, reſolute, and loyal. It has been ſaid that Commendo abounds in gold mines, but that the king, for fear of exciting the avarice of the Europeans, prohibits the working of them. This country is divided into two diſtinct provinces. We ſhall content ourſelves with deſcribing Little Commendo. This province is called by the Portugueſe Aldea das Terras, and by the natives Ekki Tekki. The town is ſaid to contain at leaſt 100 houſes. It is ſituated on the banks of a fine rivulet, that empties itſelf into the ſea on the ſouthward, which forms a kind of canal, or little oblong harbour for canoes. The N.E. ſide of the town, where the French had formerly a ſettlement, is bordered by little hills, at the foot of which lie fine rich meadows and paſture, as well as fertile fields, every where interſperſed with groves of fruit-trees. Little Commendo, which was once a place of great note, and one of the fineſt towns in Guinea, has ſince exhibited only the remains of a town deſtroyed by fire, and the well peopled ruins of a once flouriſhing and great city. The natives of Little Commendo are in general turbulent, cunning, and deceitful; much addicted to lying and ſtealing. Their employment conſiſts either in fiſhing or in commerce, and their neighbours employ them as brokers and factors, particularly the people of Akamen, who carry on a conſiderable trade. Every morning 70 or 80 large canoes may be ſeen upon the coaſt fiſhing, or trading with the European ſhipping in the road. About the middle of the day they put to ſhore when the ſouth-weſt winds begin to blow, both for facility of unloading, and for ſecuring a market for their cargoes, either at Great or Little Commendo, where the inland negroes aſſemble with the commodities of their principal countries. No markets on earth are better ſupplied with all ſorts of grain, roots, fruits, pulſe, and fiſh, than theſe, nor at a more reaſonable price. Here the Engliſh and Dutch have forts. Next to Cape Coaſt, the Engliſh fort is ſaid to be the principal which they poſſeſs in Guinea, at leaſt on the Gold Coaſt. The Dutch fort of Wodenbourgh, lies at the diſtance of a muſket ſhot, and was built in the year 1688. N. lat. 4° 54′. E. long. 0° 34′.

The principal commodities for which there is a demand by the negroes of Commendo, are glaſs beads, braſs bells, and buttons, long linen cloths and woollen ſtuffs. They are very dextrous in the adulteration of gold, and the practice is very common. When the people of Commendo are at war, they have uſually a ſlave-market at Little Commendo, for the more quick diſpatch of their buſineſs. Here alſo they keep quantities of gold in the hands of certain agents employed to carry on trade, while the reſt are fighting the enemy in the field. The gold trade, however, is not very conſiderable.

COMMENDONE, Gianfrancesco, in *Biography*, an eminent prelate in the church of Rome, was born at Venice in 1524, and began, at the early age of ten years, to compoſe verſes. He purſued his ſtudies at Padua, and in the year 1550, he was introduced to pope Julius III., by whom he was made chamberlain, and afterwards employed on public buſineſs. In 1553, he accompanied the legate cardinal Bandino to Flanders, and from thence he was diſpatched ſecretly to England, to enquire into the ſtate of religion under queen Mary. Paul IV. made him biſhop of Zant, and commiſſioned him to excite the different ſtates of Italy to unite with him in a common league. By Pius IV. he was raiſed to the office of cardinal in 1565, while he was nuncio in Poland. He was employed in various other miſſions to foreign ſtates, and in all theſe he acted with zeal for his church, and executed whatever was committed to his charge with the utmoſt diſpatch and fidelity. Under Gregory XIII. he was proſecuted by the imperial faction for having too great a partiality towards France; his own party was, however, ſo ſtrong, that he was not only acquitted, but upon a dangerous illneſs of the pope, it was projected to raiſe him to the papal crown. The pope, by recovering his health, diſappointed his expectations, and Commendone himſelf died at Padua, in December, 1584. He is not celebrated as an author, having left behind him only ſome Latin poems, among thoſe of the Academy of Occulti, of which he was the zealous patron, and ſome letters inſerted in the notes to thoſe of Julio Poggiano. Commendone was reckoned one of the ableſt politicians of his own time, a man of great learning, and a friend to literature. He cultivated an intimate friendſhip with many of the moſt eminent ſcholars in Italy, and to him were addreſſed ſome letters of Annibal Caro. Gen. Biog.

Commensurable *Quantities*, in *Geometry*, are ſuch as have ſome common aliquot part, or which may be meaſured or divided without leaving a remainder, by ſome meaſure or diviſor, called their common meaſure. Thus, a foot and a yard are commenſurable; there being a third quantity which will meaſure each, viz. an inch; which taken 12 times makes a foot, and 36 times a yard.

Commenſurables are to each other as one rational whole number to another. In incommenſurables it is otherwiſe. The ratio of commenſurables, therefore, is rational; that of incommenſurables irrational: hence, alſo, the exponent of the ratio of commenſurables is a rational number.

Commensurable *Numbers*, in *Arithmetic*, whether integers or fractions, are ſuch as have ſome other number which will meaſure or divide them without any remainder. Thus, 6 and 8, both divided by 2, are reſpectively commenſurable numbers: $\frac{2}{3}$ and $\frac{3}{4}$, or $\frac{8}{12}$ and $\frac{9}{12}$, are commenſurable fractions, becauſe the fraction $\frac{1}{6}$ or $\frac{1}{12}$ will meaſure them both; and in this ſenſe all fractions may be ſaid to be commenſurable.

Commensurable *in Power*. Right lines are ſaid to be commenſurable in power, when their ſquares are meaſured by one and the ſame ſpace, or ſuperficies.

Commensurable *Surds*, are ſuch ſurds as, being reduced to their leaſt terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational: ſuch are $3\sqrt{2}$ and $2\sqrt{2}$ being one to the other as 3 to 2. See Surd.

COMMENTACULA, among the Romans, the rod which the flamens carried in their hands when going to ſacrifice.

COMMENTARIENSIS, in *Ancient Military Language*, the perſon who was gaoler of the ſoldiers' priſon among the Romans, and kept its regiſters. He was ſubject to the "triumviri capitales."

COMMENTARY, or Comment, a gloſs, or interpretation, affixed to ſome ancient, obſcure, or difficult author, to render him more intelligible, or to ſupply what he has left undone. The biblical ſtudent may find ſome judicious and uſeful remarks on *commentators*, or thoſe who have written commentaries on the Sacred Scripture, in Mr. Locke's Preface

face to his Paraphraſe and Notes on the Epiſtles of St. Paul.

COMMENTARY is alſo uſed for a ſort of hiſtory, written by a perſon who had a chief hand in the tranſactions related.

Such are the commentaries of Cæſar, of Sleidan, Montluc, &c.

The word is alſo uſed for certain books written on ſome particular ſubject: Kepler has an excellent book of commentaries on Mars, containing obſervations on the motion of that planet.

COMMEQUIERS, in *Geography*, a town of France, in the department of the Vendée, 15 miles N. of Sables d'Olonne.

COMMERAGH, or CUMMERAGH, the name of a high ridge of mountains which lie between Dungarvan and Clonmell, in the county of Waterford, Ireland. On the ſides of this chain, ſays Dr. Smith, are many horrid precipices and ſteep declivities, and the vallies are full of large fragments intermixed with ſand and gravel. On the tops of moſt of them are alſo large heaps of ſtones. Smith's Waterford.

COMMERCE, the interchange of commodities, or the diſpoſal of produce of any kind for other articles, or for ſome repreſentative of value for which other articles can be procured, with the view of making a profit by the tranſaction. The term is uſually reſtricted to the mercantile intercourſe between different countries; the internal dealings between individuals of the ſame country, either for the ſupply of immediate conſumption, or for carrying on manufactures, being more commonly denominated *trade*.

The mutual convenience of an exchange of commodities, muſt have been evident almoſt as ſoon as any part of mankind had acquired an idea of diſtinct property; the difficulty of communication between different countries muſt, however, have long rendered commercial intercourſe very limited and uncertain. The dangers attending long journies induced thoſe who engaged in trading to diſtant parts, to aſſociate together for mutual aſſiſtance and defence; and theſe companies of merchants, or caravans, were well adapted for the improvement of commerce, from the information which the individuals compoſing them would communicate to each other, and the connections they might occaſionally form. In the book of Geneſis, mention is made of the companies or caravans of Iſhmaelite merchants trading in ſpices from Gilead into Egypt; to one of whom Joſeph was ſold, about 620 years after the flood. But this mode of communication between different countries was inſufficient for the enterpriſing ſpirit of commercial adventurers; remote countries cannot convey their commodities by land to thoſe places where, on account of their rarity, they are moſt deſired, and conſequently become moſt valuable. It was not till ſome progreſs had been made in the art of navigation, that the power was acquired of tranſporting with facility the ſuperfluous ſtock of one part of the earth to ſupply the wants of another part, and that the active ſpirit of commerce could extend its multifarious concerns to all the known parts of the globe.

The Egyptians, ſoon after the eſtabliſhment of their monarchy, are ſaid to have opened a trade between the Arabian Gulph or Red Sea, and the weſtern coaſt of the great Indian continent. The commodities which they imported from the eaſt, were carried by land from the Arabian Gulph to the banks of the Nile, and conveyed down that river to the Mediterranean: but the maxims and manners of Egypt were inimical to commerce, and this profitable traffick ſoon declined.

The ſituation and circumſtances of the Phenicians naturally led them to look to commerce as the only ſource from which they could derive opulence or power; and accordingly, the foreign trade carried on by them, particularly from Sidon and Tyre, became more extenſive and important than that of any ſtate in the ancient world. Their ſhips not only frequented all the ports in the Mediterranean, but they were the firſt who ventured beyond the ancient boundaries of navigation, and paſſing the ſtreights of Gibraltar, viſited the weſtern coaſts of Spain and Africa. They revived a commercial intercourſe with Arabia and the continent of India, on the one hand, and with the eaſtern coaſt of Africa on the other; the cargoes which they purchaſed in Arabia, Ethiopia, and India, being landed at Elath, the ſafeſt harbour in the Red Sea towards the north: thence they were carried by land to Rhinocolura, the diſtance not being very conſiderable, and, being re-ſhipped in that port, were tranſported to Tyre, and diſtributed over the world.

The wealth which the Phenicians acquired by monopolizing the commerce of the Red Sea, incited their neighbours, the Jews, under the proſperous reigns of David and Solomon, to aim at being admitted to ſome ſhare of it. Solomon fitted out fleets, which, navigated by Phenician pilots and mariners, ſailed from the Red Sea to Tarſhiſh and Ophir, from whence they brought ſuch valuable cargoes as ſuddenly diffuſed wealth and ſplendour through the kingdom of Iſrael. But the inſtitutions of the Jews were by no means favourable to commerce, which was never carried to any great extent by them while they inhabited Judea.

The Carthaginians applied themſelves to commerce and navigation with ardour, ingenuity, and ſucceſs; but as the Phenicians had engroſſed the commerce of India, their adventures were chiefly made to the weſt and north. Following the courſe which the Phenicians had opened, they extended their voyages beyond the ſhores of the Mediterranean, viſiting not only all the coaſts of Spain, but thoſe of Gaul, and penetrating at laſt to Britain. They made voyages of diſcovery in different directions, and thus eſtabliſhed a commercial intercourſe with places which before were wholly unknown; but whatever knowledge of this kind they acquired, it was concealed from the inhabitants of other ſtates with the utmoſt care.

The Greeks, although their country was almoſt encompaſſed by the ſea, which formed many ſpacious bays and commodious harbours, and though it was ſurrounded by a number of fertile iſlands, were, notwithſtanding ſuch a favourable ſituation, a long time before they attained any degree of perfection in navigation. They ſcarcely carried on any commerce beyond the limits of the Mediterranean. Their chief intercourſe was with the colonies of their countrymen planted in the leſſer Aſia, in Italy, and in Sicily. They ſometimes viſited the ports of Egypt, of the ſouthern provinces of Gaul, and of Thrace, or paſſing through the Helleſpont, they traded with the countries ſituated around the Euxine ſea. The expedition of Alexander into the eaſt conſiderably enlarged the geographical knowledge of the Greeks. He had obſerved the reſources which commerce creates, in the exertions of the republic of Tyre, and therefore it became part of his plan to render the empire which he propoſed to eſtabliſh, the centre of commerce as well as the ſeat of dominion. With this view, he founded Alexandria near one of the mouths of the Nile, that, by the Mediterranean ſea, and the neighbourhood of the Arabian gulph, it might command the trade both of the eaſt and weſt. This ſituation was ſo judiciouſly choſen, that Alexandria ſoon became the chief commercial city in the world. Not only during the ſubſiſtence of the Grecian empire in Egypt and in the eaſt, but amidſt all the ſucceeding revolutions of thoſe countries, commerce, particularly that of the Eaſt Indies, continued to flow in the channel which the ſagacity and foreſight of Alexander had marked out for it, till the diſcovery of the navigation by the Cape of Good Hope opened a more expeditious and independent channel to all the maritime ſtates of Europe.

In the early periods of the Roman hiſtory, commerce appears to have been much neglected and undervalued; it ſeems to have been thought a degrading employ by this military people, and to have been left almoſt entirely in the hands of the natives of the countries they conquered. The extent, however, of the Roman power, which included the greateſt part of the known world, the vigilant inſpection of the Roman magiſtrates, and the ſpirit of the Roman government, no leſs intelligent than active, gave ſuch additional ſecurity to commerce, as animated it with new vigour; and, as ſoon as the Romans acquired a taſte for the productions of other countries, commerce, particularly the trade with India through Egypt, was puſhed with new vigour, and carried on to a greater extent. The pilots who ſailed from Egypt to India firſt ventured to quit ſight of the ſhore, and depending wholly on the trade winds, boldly ſailed from Ocelis at the mouth of the Arabian gulph, acroſs the ocean, to the coaſt of Malabar, returning with the eaſtern monſoon, and thus procuring the ſpices and other rich commodities of the continent and iſlands of the farther India, which were brought to the port of Muſiris by the Indians themſelves. The commerce thus carried on will appear conſiderable even in the preſent age, as the trade with India is ſaid to have drained the Roman empire every year of more than four hundred thouſand pounds, and that one hundred and twenty ſhips ſailed annually from the Arabian gulph to that country. The reign of Auguſtus was very favourable to commerce, as the peace which then prevailed over the civilized parts of the world, enabled the merchants to purſue it unmoleſted. Under Tiberius we find the Romans extending their protection to the north, and the town of Havern, the moſt ancient in Frieſland, founded. Under Nero, the capital of England is firſt mentioned as a conſiderable place. Tacitus, who lived for ſome time at London, ſays it was famous for its many merchants, and plenty of its merchandize. Rome, however, as the ſeat of wealth and luxury, continued to be the metropolis of the commercial world, until the fourth century, when Conſtantine removed the ſeat of empire to Conſtantinople, and made it the emporium of commerce. This city was undoubtedly well adapted for that honour; it was favoured by nature with a fine climate, and in a moſt advantageous ſituation for carrying on an extenſive correſpondence with every part of the world then known.

The invaſion by the northern nations in the fifth century, not merely arreſted the progreſs of commerce, but effectually diſſolved all commercial connections, and deprived the merchants of any market for their commodities. Europe became parcelled out into many ſmall and independent ſtates, differing from each other in language and cuſtoms; no intercourſe ſubſiſted between the members of theſe divided and hoſtile communities; their mode of life was ſimple, they had few wants to ſupply, and few ſuperfluities to diſpoſe of. Cities, in which alone an extenſive commerce can be carried on, were few, inconſiderable, and deſtitute of thoſe immunities which produce ſecurity or excite enterpriſe. It became diſagreeable and dangerous to viſit any foreign country, and thus the knowledge of remote regions was loſt; their ſituation, their commodities, and almoſt their names, were unknown. The preſervation of Conſtantinople from the general deſtruction, however, prevented commercial intercourſe with diſtant nations from ceaſing altogether. In that city the knowledge of ancient arts and diſcoveries was preſerved; a taſte for ſplendour and elegance ſubſiſted; the productions of foreign countries were in requeſt; and commerce continued to flouriſh there when it was almoſt extinct in every other part of Europe. The merchants of Conſtantinople did not confine their trade to the iſlands of the Archipelago, or to the adjacent coaſts of Aſia; they took a wider range, and following the courſe which the ancients had marked out, imported the commodities of the Eaſt Indies from Alexandria. When Egypt was torn from the Roman empire by the Arabians, the induſtry of the Greeks diſcovered a new channel, by which the productions of India might be conveyed to Conſtantinople. They were carried up the Indus, as far as that great river is navigable; thence they were tranſported by land to the banks of the river Oxus, and proceeded down its ſtream to the Caſpian ſea. There they entered the Volga, and ſailing up it, were carried by land to the Tanais, which conducted them into the Euxine ſea, where veſſels from Conſtantinople waited their arrival. This extraordinary and tedious mode of conveyance, Dr. Robertſon obſerves, is a proof not only of the violent paſſion which the inhabitants of Conſtantinople had conceived for the luxuries of the eaſt, and of the ardour and ingenuity with which they carried on commerce, but it demonſtrates, that during the ignorance which reigned in the reſt of Europe, a knowledge of remote countries was ſtill preſerved in the capital of the Greek empire. Robertſon's Hiſt. Amer. vol. i.

The devaſtations of the Huns in Italy induced many of the richeſt inhabitants of the country near the bottom of the Adriatic, to fly with their beſt effects into the numerous ſmall ſandy iſles lying amongſt the ſhallow waters near the ſhores of the continent; on which iſles, about ſeventy-two in number, they built ſuch habitations as their circumſtances would admit; and here by degrees aroſe the celebrated commercial city of Venice. Neceſſity firſt obliged them to devote themſelves to commerce, the earlieſt branch of which was naturally the fiſheries. Their next commercial object was the manufacture and exportation of ſalt. Thus by the application of its inhabitants, and the ſecurity of its ſituation, Venice gradually became the general magazine for the merchandize of the neighbouring continent, to which the many rivers that fall into the Adriatic ſea greatly contributed; and as the Venetians in time became the carriers of this merchandize into diſtant countries, they were enabled to bring back raw materials for various manufactures which greatly enlarged their commercial dealings.

In this manner, Venice firſt, and Genoa, Florence, and Piſa afterward, from inconſiderable places became populous and wealthy cities, and laid the foundation for the revival of commerce throughout the Mediterranean, which, in proceſs of time, was extended to the countries of Europe without the ſtreights of Gibraltar. The free cities of Italy, were, for ſeveral centuries, the only places in Europe, weſt of the Eaſtern or Greek empire, which had any conſiderable commerce, or any valuable manufactures for the ſupply of other nations. Their merchants frequented Aleppo, Tripoli, Alexandria, and other ports of Syria and Egypt, where they procured the produce of India; and viſiting the maritime towns of Spain, France, the Low Countries, and England, by diſtributing their commodities over Europe, communicated to its various nations ſome taſte for the valuable productions of the eaſt, as well as ſome ideas of manufactures and arts, which were then unknown beyond the precincts of Italy.

The firſt mention of the city of Antwerp, afterwards ſo famous for its trade, is in the year 517, when Theodoric expelled the Danes from it. Some towns in England, as Chicheſter and Abingdon, are ſaid to have been founded about this time, which ſhews that trade and manufactures were gaining ground in this country.

The unſettled ſtate of Europe, ariſing from the fierce and reſtleſs diſpoſition of the barbarous tribes who had taken poſſeſſion of the weſtern empire, cauſed for ſeveral centuries a great ſtagnation of commercial intercourſe. Venice however continued to improve its commerce, and London became "a mart town of many nations, which repaired thither by ſea and land." Some of the Italian cities began to aſſume a degree of independence, and ſeveral towns were founded in Germany and Flanders, which afterwards became of much commercial importance. The commerce of Europe revived a little under the government of Charlemagne, who, among other endeavours to promote it, is ſaid to have formed a project for uniting the two great rivers of the Rhine and the Danube, and thus forming a communication between the German ocean and the Black ſea, without ſailing up the Mediterranean. But his engineers had not ſufficient ſkill to overcome the difficulties they met with, and the undertaking was ſoon relinquiſhed. In a letter from this prince to Offa, king of Mercia, he grants leave for ſuch Engliſh as went in pilgrimage to Rome, to paſs through his dominions free; but ſuch as travelled for the purpoſes of trade were to pay the cuſtomary tolls; and promiſes that the merchants ſhould have legal patronage and redreſs of grievances. Theſe merchants were probably perſons who carried their whole ſtock with them, which of courſe could not be of any very great amount.

The eſtabliſhment of Chriſtianity in Germany produced a much more intimate and regular correſpondence between the north of Europe, and the earlier Chriſtianized countries of Italy, France, Spain, and Britain; ſo that their ſuperfluities and produce were mutually communicated to each other, while Germany received by degrees, from its intercourſe with thoſe countries, conſiderable improvements with reſpect to agriculture, mining, vine-dreſſing, manufactures, and the arts, more immediately conducive to the comforts of civilized life. It conſiderably increaſed the cities and towns, where cathedral churches and houſes for the biſhops and clergy were erected. Thus the propagation of Chriſtianity greatly favoured the advancement of commerce in the north of Europe; while Charlemagne by his conqueſt of Italy, and by rebuilding and reſtoring many of the decayed cities of that country, inſpired thoſe cities with the ſpirit of commerce, manufacture, and navigation, for which they became in after times ſo juſtly famous. This period may be conſidered as the firſt dawn of the revival of commerce in Europe; for although ſubſequent to this time the Saracens or Moors, and the Normans, by their ravages and conqueſts in various parts, greatly obſtructed and retarded its progreſs, yet in ſpite of all oppoſitiom, the free cities in both the extreme parts of Europe in conſequence of the increaſe of their wealth and population from the encouragement of commerce, gradually aroſe to very conſiderable importance.

In the tenth century, the commercial intercourſe which the Germans had previouſly cultivated with the neighbouring ſtates was much increaſed by the diſcovery of valuable ſilver mines at Goſlar in Saxony, which occaſioned other parts of Germany to be explored for mines with conſiderable ſucceſs. The woollen manufacture of Flanders began to acquire ſome degree of importance, being much encouraged by Baldwin, third earl of Flanders, who invited into the country all manner of handicraftſmen for making all ſorts of manufactures, to whom he granted great privileges. He alſo eſtabliſhed annual fairs, and fixed markets on ſtated days of the week at Bruges, Courtray, Torhout, Mont-Caſſel, and other places, where merchants could exchange their goods for others; for "by reaſon of the ſcarcity of money at that time, the Flemings dealt moſtly by permutation, or barter of one kind of merchandize for another: which we read was alſo the practice of almoſt all the Germans and Sarmatians."

The republic of Venice had now acquired ſo much wealth and ſtrength by the great extenſion of her commerce, as to have become a formidable political ſtate, and having annexed to their dominions many cities and towns on the eaſt coaſt of the Adriatic ſea, the doge of Venice aſſumed the title of duke of Dalmatia. They eſtabliſhed a regular commercial intercourſe with the Saracens of Egypt and Syria, "countries ever famous for the production of rice, ſugar, dates, ſenna, caſſia, flax, linen, balm, perfumes, galls, wrought ſilk, ſoap, &c. beſides the rich ſpices and precious ſtones of India, brought to thoſe two countries; with all this rich merchandize, the Venetians now traded all over the weſtern parts of Europe, to their immenſe profit." They obtained from the Greek emperors a freedom from all cuſtoms and taxes in their empire; and in the year 996 the emperor Otho III. likewiſe granted them various privileges, with a right to ſet up fairs in ſeveral parts of Germany, where they carried on a vaſt commerce.

The cruſades contributed materially to the extenſion of commerce during the 11th and 12th centuries. The Genoeſe, the Piſans, and the Venetians, furniſhed the tranſports neceſſary to carry the vaſt armies that embarked on theſe wild enterprizes: they alſo ſupplied them with proviſions and military ſtores. Beſides the immenſe ſums which they received on this account, they obtained commercial privileges and eſtabliſhments of great conſequence, in the ſettlements which the cruſaders made in Paleſtine, and in other provinces of Aſia. From theſe ſources they acquired great wealth, and a proportionate increaſe of power. By the expeditions into Aſia, the inhabitants of all the ſtates of Europe had an opportunity of obſerving the manners, the arts, and the accommodations of people more poliſhed than themſelves. The adventurers who returned from Aſia communicated to their countrymen the ideas which they had acquired, and the habits of life they had contracted by viſiting more refined nations. The Europeans began to be ſenſible of wants with which they were formerly unacquainted; and ſuch a taſte for the commodities and arts of other countries gradually ſpread among them, that they not only encouraged the reſort of foreigners to their harbours, but began to perceive the advantage and neceſſity of applying to commerce themſelves.

The great commercial progreſs of the city of Lubeck ſoon cauſed other towns to be founded in the neighbourhood of the Baltic; which, ſuffering much from the occaſional attacks of neighbouring powers, and the depredations of pirates, were induced to enter into an aſſociation for their mutual ſafety, and the protection of their navigation. Thus was gradually formed the famous Hanſeatic confederacy, which made ſo great a figure in the commercial hiſtory of ſeveral ſucceeding centuries, and of which Lubeck was from the firſt conſidered as the director or head. Werdenhagen fixes on the year 1169 for the firſt of this confederacy, which conſiſted of the twelve following towns on the Baltic ſhore: viz. Lubeck, Wiſmar, Roſtock, Straelſund, Grypeſwald, Anclam, Stetin, Colberg, Stolpe, Dantzick, Elbing, and Koningſberg; though probably not all of them at the firſt; as ſome of them do not appear to have been founded till a later period. Lambecius, librarian to the emperor Leopold, is of opinion, that the Hans-league did not properly commence till after the league between Lubeck and Hamburgh in 1241, at which time the towns comprehended in this aſſociation were in poſſeſſion of all the commerce of the ſouth ſhores of the Baltic, from Denmark to the bottom of the gulph of Finland, beſides an extenſive commerce to more diſtant parts. About this time the commerce of Norway began to acquire ſome degree of importance, and in a treaty between the monarch of that country and Henry III. of England, in 1217, it was agreed that their reſpective ſtates ſhould be free for merchants and others on both ſides.

At the beginning of the 13th century, the German merchants of the Steel-yard engroſſed all the foreign commerce which then exiſted in England, which at that time had very few merchants, and fewer ſhips of her own. About 1250, however, a ſociety of Engliſh merchants was formed, who are ſaid to have had privileges granted to them in the Netherlands, by John duke of Brabant; whither they had begun to reſort with Engliſh wool, lead, and tin, bringing in return fine woollen cloths, linen, and other articles. From this ſociety, the company ſtyled "Merchants of the ſtaple of England" took its riſe. In 1274, a treaty was concluded with the earl of Flanders for the ſettlement of ſome commercial diſputes which exiſted between the two countries.

France at this period poſſeſſed very little foreign commerce, but in the cities of Italy it had increaſed greatly. The republic of Genoa was in its meridian glory, being the greateſt maritime power then exiſting. Even Venice, great as it was now become, was eclipſed by Genoa, which, towards the concluſion of this century, had reduced the republic of Piſa, till then alſo powerful at ſea, to the loweſt ebb of fortune, never again to riſe to greatneſs, and ſoon to loſe her independence.

A new æra was now about to commence in commercial hiſtory. The diſcovery of that valuable, but now familiar inſtrument, the mariner's compaſs, Dr. Robertſon obſerves, may be ſaid to have opened to man the dominion of the ſea, and to have put him in full poſſeſſion of the earth, by enabling him to viſit every part of it. But the effects of this diſcovery were not ſo ſudden or extenſive as might be expected. The uſe of the compaſs enabled the Italians to perform the ſhort voyages to which they were accuſtomed, with greater ſecurity and expedition, but near half a century elapſed, before navigators ventured into any ſeas which they had not been accuſtomed to frequent. One of the firſt fruits of ſuch adventures, was the diſcovery of the Canary iſlands by the Spaniards.

Many of the princes of Europe were now becoming more ſenſible of the importance of commerce, which led them to enter into treaties for its regulation and defence. Edward I. in 1302 publiſhed his famous charter ſtyled Charta Mercatoria, by which "The merchants of Almaine, France, Spain, Portugal, Navarre, Lombardy, Florence, Provence, Catalonia, Aquitaine, Thoulouſe, Flanders, Brabant, and of all other foreign parts, who ſhall come to traffic in England, ſhall and may ſafely come with their merchandize into his cities, towns, and ports, and ſell the ſame, by wholeſale only, as well to natives as to foreigners." Some particular articles they were allowed to ſell by retail; and they were to export any goods they might want from England on paying the uſual cuſtoms, except wine, which could not be exported without a ſpecial licence. The countries here mentioned ſhew the parts to which the commerce of England was at that time chiefly confined; and a very good idea of its extent may be gained from the following account of the exports and imports, in the 28th year of Edward III. from a record in the Exchequer.

Exports.	£.	s.	d.
31,651½ ſacks of wool, at ſix pounds per ſack, and 3036 hundred weight and 65 fells, each hundred weight being 6 ſcore, at forty ſhillings per hundred weight, with the cuſtoms, &c. thereon, amounted to - - -	277,606	2	9
Leather, with its cuſtom - - - - - -	96	2	6
4774½ coarſe cloths, at 40 ſhillings each, and 8061½ pieces of worſted, at 16*s.* 8*d.* per piece - - - - - - -	16,266	18	4
Cuſtoms thereon - - - - - - - - - -	215	13	7
Total Exports, with the duties thereon	294,184	17	2

Imports.			
1831 fine cloths, at 6*l.* per cloth, which, with the cuſtoms, comes to -	11,083	12	0
397¾ hundred weight of wax, at 40 ſhillings per hundred weight, which, with the cuſtoms, comes to - - - - -	815	7	5
1829½ tons of wine, at 40 ſhillings per ton, which, with the cuſtoms, comes to - - - - - - - - - - - - -	3,841	17	0
Linen cloth, mercery, grocery, and all other wares whatever - - - - -	22,943	6	10
On which the cuſtom was - - - - - -	285	18	3
Total Imports, with the duties thereon	38,970	3	6

Thus, as ſir William Temple obſerves, "when England had but a very ſmall foreign commerce, we were rich in proportion to our neighbours, by ſelling ſo much more than we bought." It is not very probable, however, that the exceſs of the exports was generally ſo great as is here ſtated.

The materials of commerce were now increaſing by the improvement of manufactures in various parts of Europe; while the diſcoveries of the Portugueſe on the coaſt of Africa, and in the adjacent ſeas, excited a more enterpriſing ſpirit of mercantile adventure, and at length, in 1487, led to the diſcovery of the Cape of Good Hope, which they doubled about ten years after, and thus accompliſhed the firſt regular voyage to the Eaſt Indies. About the ſame time alſo was accompliſhed the great diſcovery of the weſtern continent. Theſe events, which filled the world with aſtoniſhment, and gave riſe to an infinity of new ſpeculations, have ſince ſupplied it with a prodigious increaſe of wealth, and with many new and excellent materials for the immenſe additional commerce which has thus accrued to all the ſtates of Europe.

The whole of the vaſt regions diſcovered in the Eaſt and Weſt, was by the papal authority divided between the Spaniards and Portugueſe. The former firſt made herſelf miſtreſs of the iſlands, and next of the principal part of the continent of America; in conſequence of which the cities of Seville and Cadiz became the ſtore-houſes for the riches of the newly-diſcovered weſtern world. Portugal purſued her commerce and rapid conqueſts in the Eaſt Indies, ſo that

Liſbon ſoon became (what the now declining city of Venice had been for many centuries paſt) the great magazine for all the rich productions of the Eaſt. They had alſo diſcovered Braſil in South America, which ſoon became an almoſt inexhauſtible fund of wealth to Portugal, which may be ſaid to have been then at the height of its commercial greatneſs.

In the courſe of the 16th century many circumſtances occurred which contributed greatly to the extenſion of commerce. The Engliſh in the purſuit of a north-weſt paſſage to India had diſcovered the whole coaſt of North America, where, after ſome years, they began to attempt ſettlements. They engaged in the Newfoundland fiſhery, and alſo in the whale fiſhery at Spitſbergen or Greenland. The continual jealouſies and diſputes between the Engliſh merchants and the German Hanſeatic merchants of the Steel-yard in London, were at length terminated by the abolition of the peculiar privileges of the latter. The diſcovery of a paſſage to Ruſſia round the north Cape of Lapland, opened a field for other new diſcoveries, and new branches of commerce; in conſequence of which a company for trading to Ruſſia was immediately formed and incorporated. The commerce with Turkey was encouraged by the incorporation of a company; and the intercourſe with Guinea and other places on the coaſt of Africa, was alſo thought of ſufficient importance to have a company eſtabliſhed for carrying it on.

While the importance of the Italian cities was declining, and the commerce of the towns on the Baltic experiencing ſome diminution, the cities of Hamburgh and Antwerp had riſen into conſiderable importance. The latter in particular, from the convenience of its ſituation, might for ſome time be conſidered as the centre of the commerce of Europe, as well for the merchandize of both the Indies, as for the naval ſtores and other bulky commodities of the northern ſtates. It was however ſoon to find a rival among its induſtrious neighbours in the United Provinces, who, from the time of their independence, applied themſelves to manufactures and commerce with the utmoſt aſſiduity. France was at this time beginning to encourage the cultivation of the vine, and the improvement of her broad ſilk manufacture; while Spain, by expelling the proteſtants from the Netherlands, ſupplied England, Holland, and the Hanſe-towns with great numbers of wealthy and induſtrious manufacturers and artificers, as well as with an acceſſion of many ingenious and beneficial new manufactures.

The 17th century was the period in which the principles were adopted, and moſt of the eſtabliſhments formed, which have contributed to advance the commerce of Europe to its preſent aſtoniſhing height. The intereſts of nations became better underſtood than in any former age; the utility of commerce had become evident to every one, from the wealth and power it had conferred on the ſtates which had encouraged it; and commercial treaties became frequent between the different nations. Navigation was improved; new ſettlements were formed, and many of thoſe before made were riſing into importance; manufactures were advancing in many parts of Europe; ſhipping was increaſing, and the intercourſe between diſtant places, from the accumulation of knowledge and experience, becoming more expeditious and ſecure.

The lucrative commerce of the Eaſt became one of the leading objects of mercantile purſuit. An Engliſh Eaſt India company was formed in 1600; and the Dutch companies, which were united in 1602, became one of the moſt celebrated commercial eſtabliſhments ever formed. The French viſited the Eaſt Indies in 1601, but did not eſtabliſh a regular company for carrying on the trade till 1664. The Danes eſtabliſhed an Eaſt India company in 1617, and in 1627 the king of Sweden iſſued letters patent for forming an Eaſt India company, but it was not carried into execution till ſome years after. The Spaniards and Portugueſe, however, at this period, poſſeſſed by far the greateſt ſhare of the commerce of India, which had now become very conſiderable. The following account publiſhed by Mr. Munn, in 1621, of the quantity of Indian merchandize conſumed annually in Europe, gives a very good idea of the proportion of the different articles of this branch of commerce: the prices affixed are the prime coſt in India, including all charges till actually ſhipped for Europe.

	s.	*d.*	
6,000,000 lb. pepper, at	0	2½	per lb.
450,000 lb. cloves, at	0	9	per lb.
150,000 lb. mace, at	0	8	per lb.
400,000 lb. nutmegs, at	0	4	per lb.
350,000 lb. indigo, at	1	2	per lb.
1,000,000 lb. raw ſilk, at.	8	0	per lb.

This ſtatement was probably meant to include only the principal articles; at leaſt it is certain that about 1631 ſeveral other kinds of merchandize were uſually imported from India, as taffaties, painted callicoes, drugs of various ſorts, and China ware. Tea, the great object of commercial intercourſe with China, was either not yet an object of commerce, or was imported in ſuch ſmall quantities, that in England at leaſt, in 1660, it was not thought of ſufficient conſequence to be ſubjected to a duty.

Dr. Davenant, who publiſhed his "Diſcourſes on Trade" in 1698, was of opinion, that from about the year 1656 to 1688, England had every year gradually increaſed in riches; and that about the laſt mentioned year, the increaſe or addition to the wealth, and general ſtock of the nation, ariſing from foreign trade and home manufactures, was at leaſt two millions per annum. In this eſtimate the different branches of trade are ſtated as follows:

The plantation trade may bring in -	£ 600,000
The Eaſt India trade may bring in -	500,000
The European, African, and Levant trade, by our own product may bring in - - -	600,000
Ditto, by re-exports of plantation goods - - -	120,000
Ditto, by re-exports of Eaſt India goods - - -	180,000
Total	2,000,000

This account is probably ſomewhat beyond the truth, with reſpect to the period to which it refers; but that there had been a conſiderable influx of wealth, is ſhewn by the obſervations of the ſame author, that from the year 1600 to 1688, the general rental of England was nearly trebled, and the purchaſe of land half doubled; that the ſtock of the kingdom was multiplied above five fold, and the money in circulation above four fold. This rapid advance in wealth, can be aſcribed to no other cauſe than the improvement of commerce, which was now becoming of the utmoſt importance to all the European ſtates, particularly to ſuch as were deſirous of maintaining any degree of naval power.

The increaſe of wealth ariſing from the extenſion of commerce, gave riſe to the eſtabliſhment of banks, by which its operations have of late years been ſo much facilitated. The commercial cities of Venice and Genoa had long experienced the utility of ſuch inſtitutions, which were now adopted in other ſtates. The banks of Amſterdam, of

Hamburgh, and of Rotterdam were eſtabliſhed; and in 1694, the bank of England, and the bank of Scotland. The buſineſs of private bankers likewiſe took its riſe, and had become conſiderable, when it received a ſevere check from the unjuſtifiable conduct of Charles II. in ſeizing the money which the bankers had advanced on credit of the taxes. This branch of mercantile intercourſe has however been ſince carried to an extent which in former times would have been deemed wholly incredible.

Thus, with its principles generally underſtood; with moſt of the eſtabliſhments formed which are neceſſary to facilitate its operations; with laws and treaties in force for its encouragement and protection; markets eſtabliſhed for the purchaſe or ſale of commodities in almoſt every part of the globe; navigation brought to a high degree of perfection, vaſt improvements in arts and manufactures; and a great increaſe of artificial wants from the progreſs of luxury and refinement; the commerce of the world, and particularly of Europe, has, during the 18th century, expanded in an aſtoniſhing degree, and become intimately connected with the political exiſtence of almoſt every ſtate.

COMMERCE *of Great Britain.* The moſt authentic materials from which an idea can be formed of the progreſs and extent of the commerce of Great Britain, are the accounts kept in the office of the inſpector-general of exports and imports, at the cuſtom-houſe of London. Theſe accounts do not ſhew the current value of the commodities exported or imported, but are formed from their quantities, according to certain rates of value affixed to the ſeveral articles of foreign trade in 1696, by which they have been rated ever ſince. It is evident, therefore, that, as the price of all kinds of merchandize is ſubject to great fluctuations, and in general has much increaſed in this country within the laſt hundred years, theſe accounts are far from ſhewing the actual values in the later years; they are, however, from this very circumſtance of being uniformly made up at the ſame rates, the better adapted to a comparative view, and ſhew a progreſſive increaſe which has arrived to an amount never before known in the commerce of any nation. According to theſe eſtimates the total amount of the exports and imports of Great Britain have been as follows:

Years.	Imports.	Exports.
1700	£5,970,175	£7,302,716
1701	5,869,606	7,621,053
1702	4,159,304	5,235,874
1703	4,526,596	6,644,103
1704	5,383,200	6,552,019
1705	4,031,649	5,501,677
1706	4,113,933	6,512,086
1707	4,274,055	6,767,178
1708	4,698,663	6,969,089
1709	4,510,593	6,627,045
1710	4,011,341	6,690,828
1711	4,685,785	6,447,170
1712	4,454,682	7,468,857

At the concluſion of the war, by the peace of Utrecht, a commercial treaty with France was likewiſe negociated: but when the particulars of it came to be diſcuſſed, two of the articles, by which the produce and manufactures of France were to be admitted into this country on the ſame terms as thoſe of the moſt favoured nation, excited ſuch general diſapprobation, that the bill for carrying it into effect was rejected by the houſe of commons. The ſtrongeſt objection to the principle of the treaty, was that it might ruin the trade then carried on with Portugal, which was conſidered as the moſt valuable branch of our European commerce.

It is evident, that from the year 1705, notwithſtanding the diſadvantages it always labours under in time of war, commerce had been gradually increaſing; but when peace enabled it to return to its uſual channels, and reſtored ſome branches which had been conſiderably interrupted, its general advancement became more obvious, and although from the mode then uſually adopted, of judging of the profits of commerce merely by the exceſs of the value of the exports, the balance appeared leſs than it had been in former years, the wealth which flowed into the country from foreign trade, being no longer abſorbed in public wars, ſoon enabled the government to make a permanent reduction in the legal rate of intereſt. The war with Spain in 1718, did not cauſe much interruption of commercial intercourſe, except in the direct trade with that country.

Years.	Imports.	Exports.
1713	£5,811,077	£7,352,655
1714	5,929,227	8,361,638
1715	5,640,943	7,379,409
1716	5,800,258	7,614,085
1717	6,346,768	9,147,700
1718	6,669,390	8,255,302
1719	5,367,499	7,709,528
1720	6,090,083	7,936,728
1721	5,768,510	8,681,200

At this period the judicious principle of promoting the exportation of Britiſh manufactures, which had hitherto been applied only to woollen goods, was extended to Britiſh manufactures and produce in general; which were allowed to be exported duty free, except a few articles chiefly materials for manufactures, the exportation of which it would not have been proper to encourage; while drugs and other materials uſed for dyeing, were, upon being firſt duly entered, to be imported duty free, but upon re-exportation were to pay ſpecific duties. For this highly beneficial regulation, ſo ſimple in its principle, and ſo comprehenſive in its extent, the country was indebted to the enlightened wiſdom of Mr. Walpole: the experiment excited much doubt and ſolicitude as to its ſucceſs, but it ſoon appeared that the loſs of revenue in the duties thus given up, was a mere trifle in compariſon with the ſtimulus it gave to manufactures and the conſequent extenſion of commerce.

Years.	Imports.	Exports.
1722	£6,378,098	£9,650,789
1723	6,505,676	9,489,811
1724	7,394,405	9,143,356
1725	7,094,708	11,352,480
1726	6,677,865	9,406,731
1727	6,798,908	9,553,043
1728	7,569,299	11,631,383
1729	7,540,620	11,475,771
1730	7,780,019	11,974,135
1731	6,991,500	11,167,380
1732	7,087,914	11,786,658
1733	8,016,814	11,777,306
1734	7,095,861	11,000,645
1735	8,160,184	13,544,144
1736	7,307,966	11,616,356
1737	7,073,638	11,842,320
1738	7,438,960	12,289,495

The above period was almoſt wholly a time of peace, during which the commerce of Great Britain was gradually advancing, both from the improvement of ſeveral of the exiſting branches, and the acquiſition of new ones. The South-ſea company undertook the Greenland whale fiſhery, which had been entirely relinquiſhed by this country for ſome years paſt; and encouragement was given to fiſheries on the coaſt of America. Attempts were made to obtain a ſhare of the fur trade of north America, which was almoſt entirely in the hands of the French. The Oſtend Eaſt India company, which had been found prejudicial to the Engliſh trade in thoſe parts, was ſuſpended; while our trade with China increaſed conſiderably, particularly in the article of tea. The trade of the Levant company was very flouriſhing; as was likewiſe that of the Hudſon's bay company, though the latter was but of ſmall extent. The produce of ſeveral valuable commodities was at the ſame time augmenting, from an increaſed cultivation of rice in the American colonies, and of coffee in the Weſt India iſlands, while great quantities of corn were annually exported from Great Britain to France, Portugal, Spain, and Italy.

The war which began in 1739, was occaſioned chiefly by diſputes reſpecting our commerce in the Weſt Indies, which had been much interrupted by the Spaniards. It cauſed, at firſt, ſome decline of foreign trade, which however ſoon regained the extent to which it had been carried during the preceding peace.

Years.	Imports.	Exports.
1739	£7,829,373	£9.495,366
1740	6,703,778	8,869,939
1741	7,936,084	11,469,872
1742	6,866,864	11,584,427
1743	7,802,353	14,623,653
1744	6,362,971	11,429,628
1745	7,847,123	10,497,329
1746	6,205,687	11,360,792
1747	7,116,757	11,442,049
1748	8,136,408	12,351,433

At this time, a much greater proportion of the exports conſiſted of unmanufactured produce than it has ſince; as it appears there had been exported from England in five years, from 1744 to 1748, no leſs than 3,768,444 quarters of corn, which at medium prices was worth 8,007,948 *l*.

That a conſiderable increaſe of commerce had taken place, is evident from the quantity of ſhipping employed. The total tonnage of veſſels that cleared outwards on an average of three years preceding the war, had been 503,568 tons; the average of the three years, ending with 1751, was 661,184 tons. The encouragement of the fiſheries, and the regulation of the Guinea or African trade, which had been in the hands of an excluſive company, but was now in a great meaſure laid open; cauſed ſome extenſion of foreign trade, although the Levant, or Turkey trade, which had been conſidered as one of the moſt valuable branches, was beginning to decline rapidly, from the French improving the natural advantages they poſſeſs for a trade with thoſe parts.

Years.	Imports.	Exports.
1749	£7,917,804	£14,099,366
1750	7,772,039	15,132,004
1751	7,943,436	13,967,811
1752	7,889,369	13,221,116
1753	8,625,029	14,264,614
1754	8,093,472	13,396,853
1755	8,772,865	12,182,255
1756	7,961,603	12,517,640
1757	9,253,327	13,438,285
1758	8,415,025	15,034,994
1759	8,922,976	14,696,892
1760	9.832,802	15,579,073
1761	9 543,901	16,365.953
1762	8,870,234	14,134,093

It is evident that commerce had not been very materially affected by the war. The years 1755 and 1756 marked the loweſt point of its depreſſion; whence it gradually roſe, till it had gained a ſuperiority over the unexampled traffic of 1750, a year of eſtabliſhed peace and ſecurity.

By the peace of 1763, although many iſlands which had been taken in the Weſt Indies were reſtored, Great Britain retained a number of newly acquired iſlands, perhaps more than could be immediately brought into cultivation with advantage. The arrangements reſpecting Aſia were very favourable to the Eaſt India company; and in Africa an excluſive trade was ſecured in the article of gum Senegal, a material indiſpenſably neceſſary to the perfection of many of our manufactures. The immediate conſequence, however, of the acquiſition of additional territories, was, that a wide field was opened for ſpeculation and commercial enterpriſe, which cauſed much productive capital to be withdrawn from the trade and manufactures of Great Britain; yet our merchants were not only able to maintain their own credit, but alſo to aſſiſt their correſpondents during the commercial embarraſſments in Holland and other parts of the continent.

In 1765, the principles and meaſures were adopted which ſoon involved the country in diſputes with its American colonies. Impolitic reſtrictions were laid on a beneficial intercourſe which had long ſubſiſted between the Britiſh colonies and the Spaniſh Weſt India ſettlements; which being ſoon followed by other cauſes of diſcontent, drove the Americans into public reſolutions to make no further importations from Great Britain, but ſuch as were unavoidably neceſſary, and to encourage, to the utmoſt of their power, every kind of manufacture that was practicable among themſelves. This ſtep ſoon produced ſerious effects in Great Britain; the merchants connected with America found themſelves unable to fulfil their engagements by the ſtoppage of large ſums due to them from that country; the whole ſyſtem of their buſineſs was deranged, and general diſtreſs ſpread through the circle of their connections; the manufacturers ſuffered by the want of regular payments from the merchants, while their materials, and made up goods, to an alarming amount, were becoming a dead ſtock upon their hands; in conſequence of which, great numbers of workmen were thrown out of employ. Petitions were preſented to parliament from all the trading and manufacturing towns, which probably had ſome effect in procuring a temporary adjuſtment of the diſpute.

The non-importation agreement in America, was renewed in 1769 and 1770; yet the commerce of Great Britain, notwithſtanding theſe interruptions of an important branch of it, continued to increaſe; and previous to the war which followed, had attained to a greater extent than in any former years.

Years.	Imports.	Exports.
1763	£11,665,036	£16,160,181
1764	10,364,307	16,512,403
1765	10,889,742	14,550,507
1766	11,475,775	14,024,964
1767	12,073,956	13,844,511
1768	11,878,661	15,117,982
1769	11,908,560	13,438,236

1770

Years.	Imports.	Exports.
1770	12,216,937	14,266,653
1771	12,821,995	17,161,146
1772	14,508,715	18,732,379
1773	12,522,643	16,654,052
1774	14,548,902	17,607,447

The prohibition of all trade and intercourſe with the American colonies excited ſerious alarms, not only on account of the loſs of a valuable branch of trade, but from the ſuppoſed encouragement which the acquiſition of it would give to the trade of thoſe powers who aſſiſted the colonies. Theſe apprehenſions, however, in a few years appeared to be in a great meaſure groundleſs, many Britiſh manufactures found their way to America, though not imported directly from hence; and Mr. Chalmers obſerves, that "there was an evident tendency in our traffic to riſe in 1779, till the Spaniſh war impoſed an additional burthen. There was a ſimilar tendency in 1780, till the Dutch war added, in 1781, no inconſiderable weight. And the year 1781, accordingly, marks the loweſt degree of depreſſion, both of our navigation and our commerce, during the war of our colonies. But with the ſame vigorous ſpirit, they both equally roſe, in 1782, as they had riſen in former wars, to a ſuperiority over our navigation and commerce, during the year wherein hoſtilities with France began."

Years.	Imports.	Exports.
1775	£ 14,816,955	£ 16,946,523
1776	12,449,189	15,685,107
1777	12,643,834	14,152,243
1778	10,975,533	12,375,712
1779	11,435,263	13,597,771
1780	11,714,967	13,689,073
1781	12,723,613	11,470,388
1782	10,341,628	13,224,637

The opportunity of renewing the commercial connections between this country and America, from the concluſion of peace, was eagerly embraced; but ſubſequent experience proved, that a greater degree of caution had now become neceſſary to render it a beneficial trade. The arrangements relative to the commerce of Ireland, had a very beneficial effect in that country, which had hitherto been excluded from almoſt every ſpecies of commerce, and reſtrained from ſending the produce of her own ſoil to foreign markets. The convention with Spain ſettled more accurately the limits within which Britiſh ſubjects were allowed to cut logwood on the Muſquito coaſt, and conſequently gave greater certainty and ſecurity to the trade with thoſe parts. The commercial treaty with France, by diſcontinuing many of the prohibitions and prohibitory duties which had exiſted for almoſt a century between the two nations, opened a wide field for ſpeculation and adventure. The conſolidation of the cuſtoms by the abolition of all the confuſed and complex duties which then exiſted, and the ſubſtitution of a ſingle duty on each article in their ſtead, was a meaſure of great convenience to all perſons engaged in mercantile tranſactions. Under all theſe circumſtances, ſupported by the improvements which had taken place in ſeveral of the principal manufactures, the foreign trade of Great Britain increaſed greatly during the peace, and in the year 1792, had attained to an unparallelled height, both in point of value, and with reſpect to quantity of ſhipping employed in it.

Years.	Imports.	Exports.
1783	£ 13,122,235	£ 15,450,778
1784	15,272,802	14,961,074
1785	16,279,490	16,770,239
1786	15,786,072	16,300,730
1787	17,804,024	16,870,114
1788	18,027,170	17,472,408
1789	17,821,102	19,340,548
1790	19,130,886	20,120,121
1791	19,669,782	22,731,995
1792	19,659,358	24,905,200

The total number of veſſels which belonged to the ſeveral ports of the Britiſh empire on the 30th September 1792, was 16,079; the amount of their tonnage 1,540,145 tons; and the number of men and boys uſually employed in navigating them 118,286. The number of veſſels that entered inwards at the ſeveral ports of Great Britain (including their repeated voyages) was as follows:

	Ships.	Tons.
Britiſh - - -	12,030	1,587,645
Foreign - - -	2,477	304,074
Total	14,507	1,891,719

At this period, the commerce of Great Britain was generally admitted to be in a very flouriſhing ſtate. The application and improvement of machinery in almoſt every branch of manufacture, had reduced the charges of workmanſhip ſo far, as to enable our manufacturers to ſupply foreign markets on better terms than any other country could offer; while the increaſe of capital, ariſing from the accumulation of the profits of ſucceſsful commerce during a period of peace, gave our merchants the means of allowing longer credit than could be obtained elſewhere. The high price of the public funds, led many perſons to employ their money in diſcounting private ſecurities, which greatly facilitated the extenſion of commercial credit, but probably tempted ſome to trade much beyond the amount which their capital juſtified, or to ſpeculate largely without any real property of their own; ſo that when the apprehenſion of war produced a greater degree of caution, and began to affect particular branches of trade, many were involved in embarraſſments; and on the commencement of the war in 1793, commercial concerns, in general, experienced a ſerious ſhock. The aſſiſtance afforded by government to ſuch houſes as appeared to be really ſolvent, by lending them exchequer bills for a certain time, operated very ſucceſsfully, and averted the conſequences that were apprehended; credit revived, and as the war in its progreſs almoſt annihilated the foreign trade of ſome of the powers engaged in it, the commerce of Great Britain received a conſiderable augmentation; and, protected by its naval ſuperiority, continued to increaſe, notwithſtanding all the meaſures which political animoſity could deviſe to obſtruct or deſtroy it.

Years.	Imports.	Exports.
1793	£ 19,256,717	£ 20,390,180
1794	22,288,894	26,748,967
1795	22,736,889	27,312,338
1796	23,187,319	30,424,184
1797	21,013,956	28,917,010
1798	27,857,889	33,591,777
1799	26,837,432	35,991,329

Years.	Imports.	Exports.
1800	30,570,605	43,152,019
1801	32,795.557	42,301,701

The increaſe during the above period, though really very great, was not however equal to what it would appear from the above accounts to have been. This irregularity in the comparative view which the account of imports and exports generally furniſhes with ſufficient accuracy, of the commerce of Great Britain, ariſes from the article of coffee, the import of which was formerly little more than ſufficient to ſupply its ſmall conſumption in this country. But the interruption of the trade of France, the conqueſt of their Weſt India iſlands, and the greatly increaſed cultivation of coffee in Jamaica, cauſed nearly the whole ſupply of the continent with this commodity to depend during the war on Great Britain. In the inſpector-general's book of rates, coffee is valued on importation at 7 *l.*, and on exportation, at no leſs than 14 *l.* 10 *s.* per cwt.; while, during the above period, the real average value was about 5 *l.* per cwt. when imported, and 5 *l.* 10 *s.* when exported. The official account, therefore, from 1794, when coffee ſuddenly became a very conſiderable article of exportation, requires ſome correction; and if the over-eſtimated value of this article is deducted, the exports of the year 1800 will appear to have been 38,120,120 *l.*, and of 1801, 37,786,856 *l.*

The ſhort interval of peace in 1802, produced an immediate extenſion of foreign trade; and Mr. Addington thought himſelf juſtified "in pronouncing the commerce of the country to be in a ſtate of unrivalled and unexampled proſperity." The value of Britiſh manufactures exported, conſiderably exceeded the preceding year, and the total amount of the exports, according to the official values, was 46,120,962 *l.* But in this and the ſucceeding years, it will be proper to adopt the correction juſt mentioned, which will give the amount of the imports and exports as follows:

Years.	Imports.	Exports.
1802	£ 31,442,318	£ 41,411,966
1803	27,992,464	31,578,495
1804	29,201,490	34,451,367
1805	30,344,628	34,954,845
1806	31,094,089	36,528,132

The account of imports for the laſt year is not quite correct; the imports from the Eaſt Indies for that year being incomplete.

Almoſt every article being greatly under-valued in theſe accounts (except in one or two inſtances) the total muſt give a very inadequate idea of the real extent of the commerce of Great Britain. Some idea may be formed of the under-valuation of the imports by thoſe of the Eaſt India company, taking the account of their ſales as the importation; the medium value of which, on an average of three years, was 6,100,000 *l.*; whereas, the medium value by the accounts of the inſpector-general, for the ſame three years, was 4,572,000 *l.* Of the actual value of Britiſh produce and manufactures exported, which uſually conſtitutes about two-thirds of the total export, we have more correct information. By an act paſſed in 1798, and revived in 1802, called the convoy act, the exporters were required to declare the real value of Britiſh manufactures exported, in order to aſcertain the amount of duty chargeable thereon; and from theſe declarations, the actual value of Britiſh produce and manufactures exported has been aſcertained as follows:

In 1803	£ 40,100,870
1804	40,349,642
1805	41,068,942
1806	43,242,176

The extent of ſhipping employed in commercial intercourſe at this period, will be ſeen in the following account of the number of veſſels which belonged to the ſeveral ports of the Britiſh empire, on the 30th September 1805.

	Ships.	Tons.	Men & Boys.
England - - -	14,790	1,799,210	117,668
Jerſey & Guernſey	185	16,528	2,011
Iſle of Man - -	404	9,650	2,336
Scotland - - -	2,581	210,295	15,160
Ireland - - - -	1,067	56,806	5,070
The Plantations -	3,024	190,953	15,407
	22,051	2,283.442	157,712

The commerce of Great Britain with *Ireland*, has increaſed with the improvement of that country, particularly ſince the year 1780, when a more liberal ſyſtem of policy was adopted with reſpect to the foreign trade of Ireland. The imports from thence conſiſt chiefly of butter, beef, pork, bacon, lard, tallow, cattle, hides, feathers, ſtarch, rape-ſeed, linens, linen-yarn, woollen-yarn, pearl-aſhes, copper-ore, and a few other articles of leſs importance. The exports are coals, ironmongery and hardware, hoops for barrels, beer, cyder, dried cod, herrings, chiefly from Scotland, earthenware, bottles and window-glaſs, refined ſugar, hops, lead, tin-plates, ſail-cloth, cabinet-ware, wearing apparel, apothecaries-ware, books and ſtationary, painters' colours, hats, haberdaſhery, woollen, cotton, and ſilk manufactures of all kinds; with rum, brandy, geneva, wines, groceries, drugs, dye-ſtuffs, flax and hemp, raw and thrown ſilks, and other foreign produce.

Years.	Imports.	Exports.
1798	£ 2,735,686	£ 2,974.363
1799	2,770,731	4,086,986
1800	2,312,824	3,741,499

Conſiderable endeavours have been made to improve the manufactures of Ireland, but with little ſucceſs, except in the linen manufacture, which probably proceeds from the want of ſufficient capital, and from the facility with which Britiſh manufactures can be procured at a very ſmall additional expence; the latter will, therefore, for a long time, continue to conſtitute a large proportion of the imports of Ireland.

Value of Britiſh manufactures exported from Great Britain to Ireland.

In 1791	£ 1,470,972	In 1796	£ 1,781,789
1792	1,511,844	1797	1,310,996
1793	1,055,276	1798	1,657,954
1794	1,281,316	1799	2,405,999
1795	1,612,270	1800	1,787,966

The trade between Great Britain and *Ruſſia* has been conſidered highly beneficial to both countries; to Ruſſia in point of profit, and to Great Britain, as ſupplying articles eſſential to the ſupport of its navy. The capital employed muſt be much greater than formerly, from the increaſed value of the principal articles; and the balance of trade, which is conſiderably in favour of Ruſſia, is paid by means of the commercial tranſactions between Great Britain and other countries. The articles imported are iron, hemp, flax, tallow, pot-aſhes, deals, and lath-wood, coarſe linens, hog's briſtles, &c. The exports are principally broad-cloths and woollen ſtuffs, refined ſugar, cotton, lead, tin, iron and ſteel ware, earthen ware and glaſs, coals, alum, ſalt, horſes, London porter, with articles of leſs importance.

Years.	Imports.	Exports.
1800	£ 2,382,098	£ 1,025,335
1801	2,246,877	919,843
1802	2,182,430	1,376,399

The total number of veſſels that entered inwards from Ruſſia, and that cleared out for that country from Great Britain in three years, ending with 1806, was as follows:

	Inwards.		Outwards.	
Years.	Britiſh.	Foreign.	Britiſh.	Foreign.
1804	830	29	558	53
1805	961	14	927	52
1806	1106	21	677	32

The trade to *Denmark* and *Norway*, though of ancient date, is not of very great extent; the imports conſiſt chiefly of timber and corn; and the exports, of Weſt India produce and other foreign merchandize; the quantity of Britiſh manufactured goods which thoſe countries take being of ſmall amount.

Years.	Imports.	Exports.
1800	£ 241,563	£ 540,698
1801	208,794	416,475
1802	155,672	537,517

The total number of veſſels which entered inwards from Denmark and Norway, in the year 1806, was 1607, of which 529 were Britiſh ſhips: the total number which cleared outwards was 1690, of which 790 were Britiſh.

The trade with *Sweden*, which is carried on chiefly in ſhips of that country, has not varied materially in its extent during the laſt twenty years. The imports conſiſt chiefly of iron of a ſuperior quality, pitch, tar, deal boards, and ſail-cloth. The exports are principally colonial produce.

Years.	Imports.	Exports.
1800	£ 309,280	£ 78,840
1801	295,645	111,254
1802	327,350	108,296
1803	288,651	98,045

The total number of veſſels which entered inwards from Sweden, in the year 1806, was 353, of which 187 were Britiſh ſhips: the total number which cleared outwards was 362, of which 142 were Britiſh.

The imports from *Pruſſia*, conſiſt of all kinds of grain, hemp, flax, madder, lintſeed, gooſe-quills, briſtles, pearl-aſhes, mill-ſtones, and timber of various deſcriptions. The exports are chiefly alum, copperas, coals, beer, ſalt, wrought braſs and iron, lead, tin plates, earthen-ware, glaſs, woollen and cotton goods, ſome cotton yarn, India goods, raw and refined ſugar, drugs, dye-ſtuffs, pepper and other ſpices, coffee, rum, tobacco, &c.

Years.	Imports.	Exports.
1800	£ 1,340,904	£ 794,452
1801	1,387,149	660,739
1802	1,057,602	1,071,896
1803	831,225	1,916,502

The total number of veſſels which entered inwards from Pruſſia in the year 1805 was 1946, of which 837 were Britiſh ſhips: the total number which cleared outwards was 1627, of which only 482 were Britiſh. In 1806 the total numbers were much leſs, in conſequence of Pruſſia being involved in the war.

The trade with *Germany* had not experienced any conſiderable variation with reſpect to its extent, from the commencement of the laſt century, till on the extenſion of the war with France in 1794, it ſuddenly became the channel through which the principal part of the continent received the goods they had before obtained direct from Great Britain. The following account of exports to Germany ſhews the rapid increaſe of trade with that country during the war.

Years.	Britiſh Manufactures.	Foreign Merchandize.
1793	£ 718,474	£ 1,764,221
1794	1,634,530	4,308,695
1795	1,760,133	6,311,876
1796	1,591,810	6,582,179
1797	1,964,967	6,419,587
1798	2,042,774	8,646,691
1799	2,032,567	6,640,729
1800	4,364,120	8,300,470
1801	4,928,617	6,186,687

The total number of veſſels which entered inwards in the ſeveral ports of Great Britain from Germany (including Hamburgh) and which cleared outwards for that country, was as follows:

	Inwards.		Outwards.	
Years.	Britiſh.	Foreign.	Britiſh.	Foreign.
1793	217	54	292	77
1794	258	108	443	152
1795	259	222	257	406
1796	347	342	333	415
1797	237	257	314	371
1798	408	113	647	187
1799	409	126	426	181
1800	435	459	574	458

The total number of veſſels which entered inwards from Germany (including Hamburgh) in the year 1806 was 604; the total number which cleared outwards for that country 956.

The imports from *Holland* are butter and cheeſe in large quantities, geneva, juniper berries, flax, hemp, oak bark, rags, flower-roots and ſeeds, books, maps and prints. The exports are raw and refined ſugars, train oil, copperas, a few cotton goods, ſome woollen goods, coffee, rice, and foreign merchandize of various kinds: their amount, as follows:

Years.	Imports.	Exports.
1800	£ 972,600	£ 3,208,613
1801	1,025,958	3,496,744
1802	974,537	4,957,997
1803	630,403	1,565,355

The total number of veſſels which entered inwards from Holland in the year 1804 was 790, and the number which cleared outwards 521. The number which entered inwards in 1805, was 709; outwards 323; which, from the two countries being at war, were of courſe nearly all neutral veſſels.

France poſſeſſes ſuch natural advantages in the produce of its ſoil, and the convenience of its ſituation for procuring the commodities of all other countries, that while its manufactures were encouraged, and it retained poſſeſſions in the Eaſt and Weſt Indies, little inducement remained for commercial intercourſe with Great Britain, and even this limited traffic was much impeded by the high duties and prohibitions which mutual jealouſy had impoſed. In 1786 a more liberal ſyſtem was adopted by a treaty of commerce, in conſequence of which the trade between the two countries increaſed conſiderably. In the year 1792, the exports to France amounted to 1,228,166*l.* 3*s.* 9*d.* of which 743,280*l.* 12*s.* 1*d.* was Britiſh manufactures, and 484,885*l.* 11*s.* 8*d.* foreign merchandize. In the following year, the trade with France was ſuſpended by war, on the termination of which, in 1802, commiſſioners were appointed for adjuſting the conditions of a new commercial treaty, but its completion was prevented by the renewal of hoſtilities.

The trade with *Portugal* was formerly a very beneficial branch of our commerce, but has declined very much. The imports conſiſt chiefly of wine, cotton-wool, and indigo, with conſiderable ſums in caſh and bullion. The exports are almoſt wholly Britiſh produce and manufactures.

Years.	Imports.	Exports.
1798	£ 700,383	£ 750,918
1799	1,047,054	1,073,411
1800	916,848	1,011,893

The total number of veſſels which entered inwards from Portugal in the year 1800 was 340, of which 270 were Britiſh veſſels. The number which entered inwards in the year 1806 was 468; outwards 332.

The extent of the trade with *Spain*, previous to the war in 1796, will appear from the ſtatement of imports and exports.

Years.	Imports.	Exports.
1792	£ 897,840	£ 794,101
1793	485,872	476,726
1794	748,546	634,554
1795	992,853	437,830
1796	809,881	546,126

The year 1806 being a year of war, the trade with Spain was of courſe confined to neutral veſſels: the number which entered inwards was 222, and the number which cleared outwards 126.

The *Mediterranean trade* was ſubject to much interruption during the war which began in 1793, in conſequence of which many of the goods uſually imported from Venice and Italy were brought over-land through Switzerland and Germany to Hamburgh and Tonningen to be ſhipped for England. The Turkey and Levant trade was formerly one of the principal branches of Engliſh commerce, but it is now of much leſs importance. The chief articles imported, are cotton-wool, mohair, goats' hair, opium, ſenna, and other drugs, galls, madder, vallonea, and other dye-ſtuffs, currants, figs, raiſins, goat ſkins, and box-wood; raw ſilk was formerly a principal article, but very little is now brought from Turkey, that of Italy being much ſuperior. The exports conſiſt of lead, tin-plates, wrought and caſt iron, hardware, a conſiderable number of watches, ſome cotton goods, and a few woollen goods, India piece goods, coffee, ſugar, cinnamon, cloves, pimento and other ſpices. The extent of the different branches of the Mediterranean trade will appear from the following ſtatements.

Gibraltar and the Streights.

Years.	Imports.	Exports.	Ships inward.	Ships outward.
1799	£ 62,992	£ 358,784	47	56
1800	35,665	294,558	20	43
1801	24,887	362,971	19	54
1802	21,792	530,537	32	48
1803	23,112	487,699	17	48
1804	33,860	560,399	27	62
1805	42,919	183,824	19	59

In the year 1806, the number of veſſels which entered inwards was 24, outwards 83.

Italy.

Years.	Imports.	Exports.	Ships inward.	Ships outward.
1799	£ 224,607	£ 367,173	69	81
1800	411,765	587,530	115	113
1801	165,042	378,007	44	94
1802	804,329	2,048,784	127	248
1803	748,020	656,607	182	74
1804	268,029	359,854	76	126
1805	393,517	507,535	106	117

In the year 1806, the number of veſſels which entered inwards was 90, outwards 61.

Malta.

Years.	Imports.	Exports.	Ships inward.	Ships outward.
1801	£ 11,448	£ 88,735	10	14
1802	16,698	12,023	36	4
1803	8,922	133,629	22	15
1804	32,913	114,031	20	23
1805	9,304	127,515	6	12

In the year 1806, the number of veſſels which entered inwards was 26, outwards 26.

Minorca.

Years.	Imports.	Exports.	Ships inward.	Ships outward.
1800	£ 13,500	£ 12,246	19	5
1801	6,768	36,130	16	15
1802	22,106	21,478	25	5

In the year 1803, the trade with Minorca ceaſed, from its having been reſtored to Spain.

Turkey and Levant.

Years.	Imports.	Exports.	Ships inward.	Ships outward.
1799	£ 33,091	£ 226,078	3	13
1800	199,773	166,804	19	6
1801	141,137	172,198	9	10
1802	182,424	180,000	20	18
1803	175,427	155,369	27	9
1804	148,277	81,625	16	1
1805	103,590	135,411	22	8

In the year 1806, the number of veſſels which entered inwards was 23, outwards 3.

The articles imported from the coaſt of *Africa* into Great Britain are gum arabic, gum ſandarach, and ſenegal, camwood, red-wood, ebony, ivory, a few oſtrich feathers, and ſome ſkins; their amount in the year 1800 was 82,289*l.* 8*s.* 8*d.* The exports have hitherto been of far greater value, being principally intended for the purchaſe of ſlaves for the Weſt Indies. They conſiſted of bugles, cowries, ſpiritous liquors, a great number of guns and cutlaſſes, gunpowder, wrought braſs, copper and iron, glaſs, earthen ware, rice, groceries, apothecaries' ware, woollen, cotton, and linen goods, and large quantities of India piece goods. The total official value in the year 1800 was 1,017,365 *l.* 11 *s.* 5 *d.* of which 521,922 *l.* 19 *s.* 11 *d.* was Britiſh merchandize. The abolition of the infamous traffick in human beings, muſt cauſe a great revolution in the trade to this part of the world, as it appeared in the year 1789 that about 38,000 of the inhabitants of Africa were annually carried away in Britiſh ſhips for ſupplying the colonies with ſlaves, which of courſe employed a conſiderable number of veſſels. The number of ſhips that cleared out from Great Britain for Africa, in the year 1804, was 176.

The *Eaſt India* trade furniſhes a remarkable inſtance of an extenſive branch of commerce carried on ſucceſſively in the hands of an excluſive company, while moſt other commercial monopolies have made very ſmall profits, and generally ſoon expired. The trade to India, however, ſince the immenſe territorial acquiſitions of the Engliſh in that part, can no longer be conſidered as a mere commercial adventure, as it is now in a great meaſure a buſineſs of agency, for tranſmitting to Europe the fortunes acquired by Britiſh individuals in the Eaſt. The quantity of merchandize brought from thence, conſequently, greatly exceeds the value of the exports to India. The latter conſiſts chiefly of woollens, metals, and naval and military ſtores, the remaining articles being of trifling amount in compariſon, and almoſt wholly for the uſe of Europeans, as the natives are peculiarly attached to the uſe of their own produce and manufactures. The exports to China include a conſiderable amount in bullion, the other articles are woollen cloths and camblets, lead, and tin; the articles exported in private trade are, ſkins and furs, glaſs of various deſcriptions, jewellery, toys, and watches, cuttings of cloth, a very few woollens, ſome cutlery and hard ware, and ſilver. The amount of the company's exports to India and China, will appear from the following ſtatements.

INDIA.

Seaſon.	Merchandize, or Manufacture.	Metals.	Stores.
1781	£ 200,808	£ 157,614	£ 163,878
1782	123,834	183,356	133,773
1783	95,251	122,855	77,237

1787	323,107	38,046	7,289	646,798
1788	335,392	59,208	6,598	489,192
1789	354,717	107,995	7,769	787,078
1790	431,385	105,707	4,081	532,705
1791	486,993	99,448	4,000	422,098

The imports from the Eaſt Indies conſiſt of Bengal piece-goods, coaſt and Surat piece-goods, Bengal and China raw-ſilk, tea, pepper, ſaltpetre, nankeen cloth, china, wrought ſilks, a ſmall quantity of china-ware, ſugar, coffee, indigo, and various drugs. The total amount of the imports, on the company's account, and in private trade, according to the official rates of the inſpector-general's office, was as follows:

Years.	Import.	Years.	Import.
1781	£ 2,526,339	1793	£ 3,499,023
1782	626,319	1794	4,458,475
1783	1,301,495	1795	5,760,810
1784	2,996,652	1796	3,372,689
1785	2,703,940	1797	3,942,384
1786	3,156,687	1798	7,626,930
1787	3,430,868	1799	4,284,805
1788	3,453,897	1800	4,942,275
1789	3,362,545	1801	5,424,441
1790	3,149,870	1802	5,794,906
1791	3,698,713	1803	6,348,887
1792	2,701,547	1804	5,214,621

But a more accurate idea of the real value of the imports from the Eaſt Indies, may be formed from the annual amount of the company's ſales, which was

In 1801	£ 7,595,181	In 1803	£ 6,042,526
1802	6,626,347	1804	5,866,073

The *Weſt India* trade is, in ſome reſpects, the moſt important branch of the commerce of Great Britain; as on the colonial produce which it ſupplies, much of the trade with different parts of Europe chiefly depends. The value of the Britiſh Weſt India produce from the old iſlands, imported into Great Britain, on a medium of four years, preceding the 5th of January 1796, according to the current prices during that period, was eſtimated, excluſive of the duties, at about 6,800,000 *l.* per annum. This ſum is not wholly a return for goods exported, a part of it muſt be conſidered as remittances of the property of perſons who poſſeſs eſtates in the Weſt Indies; but who are wholly or occaſionally reſident in England; and of perſons who have lent money on mortgage or otherwiſe in the Weſt Indies, and receive their intereſt from the ſale of the produce.

Official Value of Imports from the Weſt Indies.

Years.	Britiſh. Weſt Indies.	Conquered Iſlands.	Total.
1801	£ 6,759,617	£ 4,105,839	£ 10,865,456
1802	7,293,316	2,699,504	9,992,820
1803	5,786,432	362,014	6,148,436

The value of the Britiſh Weſt India iſlands, in a commercial view, will be very conſpicuous from the following ſtatement of the total quantities of ſugar, rum, coffee, and cotton-wool, exported from them.

Years.

Years.	Sugar. Cwt.	Rum. Galls.	Coffee. Cwt.	Cotton Wool. lbs.
1793	2,129,750	4,937,051	92,016	9 173,583
1794	2,141,921	5,597,520	141,007	8,473,175
1795	1,743,939	4,173,734	144,800	11.675,495
1796	1,816,584	5,567,754	94,086	8,854,413
1797	1,636,681	4,279,164	114,947	6,918,153
1798	2,015,602	6,224,076	165,075	7,909,832
1799	2,628.470	6,270,449	132,259	7,529,881
1800	2,413.997	6.231,225	180,374	10,611.349
1801	2,959,958	8,148,571	199,359	11,261,014
1802	3,463,366	8,676,381	230,148	8,799,891
1803	2,836,479	8,781,496	173,883	5,650,615

The total number of veſſels which entered inwards from the Weſt Indies, in the year 1804, was 721, containing 204,411 tons, and navigated by 12,119 ſeamen. The number of veſſels which cleared outwards was 790. The value of Britiſh produce and manufactures exported to the Britiſh plantations in the Weſt Indies, excluſive of the Conquered iſlands, was 3,408,232 *l.*

The trade with the United States of *America*, has rapidly advanced to very conſiderable importance; and Great Britain now ſupplies them with commodities to a far greater amount, than in the moſt favourable years previous to their independence, although the number of Britiſh ſhips employed is conſiderably leſs. In the year 1789 the number of Britiſh veſſels which entered inwards in this trade was 253, the number outwards 358; in the year 1799, the number which entered inwards was only 42, the number outwards 57.

Years.	Imports.	Exports.
1798	£ 1,782 720	£ 5.580,370
1799	1,818 941	7,056,558
1800	2,357,922	6,885,507

The total number of veſſels which entered inwards from the United States, in the year 1806, was 561, of which 53 were Britiſh; the total number which cleared outwards was 575, of which only 39 were Britiſh.

The remaining poſſeſſions of Britain in North America, being countries not very fertile or fully inhabited, the trade with them is not of very great extent. The following ſtatement of the exports to thoſe parts in the year 1800, will, however, ſhew that the trade is well worth preſerving, independent of the conſideration that it is the means of procuring articles of much importance in other branches of commerce.

To Hudſons bay - -	£	38,061	0	9
Newfoundland - -		219.458	5	11
Canada - - - - -		460,155	13	3
New Brunſwick - -		81,230	15	4
Nova Scotia - - -		177,083	17	10
Total	£	975,989	13	1

With reſpect to the general balance of trade, or the ultimate profit which Great Britain derives from its commerce with all other countries, Mr. Irving, the inſpector-general of imports and exports, to whom the public have, for many years, been indebted for the judicious arrangement and explanation of the official documents relating to foreign trade, has juſtly remarked, that there are perhaps few queſtions to which the human attention can be directed more difficult to form an opinion upon, from the variety of conſiderations, and the vaſt ſtatements with which it is connected, and alſo from the materials on which concluſions are to be formed, being in ſome inſtances defective; he has, however, ſtated it as his opinion, that the balance of trade in favour of Great Britain, according to the true value of the goods exported and imported, amounted on a medium of the four years preceding 1796, to upwards of 6,500,000 *l.* per annum, excluſive of the profits derived from the Eaſt and Weſt India trades, which he eſtimated at upwards of 400,000 *l.* per annum; and excluſive of the profits derived from the fiſheries.

An accurate view of the progreſs and extent of commerce in all the European ſtates, would furniſh much information; but with reſpect to ſeveral, no authentic particulars of this kind have been made public, and the foreign trade of others has been ſo entirely turned out of its uſual channels ſince the commencement of the war of the French revolution, that any account of its preſent ſtate would be very incomplete and unſatisfactory.

With reſpect to domeſtic commerce, we may obſerve, that the king is the arbiter of it; as it pertains to his prerogative to eſtabliſh public marts, as markets and fairs. to regulate weights and meaſures, and to give money, which is the univerſal medium of commerce, authority and currency.

A great part of the foreign commerce of England is now carried on by collective companies: ſome incorporated by the king's charters, with an excluſive privilege, as the Eaſt India company; others only private aſſociations, as the Turkey and Hamburgh companies. See COMPANY.

COMMERCE, *Chambers of.* See CHAMBER.

COMMERCE, *Characters in.* See CHARACTER.

COMMERCY, in *Geography*, a handſome town of France, and chief place of a diſtrict in the department of Meuſe, on the weſtern ſhore of that river. E. long. 5° 24'. N. lat. 48° 20'. It has a ſub prefect, and counts 3418 inhabitants. The diſtrict contains 181 communes, with a population of 73,103 individuals. There are ſeveral iron forges, paper mills, glue, violin, and linen manufactures.

COMMERSONA, in *Botany*. Sonnerat. See BARRINGTONIA.

COMMERSONIA, (ſo named by Forſter, in memory of M. Commerſon, the celebrated French naturaliſt and traveller.) Forſt. Gen. 22. Linn. jun. Supp. 26. Schreb. 535. Willd. 596. Lam. Ill. 550. Gært. 586. Juſſ. 428. Vent. 4. 17. Claſs and order, *pentandria pentagynia*. Nat. Ord. Undetermined; Juſſ. Vent.

Gen. Ch. *Cal.* one-leafed, five-cleft, bearing the petals between the ſegments; ſegments egg-ſhaped, acute, longer and broader than the petals. *Cor.* Petals five, dilated at the baſe on each ſide, with an inflexed lobe, ſpreading. *Stam.* Filaments very ſhort, ſituated at the baſe of the petals; anthers roundiſh, didymous. *Nectary* a five-cleft ring, between the petals and the germ, with five filiform villous ſmall bodies between the diviſions; diviſions lanceolate, erect, ſhorter than the petals. *Piſt.* Germ ſuperior, globular, villous, with five projections; ſtyles five, filiform, approximating, ſhort. *Per.* Capſule roundiſh, hard, echinate with long ſoft briſtle-ſhaped hairs, five-celled; two ſeeds in each cell. *Seeds* egg-ſhaped.

Eſſ. Ch. Calyx one-leafed, bearing the corolla. Petals five. Nectary five-cleft. Capſule five-celled, echinate.

Sp. C. *echinata.* Linn. jun. Supp. 26. Mart. Lam. Willd. Gært. tab. 94. Lam. Ill. tab. 218. (Reſtiaria; Rumph. Amb. 3. 187. tab. 119.) A middle-ſized tree. *Trunk* rarely the bulk of a man, with a diffuſe head and ſmooth bark, eaſily ſeparable from the wood; young branches woolly. *Leaves* alternate, petioled, obliquely egg-ſhaped, acuminate, ſerrated, a little wrinkled, ſhining, dark green above, hoary underneath. *Flowers* very ſmall, white, in axillary panicles. *Capſule* ſomewhat globular, with a coriaceous echinate rind, five-coccous, five-valved; cocci inverſely egg-ſhaped, narrowing downwards, ſemibilocular from the back, two-valved; valves of the contiguous cocci united and forming the proper partitions of the capſule. *Seeds* two in each cell, attached to the central angle of the cells, ovate-oblong, a little thicker upwards, ſlightly compreſſed, of a red-ferruginous colour, blackiſh at the top, incompleatly arilled; aril membranous, very thin, whitiſh, lacerated, fixed to the umbilicus of the ſeed, covering its whole ventral, but not its dorſal part. Gært. A native of Otaheite, the Friendly Iſles, and the Moluccas.

COMMIA, Boſc. Nouv. Dict. Claſs and order, *diœcia monandria*.

Gen. Ch. *Male catkins*. *Scales* obtuſe, each concealing a ſingle ſtamen. *Female catkins*. *Calyx proper* three-leaved; leaves acute, permanent. *Cor.* none. *Piſt.* Germ ſuperior; ſtyles three, ſhort; ſtigma thick. *Peric.* Capſule three-lobed, three-celled. *Seeds* one in each cell.

A tree. *Leaves* alternate, lanceolate, quite entire, ſmooth, recurved. *Flowers* in axillary and terminal catkins. A native of Cochin-china. A white gum exudes abundantly from its bark, which is ſometimes uſed as a medicine in dropſies and obſtructions, but is too violent in its effects to be taken without great caution.

COMMINATORY, a clauſe inſerted in a law, edict, patent, &c. importing a puniſhment wherewith delinquents are menaced; which, however, is not to be executed in its rigour.

Thus, in France, when an exile is enjoined not to return on pain of death, it is deemed a *comminatory* penalty; ſince, if he do return, it is not ſtrictly executed; but a ſecond injunction is then laid on him, which is more than comminatory, and from the day of the date thereof, imports death without remedy.

COMMINES, Philip de, in *Biography*, a celebrated hiſtorian, was born of a noble family in Flanders in 1445. He ſpent the early part of his life in the court of Charles the Bold, duke of Burgundy; but in 1472 he went over to the ſervice of Louis XI. king of France, who adopted him as a favourite, and employed him in various important negociations. He married an heireſs of the houſe of Anjou, by whom he acquired conſiderable landed property. He accompanied his ſovereign in many of his journies and in ſome expeditions of a more ſerious nature; and he attended upon his ſucceſſor Charles VIII. to the conqueſt of Naples. Under this prince he was accuſed of having eſpouſed the cauſe of the duke of Orleans, for which he was arreſted, and impriſoned in an iron cage for eight months. He was afterwards transferred to a priſon at Paris, where he was eighteen months without being able to obtain a trial. Commines was at length honourably acquitted, but it does not appear that, either in the remainder of this reign, or in that of the duke of Orleans who ſucceeded, and for whom he had ſuffered, he was afterwards publicly employed. He died, at his ſeat of Argenton, in Poitou, of which he had been denominated the lord. Commines poſſeſſed various qualities well adapted to render him eminent as a ſtateſman. He had a fine perſon, and an excellent underſtanding: he was a complete maſter of many modern languages, and had ſo great a command of his own powers that he could dictate to four ſecretaries at once. As a literary character he is chiefly known for his "Memoirs," which contain an account of the principal events of the reigns of Louis XI. and Charles VIII. during a period of thirty-four years. This work is highly eſteemed on account of the perſonal knowledge and obſervation of the author, who united a ſincere and candid diſpoſition, with a ſimple and unaffected ſtyle. By the learned Lipſius, Commines is regarded as equal to the hiſtorians of antiquity; his "Memoirs" he recommends as the vade mecum of princes. They have gone through many editions, which have been illuſtrated with notes by different learned men; but the moſt eſteemed impreſſion is that of the abbé Lenglet du Freſnoy, 1747, in 4 vols. 4to. printed at Paris, with London in the title page. Nouv. Dict. Hiſt. Du Freſnoi.

COMMINGES, in *Geography*, (in Latin *Convenæ*,) was before the French revolution of 1789, a county in the province of Gaſcony, and forms now part of the department of Haute-Garonne in France.

COMMINUTION, the act of grinding, or breaking any matter into ſmaller particles.—The effect of chewing, or maſticating our food, is the *comminution* thereof.

COMMIRE, John, in *Biography*, a Jeſuit, was born in 1625 at Amboiſe, where his father kept a tennis-court. He received a good education, and applied himſelf chiefly to claſſical literature. He acquired great reputation as a poet, by a collection of pieces in Latin which appeared in 1678, but he was, at the ſame time, diligent in his profeſſion, as a teacher and director in theology. His poems conſiſt of paraphraſes on various parts of the ſcriptures, odes, fables, epigrams, &c. of which the general character is facility, copiouſneſs, and amenity. He is thought to have ſucceeded beſt in his odes, but his fables are in high repute. He died at Paris in 1702, leaving behind him the character of an open and upright diſpoſition. An edition of his poems was publiſhed in 2 vols. 12mo. in the year 1754. Nouv. Dict. Hiſt.

COMMIS, Fr. A clerk, deputy, or ſubordinate perſon, who is employed in any of the war-departments of the French.

Commis *general du parc des vivres*; commis-general of the proviſion-park. This officer exerciſes his functions under the orders of the director-general of proviſions. His employment requires a good deal of capacity and zeal, as well as of probity. His duties and relations are multifarious and extenſive. He ſhould always encamp in the centre of the baggage, to be able to have an eye to the whole, and to be leſs interrupted.

Commis *General des travaux du parc des vivres*, commiſ-general of labour and work in the proviſion-park. The duties of this employment are troubleſome, and require much attention. It ſhould never be beſtowed on a man that does not poſſeſs experience, prudence, and firmneſs, without being too rigorous or ſevere, as he has authority over every thing connected with the different kinds of work in the park.

Commis *des entrepreneurs pour la fourniture des lits*; clerks of undertakers for the furniſhing of beds. They have a right to viſit and examine the beds and every thing connected with them, and to refuſe or reject whatever is inſufficient or defective.

Commis *du treſorier de l'extraordinaire des guerres*, clerks of the treaſurer of the wars, or of the paymaſter general of the army. They deliver the certificates to the troops who leave lodgings or quarters. They were under the juriſdiction of the high conſtable.

COMMISERATION, in *Pathology* and *Ethics*, is frequently uſed as ſynonymous with *compaſſion*, which ſee; but, in its general uſe, it is ſomewhat different. It is always preferred, when we wiſh to expreſs our ſympathy for misfortunes, which it is not in our power to remove, or for which there is no apparent remedy. Commiſeration, ruminating upon the ſtate and ſuffering of others, induces a permanent concern. In ſuch caſes it may be ſaid, that we commiſerate the unfortunate ſufferer, rather than that we have compaſſion upon him. But although this is a more helpleſs, it is not an uſeleſs affection. It ſooths the mind of the afflicted, and greatly alleviates their ſorrows, when every other conſolation fails. *Condolence* is the expreſſion of our commiſeration. Cogan on the Paſſions, p. 134.

COMMISSAIRE, Fr. *Commiſſary*. This word or term was uſed in the old French ſervice, to expreſs a variety of occupations, and was annexed to a good many different appellations, of which the following are the principal.

Commissaire *General des Guerres ou commiſſaire General des Armées*, commiſſary general of the wars. This charge, office, or appointment, was created for *Beſançon*, in 1637, and did not long exiſt, being ſuppreſſed in his perſon, becauſe it gave too much authority, and too many privileges, to the perſon inveſted with it.

Commissaire *Général de la Cavalerie légère*. Fr. He was the third general officer of all the regiments of cavalry, and he had a regiment of his own under the name of the regiment of the *commiſſaire général*, or commiſſary general.

Commissaire *Ordonnateur des Guerres*. This appointment was ſuperior to that of an ordinary or provincial commiſſary of war. It was commonly a ſort of recompence and advancement granted in conſideration of ſervices rendered by the one or the other commiſſaries of war, whether of the armies or in the interior of the ſtate. The *commiſſaire ordonnateur* is charged with objects of the firſt importance, and with a greater variety of them than the other commiſſaries are.

Commissaires *des Guerres*, commiſſaries of the wars, or muſter-maſters general. They enjoyed peculiar privileges, but were ſubordinate to the governors and commandants of towns and garriſons, without whoſe permiſſion they could not muſter any regiment.

Commissaires *Ordinaires des Guerres*, ordinary commiſſaries of the wars, or deputy-muſter maſters. Officers ſubordinate to the immediately preceding, who ought to aſſiſt at reviews, who are charged with the conduct, police, and diſcipline of troops, and with making the men obſerve the military decrees. With the army, they have the detail of the hoſpitals, bread, victuals, &c. &c. They make inventories of proviſions, and are charged with the management of convoys. Their creation is very ancient: for there is mention made of them under the reign of king Jean I. in 1355. They were called at firſt *conducteurs des gens de guerre*, (conductors of the people of war, or of military people) a title or appellation which they enjoyed for a long time under Louis XIII., and they are ſtill called ſo in their commiſſions. Thoſe who were not gentlemen, had the right of taking the rank of ſquire, or eſquire; of enjoying all the privileges of the nobleſſe, and of acquiring noble fiefs.

Commissaire *Provincial des Guerres*, provincial commiſſary of the wars. There were no *commiſſaires provinciaux des guerres* before the year 1635. They were afterwards ſuppreſſed, and were re-eſtabliſhed in 1704, under Louis XIV., with the ſame privileges, rights, attributions, and authorities for the ſervice of cities of war, that the ordinary commiſſaries of the wars enjoyed for the ſervice of marches, and of the armies.

Commissaire *General des Vivres*, commiſſary general of proviſions. This officer has under him ſeveral other commiſſaries, who ought to know the number of men, which each of them will have to ſubſiſt, in order to make choice of a proper place for cauſing the proviſions to be brought to, as alſo to form magazines for the duration of the campaign, and of courſe to procure a ſufficient number of bakers and workmen.

Commissaire *d'Artillerie*, commiſſary of artillery. There is one ſuch officer in each department of the ordnance, who keeps one of the three keys that belong to the artillery-magazine. It is at his requiſition that the governor or commandant of a place ſends ſoldiers to remove, when neceſſary, the pieces of artillery and ſtores of war. He has the ſuperintendance and direction of every thing connected with the cleanlineſs and general management of the magazines.

Commissaires *provinciaux d'Artillerie*, provincial commiſſaries of artillery. Theſe were of two ſorts or deſcriptions. The one had the names or titles of the provinces; the other had merely the title of provincial. But on ſervice, they both received the ſame pay.

Commissaires *ordinaires d'Artillerie*, ordinary commiſſaries of artillery. Theſe were ſubordinate to the provincial commiſſaries, and were diſtributed among the forts, garriſoned towns, navy, and dockyards.

Commissaires *extraordinaires d'Artillerie*, extraordinary commiſſaries of artillery. Under the monarchy of France, theſe formed the third of ordnance-commiſſaries, and they were in like manner diſtributed on duty in garriſoned places, and on board ſhips of war.

Commissaire *provincial en l'Arſenal de Paris, ax department de l'Iſle de France*, provincial commiſſary in the arſenal of Paris, in the department of the iſle of France. This officer received his commiſſion from the grand maſter, in whoſe gift it was, and poſſeſſed the excluſive privilege of being made privy to every alteration or movement that took place in the arſenal.

Commissaire *General des Poudres et Saltpetres*, commiſſary general of gun-powder and ſaltpetre. This appointment was created in 1634, with that of ſuperintendant general of gun-powder and ſaltpetre. It was at laſt ſuppreſſed, and the grand maſter of the ordnance appointed a perſon to exerciſe its functions.

Commissaire *General des Fontes*, commiſſary general of the founderies. This appointment was the gift of the maſter of the ordnance, and was invariably beſtowed on thoſe who had given convincing proofs of their abilities and ſkill in the caſting of cannon, &c.

Commissaires *des Guerres entretenus dans l'Hotel des Invalides*, commiſſaries of war kept in the *hotel des invalides*. It was a principal part of their duty to keep a regular roll or liſt of all the names of the different officers, non-commiſſioned officers, and ſoldiers, that might be detached on garriſon duty, &c. from which they made a monthly return to the ſecretary at war. Each commiſſary, at every review or inſpection of the corps of invalids, had particular directions to mark and point out thoſe men who appeared to be capable of ſerving, of whom a regular return was made to the ſecretary at war.

Commissaire *General des Fortifications*, commiſſary general of fortifications. This was an office of great importance, as it was his duty to give the plans for places and new works; to approve or condemn thoſe that had been ordered by others; to viſit the fortified places of the kingdom; to order the reparation of works that had been damaged; to regulate the conduct of the engineers, and to give them orders for the good of the ſervice.

At a ſiege, he directed the tracing out of the lines of circumvallation and countervallation, and the ſecuring of the poſts; he decided on attacks which were made according to his plan; he directed the making of lodgments, ſaps, mines, the traverſe of the ditch, the attack of the breach, and after the place was taken, cauſed it to be repaired. In defending a place, he had the ſame or equal power. His appointments amounted to about 30,000 livres per annum.

COMMISSARY, in *Military Language* of Britain, has various denominations, though he is generally a civil officer appointed to inſpect the muſters, ſtores, and proviſions for the army. The number of ſuch officers is not limited in time of war.

Commiſſaries *general*, and commiſſaries *of accounts*, in our ſervice, are appointed by warrant under the king's ſign manual, directing them to obey all inſtructions given to them for the execution of their duty by the lords commiſſioners of the treaſury. Theſe inſtructions are generally prepared by the comptrollers of the army-accounts, under the orders of the treaſury, and ſubject to its ſubſequent inſpection.

Commissary *General of the Muſters*, or *Muſter-maſter general.* This officer takes an account of the ſtrength of every regiment as often as he pleaſes; reviews them; ſees that the horſe are well mounted, and that all the men are well armed and clothed. He receives and inſpects the muſter-rolls, and thereby knows exactly the ſtrength of the army. A new officer has been appointed under the appellation of *Inſpector-general of Cavalry*, who performs the duties in that reſpect, which uſed to be performed by the muſter-maſter general.

Commissary *General of Stores.* A civil officer who has charge of ordnance ſtores, for which he is accountable to the office of ordnance. He has other commiſſaries under him, as well as clerks and conductors, particularly in time of war.

Commissary *of the Train-horſes.* A civil officer of the ordnance, who has the inſpection of all horſes belonging to the train of artillery, the hoſpital, and the bakery. He has a number of conductors, drivers, &c. under him.

Commissary *of Accounts.* A perſon of reſponſibility, who, with a proper eſtabliſhment, attends each army, ſufficiently large and numerous to render it neceſſary for the purpoſe of taking, examining, and controlling accounts on the ſpot. All ſuch commiſſaries make returns of their examinations, on which, as documents, the comptrollers of the army-accounts ground their inquiries into that branch of the public expenditure.

Commissary *General of Proviſions.* An officer who is charged with furniſhing the army in the field and on ſervice, with all ſorts of proviſions; forage, &c. generally by contract, and ſometimes otherwiſe. He has a variety of commiſſaries, ſtore-keepers, clerks, &c. under him.

Commissary, in the *Eccleſiaſtical Law*, an officer of the biſhop, who exerciſes eccleſiaſtical juriſdiction in thoſe parts of the dioceſe, which are ſo remote from the ſee, that the chancellor cannot call the ſubjects thereof to the biſhop's principal conſiſtory, without their too great moleſtation.

This officer, called by the canoniſts *commiſſarius*, or *officialis foraneus*, is appointed to ſupply the biſhop's office in the out-parts of the dioceſe, and in ſuch parts as are peculiar to the biſhop, and exempted from the juriſdiction of the archdeacon: for where the archdeacons have juriſdiction, as in moſt places they have, either by preſcription or compoſition, the commiſſary is ſuperfluous, and frequently vexatious, and ought not to be: yet in ſuch caſes, a commiſſary is ſometimes appointed by the biſhop, and takes preſtation-money of the archdeacon yearly *pro exteriori juriſdictione*, as it is ordinarily called. But this is held to be a wrong to archdeacons and the poorer ſort of people. Cowel's Interp. 4 Inſt. 338.

Commissary *Court*, in *Scots Jurisprudence.* At the reformation, all epiſcopal juriſdiction exerciſed under the authority of the biſhop of Rome was aboliſhed; and the courſe of juſtice in conſiſtorial cauſes was thus ſtopped. Hence queen Mary, beſides naming a commiſſary for every dioceſe, did, by a ſpecial grant, eſtabliſh a new *commiſſary-court* at Edinburgh, conſiſting of four judges or commiſſaries. This court is veſted with a double juriſdiction; one dioceſan, which is exerciſed in the ſpecial territory contained in the grant, *viz.* the counties of Edinburgh, Haddington, Linlithgow, Peebles, and a great part of Stirlingſhire; and another univerſal, by which the judges confirm the teſtaments of all who die in foreign parts, and may reduce the decrees of all inferior commiſſaries, provided the reduction be purſued within a year after the decree. Biſhops, upon their re-eſtabliſhment in the reign of James VI., were reſtored to the right of naming their ſeveral commiſſaries. The commiſſaries retain to this day an excluſive power of judging in declarations of marriage, and of the nullity of marriage; in actions of divorce and of non-adherence, of adultery, baſtardy, and confirmation of teſtaments; becauſe all theſe matters are ſtill conſidered to be properly conſiſtorial. Inferior commiſſaries are not competent to queſtions of divorce, under which are comprehended queſtions of baſtardy and adherence, when they have a connection with the lawfulneſs of marriage, or with adultery. Commiſſaries have now no power to pronounce decrees in abſence for any ſum above 40*l.* Scots, except in cauſes purely conſiſtorial; but they may authenticate tutorial and curatorial inventories: and all bonds, contracts, &c. which contain a clauſe for regiſtration in the books of any judge competent, and proteſts on bills, may be regiſtered in their books.

COMMISSION, in *Common Law*, is the ſame with *delegatio* among the civilians; and is taken for the warrant, or letters-patent, which all perſons exerciſing juriſdiction, either ordinary or extraordinary, have to authoriſe them to hear or determine any cauſe or action: ſuch as the commiſſion of judges, &c.

The term, however, is ſometimes extended farther than to matters of judgment; as in the commiſſion of purveyors, which ſeems to be null by the ſtatute for taking away purveyance, 12 Car. II. and the high commiſſion court, which was founded on the ſtatute 1 Eliz. and is alſo aboliſhed by act of parliament 16 Car. I. The perſons charged with a commiſſion are hence called *commiſſioners*; ſometimes *committees.*

Commiſſions of inquiry ſhall be made to the juſtices of one bench or the other, &c., and to do lawful things are grantable in many caſes. Moſt of the great officers, judicial and miniſterial, of the realm, are made by commiſſion. And by ſuch commiſſions, treaſons, felonies, and other offences, may be heard and determined; by this method, likewiſe, oaths, cognizances of fines, and anſwers, are taken, witneſſes examined, offices found, &c. Bro Ab. 12. Rep. 39. See ſtat. 42 E. III. c. 4. Moſt of theſe commiſſions are appointed by the king under the great ſeal of England; but a commiſſion under the grand ſeal may be determined by a privy ſeal; and by granting another new commiſſion to do the ſame thing, the former commiſſion determines; and on the death or demiſe of the king, the commiſſions of judges and officers generally ceaſe. Bro. Commiſ. 2 Dyer 289.

Commission *of Anticipation*, was anciently a commiſſion given under the great-ſeal, to collect a tax or ſubſidy before the day. 15 Hen. VIII.

Commission *of Array.* See Militia.

Commission *of Aſſociation*, is a commiſſion under the great ſeal to aſſociate two, or more learned perſons, with the ſeveral juſtices, in the ſeveral circuits and counties in Wales.

Commission *of Bankruptcy*, a commiſſion under the great ſeal, directed to five or more commiſſioners, to enquire into the particulars of a man's circumſtances, who hath failed, or broke; and to act according to certain ſtatutes made in that behalf. See Bankrupt, and Petition *of Bankruptcy*.

Commissions *of Charitable Uſes* go out of the chancery to the biſhop and others, where any lands given to charitable uſes are miſemployed, or there are any fraud or diſputes concerning them, to enquire of and redreſs the abuſe, &c. 43 Eliz. cap. 4.

Commission *of Delegates*, a commiſſion under the great ſeal to certain perſons, uſually two or three temporal lords, as many biſhops, and two judges of the law, to ſit upon an appeal to the king in the court of chancery, where any ſentence is given in any eccleſiaſtical cauſe by the archbiſhop. Stat. 25 Hen. VIII. c. 19. Now generally three of the common law judges and two civilians ſit as judges. See Court and Delegates.

Commission *to enquire of faults againſt the law*, an ancient commiſſion ſet forth on extraordinary occaſions and corruptions.

Commission *of Lunacy*, a commiſſion out of chancery to enquire whether a perſon repreſented to be lunatic, be ſo or not; that, if lunatic, the king may have the care of his eſtate, &c. 17 Edw. II. c. 10.

Commission *of Peace*. See Justice *of Peace*.

Commission *of Rebellion*, or *Writ of Rebellion*, is iſſued out when a man, after proclamation made by the ſheriff upon a proceſs out of the chancery, to preſent himſelf, under pain of his allegiance, to the court by a certain day, does not appear. See Rebellion.

This commiſſion is directed by way of command to certain perſons; three, two, or one of them; to apprehend, or cauſe to be apprehended, the party as a rebel; and to bring him to the court on a day aſſigned.

This writ or commiſſion goes forth after an attachment returned, *non eſt inventus*, &c.

Commission *of Sewers*, is directed to certain perſons to ſee drains and ditches well kept, and maintained, in the marſhy and fenny parts of England, for the better conveyance of water into the ſea, and preſerving the graſs upon the land. Stat. 23 Hen. VIII. c. 5. 13 Eliz. c. 9. The ſtat. 3 Jac. I. c. 14. ordains, that all ditches, water-courſes, &c. within two miles of London, falling into the Thames, ſhall be ſubject to the commiſſion of ſewers; and the lord-mayor, &c. is to appoint perſons who have this power. 7 Ann. c. 10.

Commission *to examine witneſſes*, is ſometimes appointed by the court of equity in caſes that require it, as when the cauſe ariſes in a foreign country, and the witneſſes are at home, or when the witneſſes are abroad, or ſoon to leave the kingdom; or again, when they are aged and infirm. This commiſſion is empowered to exerciſe the ſame juriſdiction as would have been exerciſed if the witneſſes had attended. See Suit.

Commission *of Treaty with Foreign Princes*, is where leagues and treaties are made and tranſacted, between ſtates and kingdoms, by their ambaſſadors and miniſters, for the mutual advantage of the kingdoms in alliance.

Commission *to take up Men for War*, was a commiſſion to preſs or force men into the king's ſervice. This power of impreſſing has been heretofore doubted; but the legality of it is now fully eſtabliſhed. Foſt. Rep. 154. Blackſt. Com. p. 419. Cowp. 517. See Impressing.

Commission, *Militaire*. A brevet, or power, granted in writing by the miniſter of war in the name of the ſovereign, and ſealed with the great ſeal, by which he, to whom it is given, exerciſes the military charge entruſted to him, and takes his rank from the day of the date thereof. Commiſſion in a military ſenſe, in our ſervice, denotes any ſituation or place, which an individual may hold in the regular army, militia, or volunteers. All commiſſions in the line, guards, or volunteer-corps, muſt have the royal ſign manual. Commiſſions however in the militia do not bear the royal ſign manual, except that of the adjutant, who is commonly called a king's officer. The lieutenants or deputy-lieutenants of counties affix their ſeals and ſignatures to militia-commiſſions after they have been laid before the king for his approbation. Fourteen days conſtitute the time allotted for the royal approbation or diſapprobation. And if his majeſty does not within that time *diſapprove* of the perſon ſo recommended, a notification of his pleaſure and acquieſcence is ſent by one of the principal ſecretaries of ſtate to the lord lieutenant or to thoſe acting by commiſſion in his abſence.

Commission *Militaire* is alſo a momentary or temporary tribunal appointed or ordered to ſit for the trial of military crimes and offences. When judgment is pronounced and the duty is performed, for which it was appointed, its authority, as well as its exiſtence, ceaſes.

Commissions *of Array*. Commiſſions iſſued to experienced officers to draw out and array the fitteſt men in each county for ſervice, and to march them to the ſea coaſts, or to ſuch other parts of the county as were thought to be moſt in danger. There were hundreds of ſuch commiſſions between the 36th of Henry III., and the reign of Edward IV. The form of one is to be ſeen in "Ruſhworth's Hiſtorical Collection," publiſhed in 1640. Such commiſſions were attempted to be revived by Charles I.; but they were voted illegal and unconſtitutional by the parliament.

Non-commiſſioned is a term commonly employed to denote a claſs of men, who ſtand between the rank and file of a battalion, and the commiſſioned and warrant officers, as ſerjeants-major, ſerjeants for inſtance.

Commission-*Officers*. See Officer.

Commissions, *Book of*. See Book.

Commission, in *Commerce*. See Factorage.

COMMISSIONER, he who has a *commiſſion*, *e. gr.* a patent, or other legal warrant, to execute any public office. See Warrant, &c.

Such are, *commiſſioners* of hawkers and pedlars, *commiſſioners* of alienation, *commiſſioners* of the ſtamps, &c.

Commissioners *of Public Accounts*. See Accounts.

Commissioners *of the Cuſtoms*. See Custom-*houſe*.

Commissioners *of the Dock-yards*. See Dock-*yards*.

Commissioners *of Exciſe*. See Excise.

Commissioners *of the Navy*. See Navy.

Commissioners, *Lords, of the Treaſury*. See Treasury, and Exchequer.

Commissioners *of Trade*, &c. See Board.

COMMISSUM *Fidei*. See Fidei.

COMMISSURE, Commissura, a term uſed by ſome authors for the junctures, or for the ſmall interſtices of bodies; or the little clefts between the particles; eſpecially when thoſe particles are broadiſh or flat, and lie contiguous to one another, like thin plates, or *lamellæ*.

The word literally ſignifies *a joining*, or connecting of one thing to another.

Commissure, in *Architecture*, &c. denotes the joint of two ſtones; or the application of the ſurface of the one to that of the other.

COMMISSURÆ *Cerebri*, in *Anatomy*, are parts of the brain, which join together the right and left ſides of this viſcus.

There are three of theſe commiſſures: an anterior one which is directly under the anterior crura of the fornix; a poſterior, which is behind the optic thalami, and in front of the tubercula quadrigemina; and a middle one, which joins together the oppoſed convexities of the thalami nervorum opticorum. For a further deſcription of theſe parts, ſee Brain.

COMMITMENT, in *Law*, the ſending of a perſon to priſon by warrant or order, who hath been guilty of any offence not bailable, or for which bail is refuſed. It may be by the king and privy council, or ſecretary of ſtate, by the judges of the law, juſtices of peace, and other magiſtrates, who have authority by the laws and ſtatutes of the realm to do it, which muſt be exactly purſued.

As to the manner of commitment, it is enacted by 2 & 3 P. & M. c. 10., that juſtices of peace ſhall examine perſons brought before them for felony, &c. or ſuſpicion thereof, before they commit them to priſon, and ſhall bind their accuſers to give evidence againſt them. A juſtice of the peace may detain a priſoner for examination, and it is ſaid that three days are a reaſonable time for this purpoſe. 2 Hawk. P. C. c. 16. § 11, 12. Dalt. c. 125. 2 Inſt. 52, 591.

Every commitment muſt be in writing, under the hand and ſeal, and ſhew the authority, of him that made it, and the time and place, and muſt be directed to the keeper of the priſon. It may be either in the king's name, and only teſted by the juſtice, or in the name of the juſtice. It may command the gaoler to keep the party in ſafe and cloſe cuſtody, which he is bound by law to do. 2 Hawk. P. C. c. 16. § 13, 14, 15. It ought to ſet forth the crime with convenient certainty, whether the commitment be by the privy council, or by any other authority; otherwiſe the officer is not puniſhable by reaſon of ſuch mittimus, for ſuffering the party to eſcape; and the court before which he is removed by Habeas-corpus, ought to diſcharge or bail him; and this holds not only where no cauſe at all is expreſſed in the commitment, but alſo where it is ſo looſely ſet forth, that the court cannot judge whether it were a reaſonable ground for commitment or not. 2 Hawk. P. C. c. 16. § 17. See Arrest and Bail. A commitment for high treaſon or felony in general, without expreſſing the particular ſpecies, has been held good. (2 Hawk. P. C. c. 16. § 16.) But now, ſince the Habeas-corpus act, it ſeems that ſuch general commitment is not good. Moreover, it is ſafe to ſet forth that the party is charged upon oath; but this is not neceſſary, for it hath been reſolved, that a commitment for treaſon, or for ſuſpicion of it, without ſetting forth any particular accuſation or ground of the ſuſpicion, is good. 2 Hawk. P. C. c. 16. § 17. Every ſuch mittimus ought to have a lawful concluſion, *viz.* that the party be kept till he be delivered by law, or by order of law, or by due courſe of law; or that he be kept till further order (which ſhall be intended of the order of law) or to the like effect; and if the party be committed only for want of bail, it ſeems to be a good concluſion of the commitment, that he be kept till he can find bail; but a commitment till the perſon who makes it ſhall take further order, ſeems not to be good: and it ſeems that the party committed by ſuch or any other irregular mittimus, may be bailed. 2 Hawk. P. C. c. 16. § 18.

A commitment grounded on an act of parliament ought to be conformable to the method preſcribed by ſuch ſtatute. Where a man is committed as a criminal, the concluſion muſt be, "until he be delivered by due courſe of law;" if he be committed for contumacy, it ſhould be "until he comply."

All commitments muſt be to ſome priſon within the realm of England; for by the Habeas-corpus act (ſtat. 31 Car. II. cap. 2.) it is enacted "that no ſubject of this realm, being an inhabitant or reſiant of this kingdom of England, dominion of Wales, or town of Berwick-upon-Tweed, ſhall or may be ſent priſoner into Scotland, Ireland, Jerſey, Guernſey, Tangier, or into any ports, garriſons, iſlands or places, beyond the ſeas, which then were, or at any time after ſhould be, within or without the dominions of his majeſty." By ſtat. 14 Ed. III. c. 10, ſheriffs ſhall have the cuſtody of the gaol as before that time they were wont to have, and they ſhall put in ſuch under keepers for whom they will anſwer. This is confirmed by ſtat. 19 Hen. VII. c. 10. It hath alſo been held, that regularly no one can juſtify the delivering of a priſoner in cuſtody out of the common gaol, unleſs there be ſome particular reaſon for ſo doing, as ſickneſs endangering life, or evident danger of a reſcous from rebels, &c.: nevertheleſs conſtant practice ſeems to authorize a commitment to a meſſenger; and it is ſaid, that it ſhall be intended to have been made in order for the carrying of the party to gaol. 2 Hawk. P. C. c. 16. § 8, 9. And it is ſaid, that if a conſtable bring a felon to gaol, and the gaoler refuſe to receive him, the town where he is conſtable ought to keep him till the next gaol delivery. H. P. C. 114. 2 Hawk. P. C. c. 16, § 9. A priſoner in the cuſtody of the king's meſſenger, on a warrant from the ſecretary of ſtate, who is brought into K. B. by Habeas-corpus to be bailed, but has not his bail ready, cannot be committed to the ſame cuſtody, under which he came; but muſt be committed to the cuſtody of the marſhal, which will prevent the neceſſity of ſuing out a new Habeas corpus; as he may be brought up from the priſon of the court, by a rule of court, whenever he ſhall be prepared to give bail. 1 Burr. 460. If a perſon arreſted in one county for a crime done in it, fly into another county, and be retaken there, he may be committed by a juſtice of the firſt county to the gaol of ſuch county. (H. P. C. *93.*) But by the better opinion, if he had, before any arreſt, fled into ſuch county, he muſt be committed to the gaol thereof by a juſtice of ſuch county. 2 Hawk. P. C. c. 16. § 8. Dalt. c. 118. It ſeems alſo to be laid down as a rule by ſome books, that any offender may be committed to the gaol next to the place where he was taken, whether it be in the ſame county or not. 2 Hawk. P. C. c. 16, § 8. By ſtat. 6 Geo. I. c. 19. vagrants and other criminals, and perſons charged with ſmall offences, may, for ſuch offences, or for want of ſureties, be committed either to the common gaol or houſe of correction, as the juſtices ſhall think proper. By ſtat. 24 Geo. II. c. 55. if a perſon is apprehended, upon a warrant indorſed, in another county, for an offence not bailable, or if he ſhall not there find bail, he ſhall be carried back into the firſt county, and be committed, or if bailable, bailed by the juſtices in ſuch firſt county.

With reſpect to the charges of commitment, it is enacted by ſtat. 3 Jac. I. c. 10, that offenders committed are to bear their own charges, and the charges of thoſe who are appointed to guard them; and if they refuſe to pay, the charges may be levied by ſale of their goods. And by ſtat. 27 Geo. II. c. 3. if they have no goods, &c. within the county where they are apprehended, the juſtices are to grant a warrant on the treaſurer of the county for payment of their charges. But in Middleſex the ſame ſhall be paid by the overſeers of the poor of the pariſh where the perſon was apprehended. By ſtat 3 Hen. VII. c. 3. the ſheriff ſhall certify the names of all priſoners in his cuſtody to the juſtices of gaol delivery.

Priſoners, committed at firſt to the proper priſon, ought not to be removed thence, except in ſome ſpecial caſes; and in peculiar circumſtances, ſpecified by 31 Car. II. c. 2. A perſon, legally committed for a crime, which certainly appears to have been done by ſome one or other, cannot be lawfully diſcharged by any other but the king, till he be acquitted on his trial, or have an *ignoramus* found by the grand jury, or none to proſecute him on a proclamation for that purpoſe, by the juſtices of gaol-delivery. But if a perſon be committed on a bare ſuſpicion, without any appeal or indictment, for a ſuppoſed crime, when afterwards it appears there was none; as for the murder of a perſon thought to be dead, but afterwards found to be alive, it hath been held that he may be ſafely diſmiſſed without any farther proceeding. 2 Hawk. P. C. c. 16. § 22. But the ſafeſt way for the gaoler is to have the authority of ſome court, or magiſtrate, for diſcharging the priſoner. If the words of a ſtatute are not purſued in a commitment, the party ſhall be diſcharged by Habeas-corpus. Jacob's Law Dict. by Tomlins. See Arrest, Bail, Imprisonment, Mittimus, &c.

COMMITTEE, in *Law*, one or more perſons, to whom the conſideration of any matter is referred, either by a court, or by conſent of the parties concerned.

Committee *of Parliament*, is a board conſiſting of a certain number of members, appointed by the whole houſe for the examining of a bill, or making report of an inquiry, or proceſs of the houſe, &c.

Sometimes the whole houſe is reſolved into a *committee*; on which occaſion each perſon has a right to ſpeak, and reply as much, and as often as he pleaſes; an expedient they uſually have recourſe to in extraordinary caſes, and where any thing is to be thoroughly canvaſſed. When the houſe is not in a *committee*, each gives his opinion regularly, and is only allowed to ſpeak once, unleſs to explain himſelf.

The ſtanding *committees*, appointed by every new parliament, are thoſe of *privileges* and *elections*, of *religion*, of *grievances*; of *courts of juſtice*, and of *trade*, though only the former act. See Parliament.

Committee *of the king*, is uſed for a widow of one of the king's tenants; thus called, as being by the ancient law of the realm *committed* to the king's care and protection. See Widow.

Committee of a *Lunatic*, *Ideot*, &c. denotes the perſon to whom the care and cuſtody of ſuch lunatic, &c. is committed by the court of chancery. See Lunatic.

Committees of *Corporations*, &c. are ſelect members who perform the general routine of buſineſs. See Corporations.

COMMODATE, Commodatum, in the *Civil Juriſprudence*, the loan or free conceſſion of any thing moveable or immoveable, for a certain time on condition of reſtoring again the ſame individual after a certain term.

The commodate is a kind of loan; there is this difference, however, between a loan and a commodate, that the latter is gratis, and does not transfer the property: the thing muſt be returned in eſſence, and without impairment: ſo that things which conſume by uſe, or time, cannot be objects of a commodate, but of a loan; in regard they may be returned in kind, though not in identity.

COMMODAVIENSIS, an appellation given by ſome authors to a ſpecies of *lapis calaminaris* found in Bohemia. But as it yields no zinc, Mr. Marggraff denies it to be true calamine.

COMMODITIES, *Staple*. See Staple.

COMMODORE, in the *Britiſh Marine*, a general officer inveſted with the command of a detachment of ſhips of war deſtined on any particular enterprize; during which time he bears the rank of a brigadier-general in the army; and his ſhip is diſtinguiſhed by a broad red pendant tapering towards the outer end, and ſometimes forked.

Commodore is alſo a name given to a ſelect ſhip in a fleet of merchantmen, which leads the van in time of war, bearing a light in her top to conduct the reſt.

COMMODUS, Lucius Aurelius Antoninus, in *Biography*, was the only ſon of the emperor Marcus Antoninus and Fauſtina, and born A. D. 161. He was educated with the utmoſt attention, and he enjoyed very ſuperior advantages from the precepts and inſtructions of tutors appointed to preſide over his infantile ſtudies and purſuits; but from the firſt openings of his mind, he diſplayed an untoward diſpoſition, and a ſtrong propenſity for low and unworthy gratifications. He diſcovered an averſion from whatever was rational ar[illegible]ral, and a fond attachment to the ſports of the c[illegible] amphitheatre, the combats of gladiators, and the hunting and deſtroying of wild beaſts. To wean him from theſe purſuits, and with a view of engaging his mind in uſeful and manly occupations, his father made him a partaker of the ſovereign power in his fifteenth year. This inſtance of parental affection did not produce the deſired effect; it only furniſhed him with better opportunities of indulging every ſenſual gratification. Upon the death of Marcus, in the year 180; he ſucceeded to the quiet and undiſputed poſſeſſion of the throne; he ſaw about him neither competitor to remove nor enemies to puniſh, and during the firſt three years of his reign, the influence of his father's virtuous counſellors reſtrained him from any acts of tyranny towards his ſubjects. During this period, however, he indulged in every ſpecies of licentiouſneſs, and revelled in all the licence of ſovereign and unreſtrained power, but his hands were unſtained with blood, and occaſionally he diſplayed a generoſity of ſentiment worthy of a great mind; he had in one inſtance refuſed to ſee the proofs of a conſpiracy formed againſt him, and it was hoped he might have followed the track of his illuſtrious father. A fatal incident decided his fluctuating character. An aſſaſſin was employed to deſtroy him; in making the attempt he exclaimed "the ſenate ſends you this." The deed was prevented, and Commodus from that hour encouraged a deep-rooted hatred for the whole body of ſenators. Spies and informers increaſed his ſuſpicions and excited his jealouſy of power in any other hands than his own. Accuſation was regarded as proof, and the mockery of a pretended trial led only to certain condemnation. The execution of any conſiderable ſenator was ever attended with the death of all thoſe who ſhould attempt to revenge, or publicly dare to lament his fate, and when Commodus had taſted of human blood, he became incapable of pity or remorſe. His miniſters were one after another the victims of his fears or of his cruelty. Perennis was condemned to die for a charge of aſpiring to the empire, and after his death the conduct of Commodus aſſumed the appearance of virtue. He repealed the moſt odious of his miniſter's acts, loaded his memory with public execrations, and aſcribed to his pernicious counſels, all the errors of inexperienced youth. But his ſeeming repentance laſted only a ſhort month, and then every ſentiment of humanity appeared to be obliterated from his breaſt. He abandoned the reins of government to the moſt unworthy, and he valued nothing in ſovereign power, except the unbounded licence of indulging his ſenſual appetites. His hours were ſpent in a ſeraglio of beautiful women and boys, ſelected from all ranks of the people, and from every province of the empire. The intervals of luſt were filled up with the baſeſt amuſements. The ſervile crowd, whoſe fortune depended on their monarch's vices, applauded theſe vile purſuits. Having by long practice attained great ſkill in the uſe of the bow, he exhibited his talents before the people, and animals of the rareſt ſpecies were collected from the remoteſt part of his dominions in order to ſerve as marks for the ſceptered archer. The perfidious voice of flattery reminded him that by exploits of the ſame nature, the Grecian Hercules had acquired a place among the gods, and an immortal memory among men. He accordingly aſſumed the title and inſignia of Hercules; in this character he aſſembled all the helpleſs and diſtreſſed of the city, and cauſing them to be wrapped up in fantaſtical habits, like dragons and monſters, and armed with ſponges inſtead of ſtones, he ruſhed upon them with his club and laid them all dead at his feet. He exhibited himſelf more than 700 times in the character of a gladiator, and in all his combats he was victorious, but his amuſements in this way were frequently fatal to his antagoniſts. It would take more of our work than can be allotted to this article to deſcribe all the cruelties and acts of ſavage barbarity which diſgraced the reign of Commodus. At length his deteſtable career came to its merited end. Oppoſition to his bloody deſigns was given by ſome of his boſom counſellors, among whom was Marcia, his favourite concubine. He reſolved to put them to death, and entered their names in a long liſt deſtined to the ſame fate. Marcia diſcovered his intentions, and apprized her friends of their common danger. They reſolved to anticipate the blow, and Marcia mixing ſome poiſon in wine, preſented it to him as he came from the bath. He ſoon fell aſleep, but the doſe not being ſufficiently ſtrong, he awoke; while, however, he was labouring under the effects of the poiſon, a robuſt youth, by profeſſion a wreſtler, entered his chamber, and ſtrangled him without reſiſtance. The body was ſecretly conveyed out of the palace, before a ſuſpicion was entertained either in the city or the court of the emperor's death. Such was the fate of Commodus, and "ſo eaſy," ſays the hiſtorian, "was it to deſtroy a tyrant, who, by the artificial powers of government, had oppreſſed, during thirteen years, ſo many millions of ſubjects, each of whom was equal to their maſter in perſonal ſtrength and perſonal abilities." Gibbon.

COMMOIGNE, in *Law*, a word ſignifying a fellow-monk, that lives in the ſame convent. 3 Inſt. 15.

COMMON, in *Agriculture*, an open piece of ground, made uſe of equally by different perſons who occupy lands in the pariſh to which it belongs or in which it lies.

It is remarked by Mr. Marſhall in his "Treatiſe on Landed Property," in regard to the origin of commonable lands, "that, a very few centuries ago, nearly the whole of the lands of England lay in an open, and more or leſs in a commonable ſtate. Each pariſh, or townſhip, (at leaſt in the more central and northern diſtricts) compriſed different deſcriptions of lands; having been ſubjected, during ſucceſſive ages, to ſpecified modes of occupancy, under ancient and ſtrict regulations, which time has converted into law. Theſe parochial arrangements, however, varied ſomewhat in different diſtricts; but, in the more central and greater part of the kingdom, not widely. Under this ingenious mode of organization, each *pariſh* or *townſhip* was, he ſays, conſidered as *one common farm*, though the tenantry were numerous. Round the village in which the tenants reſided lay a few ſmall incloſures or *graſs yards* for rearing calves, and as baiting and nurſery grounds for other farm-ſtock. This was the common farmſtead or *homeſtall*, which was generally placed as near the centre of the more culturable lands of the pariſh or townſhip as water and ſhelter would permit." And that "round the homeſtall lay a ſuit of *arable fields*, including the deepeſt and ſoundeſt of the lower grounds, ſituated out of waters' way, for raiſing corn and pulſe: as well as to produce fodder and litter for cattle and horſes in the winter ſeaſon." While in the loweſt ſituation, as in the water-formed baſe of a rivered valley, or in ſwampy dips, ſhooting up among the arable lands, lay an extent of *meadow grounds* or *ings*, to afford a ſupply of hay for cows and working ſtock, in the winter and ſpring months.

That on the out-ſkirts of the arable lands, where the ſoil is adapted to the paſturage of cattle, or on the ſpringy ſlope of hills, leſs adapted to cultivation, or in the fenny leaſes of vallies, which were tunnel or gravelly water-formed lands, which were too dry to produce an annual ſupply of hay with ſufficient certainty, one or more *ſtinted paſtures*, or hams, were laid out, for milking cows, working cattle, or other ſtock which requires ſuperior paſturage, in ſummer.

While the bleakeſt, worſt-ſoiled, and moſt diſtant lands of the townſhip were left in their native wild ſtate, for *timber* and *fuel*, and for a *common paſture*, or ſuit of paſtures, for the more ordinary ſtock of the townſhip, whether horſes, rearing cattle, ſheep or ſwine, without any other ſtint, or reſtriction, than what the arable and meadow lands indirectly gave; every joint tenant, or occupier of the townſhip, having the nominal privilege of keeping as much live ſtock on theſe commons, in ſummer, as the appropriated lands he occupied would maintain, in winter.

Further, that the appropriated lands of each townſhip were laid out with equal good ſenſe and propriety. That each occupier might have his proportionate ſhare of lands of different qualities, and lying in different ſituations, the arable lands more particularly were divided into numerous parcels, of ſizes, doubtleſs, according to the ſize of the given townſhip, and the number and rank of the occupiers.

And that the whole might be ſubjected to the ſame plan of management, and be conducted as one common farm, the arable lands were moreover divided into compartments, or "fields," of nearly equal ſize, and generally three in number, to receive, in conſtant rotation, the triennial ſucceſſion of fallow, wheat (or rye), and ſpring crops, (as barley, oats, beans, and peas), thus adopting and promoting a ſyſtem of huſbandry, which, howſoever improper it is become in theſe more enlightened days, was well adapted to the ſtate of ignorance and vaſſalage of feudal times, when each pariſh or townſhip had its ſole proprietor; the occupiers being at once his tenants and his ſoldiers, or meaner vaſſals. The lands were in courſe liable to be more or leſs deſerted by their occupiers, and left to the feebleneſs of the young, the aged, and the weaker ſex. But the whole townſhip being, in this manner, thrown into one ſyſtem, the care and management of the live ſtock at leaſt would be eaſier and better than they would have been under any other arrangement. And at all times, the manager of the eſtate was better enabled to detect bad huſbandry, and enforce that which was profitable to the tenants and the eſtate, by having the whole ſpread under the eye at once, than he would have been had the lands been diſtributed in detached incloſed farmlets, beſides avoiding the expence of incloſure. And another advantage, he thinks, aroſe from this more ſocial arrangement: in barbarous times the tenants, by being concentrated in villages, were not only beſt ſituated to defend each other from predatory attacks,

tacks, but were called out by their lord with greater readineſs in caſes of emergency.

But it is remarked, that beſide the organized townſhips which were inhabited and cultivated in the manner deſcribed, there were, and are to the preſent day, in different parts of England, extenſive tracts of lands, ſome of them of a valuable quality, which lie nearly in a ſtate of wild nature!—Theſe uninhabited tracts are ſtyled *foreſts*, and heretofore many or moſt of them have been attached to the crown; and ſome of them are ſtill under royal patronage. Whether they were originally ſet out for amuſement merely, or whether the timber which ſtood on them was of peculiar value, or whether, at the time of laying out townſhips, thoſe tracts were impenetrable woods. inhabited by wild beaſts, and when theſe were deſtroyed, or ſufficiently overcome to render them objects of diverſion, wete taken under the protection of the crown, is not perhaps well aſcertained. But let the original intention have been either of theſe, it no longer exiſts. The timber in moſt caſes has fallen a ſacrifice to age and neglect, and the *game* is no longer an object of regal paſtime. But whether or not the foreſts (now ſo called) originated in wild woodlands, occupied by ferocious animals at the time of laying out townſhips, there were doubtleſs tracks of that deſcription in different parts of the kingdom, and which now bear no marks of the common field ſyſtem; but which appear evidently to have been incloſed from a ſtate of woodland or common paſture; though it is poſſible they may have been nominally attached to neighbouring pariſhes. Of this deſcription principally are the wealds of Kent and Suſſex, and many other old incloſed lands in different parts of the kingdom, whoſe fields or incloſures are of irregular ſhapes, and their fences crooked. And it is obſervable, that theſe woodland diſtricts, as the foreſt lands, are divided into manors, which have not an intimate connection, or correſpondence with pariſhes or townſhips; a further evidence that they were in a wild ſtate, when the feudal organization took place.

It is ſtated by the author of "Modern Agriculture," that "on all the open field pariſhes, where the ſame arrangement continues as was at firſt eſtabliſhed, there is a conſiderable extent of common field allotted for the paſturage of the live ſtock belonging to the inhabitants. Theſe generally conſiſt of ſuch lands as are leſs fit for the plough, or more diſtant from the town or village. The pariſh commons are for the moſt part divided into three fields; one for the paſturage of the horſes, another for the neat cattle, and the third for the ſheep. Theſe horſes are generally tended by one of the farmer's ſervants. The whole of the ſheep belonging to the pariſh are put under the charge of a common ſhepherd, who is hired at the general expence; and the cows and young cattle are taken care of nearly in a ſimilar manner. Where the inhabitants of ſeveral adjoining pariſhes poſſeſs rights of common paſturage on an extenſive common, as is frequently the caſe, particularly in the counties of Middleſex, Surry, Northampton, and other diſtricts in the middle and ſouthern parts of the kingdom, all the horſes, cattle, ſheep, hogs, &c. which are ſent to the commons, are committed to the care of one or more perſons appointed for the purpoſe. In ſome caſes the right is limited; or, as it is called, *ſtinted*. When that is the caſe, ſuch a number of cattle only, as the ſtraw and hay growing on the farms will maintain in winter, is permitted to paſture theſe commons in ſummer. And therefore each farmer is, by particular laws, prevented from ſending above a certain number, which is regulated, partly by the extent of his farm, and in ſome caſes by the title on which he claims a right of commonage in the particular inſtance.

But where the common is unſtinted; or in other words, where the farmers poſſeſs right of paſturing any number and ſpecies of live ſtock which they chooſe to ſend, and without reſtraint of any kind, the value of ſuch right is conſidered by many farmers ſo inconſiderable as not to be worthy of their attention. Such farmers as poſſeſs improved breeds of horſes, cattle, and ſheep, ſeldom, indeed, if ever, ſend any of them to be paſtured on the commons, whether ſtinted or unſtinted. They generally diſpoſe of their right, for a trifle, to ſome neighbouring farmers or dealers, who have no objection, in the view of profit, of running the riſk of their cattle meeting with accidents, or being infected with diſeaſe, as muſt naturally be expected to happen on theſe extenſive commons, where ſo many cattle are promiſcuouſly collected together.

It has been remarked by a late able writer, that "the commons in Middleſex, as in moſt other places, are three fourths of them covered with heath and furze, from which a little of the worſt ſort of firing is obtained by the poor. The trifling quantity of food which cattle conſume from theſe ſhrubs, does not, and indeed cannot, improve them, as it is barely ſufficient to keep them from ſtarving. Much of the remainder is occupied by roads, gravel pits, and ponds, yielding nothing. After the moſt mature conſideration, he is inclined to think, that about 5,500 acres of the commons in the above county are employed in the production of graſs for the feeding of cattle, affording indeed but a miſerable paſture, as the greater part is under water during winter; and, from being poached and trodden down by cattle while wet, is rendered hard, lumpy, full of holes, and partakes of the ſterility of mortar during ſummer. The graſſes are moſtly of the dwarf kind, and of ſcanty produce, with a large proportion of the carnation and other graſſes which are known to be rather more dangerous than nouriſhing; ſo much ſo, as to induce ſome of the moſt obſerving farmers in various parts of the kingdom, poſſeſſing extenſive common rights, after a fair trial to refrain altogether from turning their cattle on ſuch commons.

On ſuch authority it may well, he ſays, be queſtioned, whether commons are of any more uſe to the community than they would be were they conſigned to the bottom of the deep. But without attempting the ſolution of ſuch a queſtion at preſent, he may be allowed to obſerve, that the value of commons, conſidered ſolely as to their power of increaſing animal food, and as totally unconnected with the adjoining incloſures, is extremely ſmall indeed. But when conſidered as affording an opportunity to the neighbouring farmer to turn his ſtock out, at certain ſeaſons of the year, they become an object of ſome importance. For in the ſpring quarter of the year, by receiving the ſtock during theſe months, the growth of hay is encouraged, they anſwer the purpoſe of paſture, and the farmer is thereby enabled to mow all his graſs land: which muſt ſenſibly increaſe the quantity of hay to be ſent to market; as at Finchley and Harrowweald in this county; or being applied during the winter months to the ſupport of a greater quantity of live-ſtock in places more diſtant from a good hay-market; and in others, for the purpoſe of folding on the arable land."

It is further ſtated, that "on eſtimating the value of the commons in the ſame county, including every advantage that can be derived from them in paſturage, locality of ſituation, and the barbarous cuſtom of turbary, it appears, he ſays, that they do not produce to the community, in their preſent ſtate, more than four ſhillings per acre! On the other hand, they are, in many inſtances, of real injury to the public, by holding out a lure to the poor man for procuring the means of materials wherewith to build his cottage, and ground to erect it upon; together with firing, and the run of his poultry and pigs for nothing. This is of courſe temptation ſufficient to induce a great number of poor perſons to ſettle upon the borders of ſuch commons, But the miſchief does not, he ſays, end here: for having gained theſe trifling advantages, through the neglect or connivance of the lord of the manor, it unfortunately gives their minds an improper bias, and inculcates a deſire to live from that time forward without labour, or at leaſt with as little as poſſible. The animals kept by this deſcription of perſons, it is ſoon diſcovered by their owners, are not likely to afford them much revenue, without better feed than the ſcanty herbage of a common. Hence they are tempted to pilfer corn, &c. towards their ſupport: and, as they are ſtill dependent on ſuch a deceptious ſupply, to anſwer the demands of their conſumption, they are in ſome meaſure conſtrained to reſort to various diſhoneſt means, ſo as to make up the deficiency.

And there is another very ſerious evil which the public ſuffers from theſe commons, the ſame writer obſerves, which is, "that they are the conſtant rendezvous of gipſies, ſtrollers, and other looſe perſons, living under tents, which they carry with them from place to place according to their conveniency. Moſt of theſe perſons have aſſes, many of them horſes, nay, ſome of them have even covered carts, which anſwer the double purpoſe of a caravan for concealing and carrying off the property they have ſtolen, and alſo of a houſe for ſleeping in at night. They uſually ſtay a week or two at a place; and the cattle which they keep ſerve to tranſport their few articles of furniture from one common to another. Theſe, during the ſtay of their owners, are turned adrift to procure what food they can find in the neighbourhood of their tents, and the deficiency is made up from the adjacent hay-ſtacks, barns, and granaries. They are known, he ſays, never to buy any hay or corn, and yet their cattle are ſupplied with theſe articles of good quality. The women and children beg and pilfer, and the men commit greater acts of diſhoneſty. In ſhort, ſays he, the commons of this county are well known to be the conſtant reſort of footpads and highwaymen, and are literally and proverbially a public nuiſance. And that they are ſo in the more diſtant counties is evident, from the Glouceſter and Hereford reports of the ſtate of agriculture. There are alſo many additional injuries which commons render to ſociety, of other kinds to thoſe which have been noticed above. But that the commons of Middleſex, ſays he, are capable of being improved, ſo as to produce large crops of all the vegetables uſually cultivated, and to rear and ſupport a very highly improved breed of cattle, there can be no ſort of doubt. Indeed it is truly lamentable to ſee, in every part of theſe kingdoms, ſuch extenſive tracts of land lying waſte or uncultivated; producing no revenue to the owners of ſuch property, and extremely doubtful if of any, the ſmalleſt benefit to the community. But it is particularly diſgraceful to this, the firſt and principal county, which, ſo far from raiſing a ſufficient ſupply of bread for its inhabitants, is under the neceſſity of importing corn from every quarter of the world (Europe, Aſia, Africa, and America,) while, at the ſame time, it has ſo many acres of good land lying waſte, and locked up from the operation of the plough. By the ſingle means of incloſure an abundant quantity of corn might be produced, and 150,000 *l.* a year added to the wealth of the county, which is now abſolutely loſt to ſociety, with as careleſs an indifference as if the proprietors of the ſoil were afraid of becoming too rich; or, as if like the dog in the manger they would not permit the community to ſhare in a bleſſing of which they themſelves are not inclined to partake.

The benefits and advantages that would be derived from a general incloſure of commons, are, he thinks, ſo numerous, as far to exceed his powers of deſcription or computation. The opportunity it would afford of ſeparating dry ground from wet, of well draining the latter, and liming the rotten parts, is of infinite conſequence: as ſuch an arrangement would, with the aid of intelligent breeders, be the means of raiſing a breed of ſheep and neat cattle far ſuperior to the preſent race of wretched half-ſtarved animals now ſeen in ſuch ſituations. It would have the effect of ſupporting a more numerous ſtock upon the ſame quantity of food by reſtraining the cattle and ſheep within due bounds. Their reſtleſs and rambling diſpoſition not only treads the graſs off the ground, but alſo takes the fleſh off their bones. This renders the attendance of a ſhepherd neceſſary, and requires likewiſe that they may be driven to and from the fold. Further, the live-ſtock would by this means be rendered many hundreds per cent. more valuable to individuals and the community than it has hitherto been, or can poſſibly be, without incloſure; and, what is of the laſt, the greateſt importance, it would tend to preſerve ſuch improved breeds from that deſtructive malady, (the rot) which makes ſuch terrible havoc among our flocks. Add to this, that the markets would be more plentifully ſupplied with beef and mutton, and the price of theſe articles conſiderably reduced.

It does not, he ſays, appear neceſſary to ſtate with preciſion (nor indeed is it capable of being ſo ſtated) what would be the encreaſe or value of the commons of this country on their being incloſed and well and properly cultivated. It may, however, with ſafety be ſtated at upwards of 15 times their preſent value to the proprietors, and 40 times their preſent value to the public. But increaſing the rental of ſuch land to 15, or perhaps 20 times, its preſent amount, is by no means the greateſt advantage that may be expected to reſult from an incloſure of commons. The general ſalubrity and healthineſs of the country would neceſſarily be improved, while induſtry would be largely encreaſed among the moſt uſeful claſſes of ſociety, beggary and robbery much leſſened, and the general ſtock of corn and cattle almoſt inconceivably augmented. And whereever incloſures are made with due attention to the intereſt of the poor (as they ought always to be), they will be found to ameliorate their condition, as much as they increaſe the property and the comforts of the rich."

It is further obſerved, that "the commons of this kingdom being, with very few exceptions, without ridges, furrows, or drains, have not the means of diſcharging that ſuperfluous water from the ſurface of them, which is well known to be of great detriment to vegetation in general.

Many commons in low ſituations, and where the ſoil happens to be of a retentive quality, hold water like a ſponge, which being always ſtagnant, as well as exceſſive in quality, renders the ſoil of ſuch commons much too wet for the paſturage of ſheep, and is, no doubt, the cauſe of many of the diſorders which that animal is ſubject to, particularly that fatal malady, the rot. From the ſame cauſes, alſo, the neighbourhood of moſt commons muſt be particularly unfriendly to the health and longevity of man. Only let us, ſays he, reverſe the ſcene, and for a moment ſuppoſe theſe commons to be incloſed, the neceſſary ditches and drains ſunk, and the land brought into tillage, and we ſhall ſee all the ſuperabundant moiſture got rid of; and the water, being kept in conſtant motion, by trickling down the ſides of the ridges into the furrows, and from thence into the ditches and rivulets, will be found to fertilize the very ſoil which in its preſent ſtagnant ſtate it ſerves to injure; while, by leaving the land dry, it will be rendered more healthy both for men and cattle. The effects of ſuch a meaſure would ſoon ſhew themſelves in many diſtricts of this iſland, which, at preſent, are very unpropitious to the health of man, in the much greater longevity of the inhabitants. It may alſo be further noticed, he ſays, that commons are entirely defective in the great article of labour; but no ſooner does an incloſure take place, than the ſcene is agreeably changed from a dreary waſte, to the more pleaſing one of the ſame ſpot, appearing all animation, activity, and buſtle. Every man, capable of performing ſuch operations, is furniſhed with plenty of employment, in ſinking ditches and drains, in making banks and hedges, and in planting quicks and trees. Nor are the wheelwright, carpenter, ſmith, and other rural artificers, under the neceſſity of being idle ſpectators of the ſcene, ſince abundance of work will be found for them, in the creation of farm houſes, and the neceſſary appendages thereto; and in the forming and making of roads, bridges, gates, ſtiles, implements of huſbandry, &c. Even after a few years, when this kind of temporary exertion is over, by the whole being brought into a regular ſyſtem of huſbandry, it will ſtill continue to provide both food and employment for a very increaſed population.

“ It is highly probable, he thinks, that if the legiſlature ſhould paſs an act for the general incloſure of waſte land, it would increaſe the quantity of rural labour ſo much as to advance its price conſiderably, and thereby have the good effect of drawing a vaſt number of hands out of the unwholeſome confinement of manufactories; where, in addition to the life-ſhortening effects of ſuch confinement, the morals of the people are expoſed to certain contamination.”

With reſpect to the effect produced by incloſures on the population of the country, it may be obſerved, that the incloſing of 1000 acres in any one pariſh would probably require 100 different labourers, many of whom would undoubtedly be drawn from ſuch of the adjoining pariſhes as had leſs work than workmen. Thus it muſt follow, that the neighbouring towns and villages would diminiſh, juſt as much as the pariſh in which the incloſure is going forward, would increaſe its numbers; yet the amount of the community will evidently be the ſame. But although the incloſing of waſte land certainly does not immediately either increaſe or leſſen population, as ſome writers ſeem to have ſuppoſed, yet, that incloſures ultimately affect population, (and that as to its increaſe,) inſomuch as the diſtrict is thereby made more conducive to health, is, he ſays, ſufficiently evident. Every thing that has a tendency to make a nation more healthy and productive, muſt, of neceſſity, operate as a ſtimulus to population. The certainty of a man's being able, with eaſe and comfort, to provide for himſelf and family, by the increaſe of rural labour, is at once an inducement to marriage, and a conſequent increaſe of population.

The inhabitants wholly ſupported by agriculture in England and Wales, appear, the ſame writer ſays, to be nearly, or perhaps quite, ſix millions, (while it ſupplies proviſions for near two millions more,) or one to every ſix acres and a half of cultivated ſoil. The eſtimation is made in this manner.

Estimate.

Cultivators of farms, ſix perſons to every 100 acres, is - - - - - - -	2,340,000
Ditto of gardens, hop-grounds, nurſeries, &c.	300,000
	Brought over 2,640,000
Smiths, wheel-wrights, bricklayers, maſons, carpenters, painters, plumbers, glaziers, various manufacturers of furniture, woollen cloth, and making it up, linen, and making it up, leather, and making it into ſhoes, boots, &c. horſe, harneſs, and ſaddlery; as many of each of this deſcription of perſons, as are wholly employed by the cultivators of the ſoil; men, women, and children, about ſeven perſons to each farm, of 100 acres, is - - - - - - -	2,800,000
The like of millers, bakers, malſters, brewers, diſtillers, ſtarch-makers, dealers in corn, and perſons employed in the commerce of corn -	500,000
The landlords of farms - - - - -	40,000
Perſons ſupported by taxes on the produce of land - - - - - - - - -	120,000
	6,100,000

Not but that the extremes vary much, as there are ſome few grazing farms, with only one ſoul to fifty, and arable farms that are peopled in the proportion of one perſon to three acres of land. In point of produce, the commons, in their preſent ſtate, apparently, though, he thinks, not really afford entire ſupport to human beings, in the proportion of one to an hundred acres. But by being incloſed, and brought into the preſent ordinary cultivation of the country, every ſix acres and a half might do the ſame.

Should agriculture experience a rapid advance towards perfection, as there is reaſon to imagine it will, both from the exertions of the board, and of intelligent individuals, every three or four acres, would, in a few years, be capable of ſupporting its inhabitant; and, as from its nature, it might certainly be carried on from one degree of perfection to another; it may even arrive at ſuch a pitch of excellence, as that every acre of land ſhall ſupport its man.”

It has long ſince been well obſerved by Dr. Anderſon, that while land is in the condition of common, man is debarred from ever being able to ameliorate the ſoil, and thus to augment its product to the ſtate; but that he is not prevented ſo effectually from deteriorating it. While, in the ſtate of a common, the ſurface of the ground may be broken by him in ſuch a way, as not to recover for ages a ſward equal to that which was originally upon it. It may be caſt up and ſunk into pits; it may be converted into wet and rotten marſhes, by caſual obſtructions being thrown in the way of the water, which no one finds it his intereſt to remove; it may, in ſhort, while a common, be abuſed in a thouſand ways, by reaſon of the obſtinacy, indolence, or caprice of individuals, but it never can be benefited by the induſtry of man; and not only may this be done, but theſe things actually are done, in innumerable inſtances; ſo that to a perſon who contemplates the loſs that the nation muſt ſuſtain by theſe deplorable abuſes, nothing can afford a more melancholy train of reflections, than that which the frequent recurrence of thoſe diſguſting commons ſuggeſts to his mind, as he travels over the otherwiſe delightful country of England. When he ſtops to inquire more minutely into the effects of this kind of property upon the morals and domeſtic economy of the individuals who claim a right to theſe commons, he only finds additional cauſes, he ſays, of regret. He frequently diſcovers that the quiet and induſtrious cultivator, having a right upon a common, is obliged to abandon

don that right, becauſe of the harraſſments to which he is ſubjected from turbulent and aſſuming neighbours, who have obtained a ſmall footing there, with a predetermined reſolution, perhaps, to encroach much farther than their rights would authoriſe; becauſe they know that towards the reſtraining of theſe exceſſes, no obvious and eaſy means occur. Thus does the peaceable man often find it better to relinquiſh his right almoſt entirely, than be ſubjected to the perpetual contention that would occur in defending it. Such an inquirer frequently finds, that in conſequence of this, the ſmall flocks of the poor cottager, who cannot afford to look after them continually himſelf, are ſo tormented by being chaſed from place to place by theſe marauders, that inſtead of a relief to the poor cottager, theſe flocks prove only a torment to him; his family becomes, in conſequence of this, a burthen on the pariſh, which is obliged to ſupport them; he finds, that among thoſe who are bred up in theſe ſituations, there are many young men who delight more in active plunder, than in ſober induſtry; and who, tempted by the high prices that luxurious inhabitants of towns offer for game, become poachers, and from ſuch powerful confederations of determined profligates for their mutual protection, that no one, leſs determined than themſelves, will dare to interfere with them; which enables them to carry on their depredations with impunity. He further obſerves, that the money theſe young men thus acquire, is uſually ſquandered in drinking and riotous exceſſes; the young women are contaminated by their converſation, corrupted by their exceſſes, and debauched; the laſt evil attending which courſes, is a great number of illegitimate children, and an extravagant poor rate. But who, ſays he, can eſtimate the detriment that a nation ſuſtains, when the morals of the country inhabitants of it become corrupted? It is like, ſays he, tainting the ſprings of water with poiſon, which, inſtead of promoting health and vigour, as they naturally ought to have done, produce one univerſal maſs of infectious diſeaſe. It is common, he adds, to read in the Hiſtory of Britain, that the rot became at times ſo prevalent in England, as to carry off many millions of ſheep at once; and theſe diſeaſes were regarded, like the peſtilence among the human ſpecies, as a terrible viſitation of heaven for the ſins of a guilty land. There is great reaſon to believe that theſe frequent mortalities among the flocks were entirely occaſioned by the numerous commons, which were in thoſe times much more extenſive than at preſent; for it is ſtill known, that in neglected ſpots, where water is allowed to ſtagnate and generate marſhes, as is often the caſe with commons when the ſeaſon proves wet, the ſheep paſtured upon them are, to this day, ſo much ſubjected to the rot, as to induce many perſons, as has been obſerved, rather to give up their right, than to allow their flocks to enter upon theſe unhealthy paſtures. Conſidered under every poſſible point of view, then, ſays he, it appears to be undeniable, that the prevalence of commons is a great national grievance, which ought, if poſſible, to be removed; and that the Board of Agriculture cannot be more beneficially employed, than by granting all the aid that their wiſdom can deviſe, for removing theſe bars that at preſent tend to prevent the equitable diviſion of this kind of property.

It is evident from every one of the agricultural ſurveys which have been yet made, he ſays, that in every county in England and Wales, there are extenſive tracts of land of this deſcription (for commons and waſtes may be conſidered as nearly ſynonymous terms, although it be a truth that many of theſe commons conſiſt of land naturally as good as any in the kingdom). Of the extent of theſe lands, were it neceſſary, a tolerably accurate knowledge, he thinks, might be obtained; but as to the amount of improvement, it is impoſſible for any perſon to form at preſent an idea of it, ſhould the proſperity of this country be permitted to go forward for a conſiderable length of time in that accelerating ratio into which it would naturally fall, if the general tranquillity of the nation were preſerved, and the obſtructions which have hitherto repreſſed exertions in agriculture removed. It is enough here to ſay, he thinks, that it would be an object of immenſe magnitude. He has had occaſion to obſerve, that in ſome favourable ſituations, it is well known that land, in the courſe of a very few years, has been made a thouſand times at leaſt more productive than in its original ſtate. Many commons are at preſent lying waſte in ſituations equally favourable as theſe; and many other ſituations may become equally favourable by an extenſion of thoſe modes of facilitating intercourſe, which are now in contemplation, and are only prevented from being carried into effect by barriers that judicious laws may eaſily remove. See Waste Land.

In regard to the appropriation of commonable lands, it has been obſerved by Mr. Marſhall, that the ſpecies of unappropriated lands in this country are, at preſent,

1ſt. "Foreſt lands, and other extenſive waſtes, on which ſeveral manors, or adjacent townſhips, have a right of common paſturage.

2d. "Commonable lands of diſtinct townſhips, or manors, whoſe appropriated lands are wholly incloſed, and in a ſtate of mixed cultivation.

3d. "Commonable lands of townſhips, whoſe arable fields, &c. are partially incloſed;" and

4th. "Commonable lands of townſhips, whoſe arable fields remain wholly open."

And in reſpect to the principles on which the appropriation of ſuch lands requires to be conducted, it may be obſerved, that as, by an eſtabliſhed principle of the general law or conſtitution of the country, immemorial cuſtom eſtabliſhes right, neither the original rights and regulations, reſpecting ſuch lands, nor the changes which may have taken place during a ſucceſſion of centuries, from the origin of foreſts and townſhips, to the lateſt periods of time, are objects of inveſtigation or inquiry; but many acquired rights which exiſt in any certain caſe at the time of appropriation, and which would continue to exiſt were it not to take place. "The poſſeſſor of a cottage," ſays the ſame writer, "which has enjoyed, time immemorial and without interruption, the liberty of paſturage, though ſuch cottage were originally an encroachment of a *freebooter* or an *outlaw*, has indiſputably as legal a claim to a proportionate ſhare of the commonable lands, as the poſſeſſor of the demeſne lands of the manor has (merely as ſuch), although they may have deſcended from father to ſon from the time of their ſeverality. For it is evidently on the eſtimated values of the reſpective *rights which exiſt*, and which can be rightfully exerciſed in *time to come*, and on theſe alone, that a juſt and equitable diſtribution can be effected."

It is, however, ſtated, that before the diſtribution of commonable lands among the owners of common paſturage can take place, the more *abſtract rights* which belong to commons require to be eſtimated, and the juſt claims of their poſſeſſors to be ſatisfied. Theſe are, he ſays, principally manorial rights, and the rights of tithes.

The manorial claims are to be regulated by the particular advantages which the lord of a given manor enjoys, and which he will continue to enjoy, while the commons remain open and unappropriated; whether they ariſe from mines, quarries, water, timber, alien tenants, fuel, eſtover, pannage, or game? And that "his claim, as guardian of the ſoil, as productive of *paſturage only*, is in moſt caſes only honorary; he cannot as ſuch (unleſs through ancient cuſtom) profit by the *herbage* or the *browſe* that the ſoil produces." But that " the claim of the lord of the manor, in right of the ſoil on which *thriving timber* is ſtanding, is ſubſtantial. For out of this, he has, in effect, a real yearly income, equal to the annually increaſing value of the timber: a ſpecies of advantage which, if the commons remain open and unappropriated, he will in courſe continue to enjoy, ſo long as the timber continues to increaſe in its value. His claim, therefore, in this reſpect, depends on the quantity of timber, and its ſtate of growth taken jointly. Young thriving timber not only affords an annual increaſe of value at preſent, but will continue its benefits for many years to come, if it be ſuffered to remain undiſturbed on the ſoil which ſupports it, during the eſtimated period of its future increaſe; whereas, dotards, and ſtinted trees which afford no increaſe of value, do not entitle their owner to any ſhare of the ſoil they ſtand upon. The trees themſelves, or their intrinſic value, are all the lord of the manor can have a right to claim."

And further, in like manner, the claims of the crown, or of hereditary rangers (if any), on the foreſt lands, ought, he conceives, to be ſatisfied.

But the claims of *tithe owners*, aggregately conſidered, are more complex and obſcure. In a caſe where the great and ſmall tithes are united, where the tithe of wool and lamb, and that of grain, roots, and herbage, belong to the ſame owner, and where no modus exiſts, it may ſeem to be reaſonable that he ſhould have the option of receiving land of equal value to the exiſting value of the whole of the tithes, or of taking the chance of their value, in the ſtate of cultivation. But ſeeing the evil tendency of corn tithes, and the impropriety of laying on ſo harmful a burthen, as they are now become, upon lands that have never borne it, there can be little riſk in ſaying that it would be at leaſt politic in parliament to prevent it. Beſide, it ſtands part of the ſtatute law, he believes, that the lands which have never been under tillage, ſhall not pay tithes during the firſt ſeven years of their cultivation; during which time, the incumbent's income might, by leaving the tithe to take its courſe, be materially abridged, and his circumſtances thereby be rendered diſtreſſing.

It is therefore concluded, that, on the whole, it appears to be proper in this caſe, that the law ſhould inſtruct commiſſioners to ſet out lands equal to the exiſting value of the tithes at the time of appropriation; and, where much corn land (land fit for corn) ſhall be appropriated, to ſet out a farther quantity, equal to the reverſion of the extra value of the tithes to ariſe from ſuch corn lands, ſeven years after the appropriation ſhall have taken place, above the value of the tithes that exiſt, provided any ſuch extra value ſhall appear by the eſtimates.

And further " in caſes in which the tithe of lamb and wool, and the tithe of corn, &c. belong to ſeparate owners, the line of rectitude and ſtrict juſtice to all parties, appears, he ſays, to be ſtill more difficult to draw. The former is clearly entitled to land, or a money payment equal to his loſs of tithe; but the right of the other is leſs obvious. To cut him off entirely from any ſhare of the lands, and likewiſe from any ſhare of tithes to ariſe from them after they ſhall be appropriated, may ſeem unjuſt; he may be a lay rector, and may have lately purchaſed the tithes, or a clerical rector who has recently bought the advowſon under the expectation of an *incloſure*. On the other hand, it appears to be hard that the proprietors of the pariſh ſhould firſt give up land for the tithe of wool and lamb which will no longer exiſt, and then be liable to a corn tithe on the ſame lands, after they ſhall have beſtowed on them great expence in clearing and cultivation. Indeed the injuſtice of ſuch a meaſure is evident. A middle way, therefore, he thinks, requires to be ſought; and it will be difficult, perhaps, to find one which has more juſtice in it than that which is propoſed for the firſt caſe."

It may, however, ſays he, be urged that, admitting the foregoing regulation to be the true ground on which a remuneration in lieu of tithes of commonable lands ought to be eſtimated, the difficulties of cultivation would in ſome caſes be great, and might be the cauſe of diſpute and delay in the general work of appropriation; and a more practical method, though leſs reconcileable to theory, preſents itſelf. Thus, let a certain proportion in value, of the lands to be appropriated as one, be aſſigned in lieu of the whole of the tithes of the townſhip or manor, ſuppoſing the whole be payable in kind; and if there are more than one tithe owner in the manor or townſhip, let the commiſſioners divide ſuch aggregate allotment among the ſeveral owners and claimants, as the rector, the vicar, &c.; and the owners of land, &c. who pay tithe by ancient modus not in kind: ſuch owners being entitled to a ſhare of the ſame as the tithe owners, in proportion to the advantage they receive, by ſuch ancient privilege.

And if any other abſtract claim on the lands to be appropriated be fairly made out, or any alien right, as that of a non-pariſhioner, or extra manorial occupier who has acquired by ancient grant, or by preſcription, the privilege of depaſturing them, be fully proved, its value requires to be accurately eſtimated, and land to be aſſigned in lieu of it."

When this has been done, the remainder of the *unſtinted commons* of a given townſhip or manor belongs to the owners of its common right lands and houſes; but in what proportion may be difficult to determine with mathematical preciſion. Nevertheleſs, by adhering ſtrictly to the general principle, on which alone he conceives an equitable appropriation can be conducted, *viz.* that of determining each man's ſhare by the benefit which he has a right to receive at the time of appropriation, and which he might continue to receive, were it not to take place, truth and juſtice may be ſufficiently near approached.

He conſiders that one of the firſt ſteps towards an equitable diſtribution of unſtinted commons, is to aſcertain the common right houſes, and to diſtinguiſh them from thoſe which have no right of commonage, and which therefore can have no claim to any ſhare of the lands of the unſtinted commons, further than the right of the lands they ſtand upon.

By ancient, and, he believes, pretty generally received, though ſomewhat vague idea, reſpecting the rights of commonage, the occupier of every common right houſe has the privilege of depaſturing as many cattle, ſheep, or other live ſtock, on the common in ſummer (provided, it muſt be underſtood, that it is large enough to permit every occupier to exerciſe this right), as the grounds he occupies within the townſhip or manor can properly maintain in winter; and no one can exceed that proportion, for the ſurplus of the paſturage (if any) belongs to the lord of the ſoil, according to Fitzherbert and Blackſtone.

Under this regulation, the appropriated lands of a common field townſhip, which are not occupied jointly with a common right houſe, may be ſaid to be deprived, during the time they are ſo occupied, of their right of commonage. And in ſome of the private bills of incloſure, which have been ſuffered to paſs through parliament, the lands which happened to be in this ſtate of occupancy at the time of paſſing the bills, were deprived of their intereſt in the common lands, for ever: Notwithſtanding, perhaps, they had a few years preceding this accidental circumſtance, an undoubted right to their portion of them; a right which, a few weeks or a few days afterward, might have reverted to them, without the ſmalleſt ſtint, by the temporary alienation. If any of the appropriated lands of a townſhip or manor have been eſtranged from its commons, during time immemorial, have never been occupied jointly with a common right houſe, or in any way enjoyed of right the common paſturage, within memory, they may, with ſome reaſon, be ſaid to have loſt their right, and be excluded from a participation.

It is ſtated, that by this ancient, and in a degree eſſential, uſage, common right houſes have a clear right to the land of the commons, ſuperior to the ground they ſtand upon; eſpecially if they rightfully enjoy a privilege of partaking of the fuel and pannage they afford; for theſe properly belong to the houſes, not to the lands; and ſtill eſpecially if they are not conveniently ſituated for enjoying the ſeveral benefits which the commons afford in their wild ſtate. And whatever a common right houſe is worth, merely as ſuch, that is to ſay, whatever it will let or ſell for, over and above a non-common right houſe of the ſame intrinſic value, it certainly ought to participate, in the diſtribution, according to ſuch extra value.

"The true proportionate ſhares of the common right lands are to be aſcertained on the ſame principle. For although the ancient regulation reſpecting common right may continue in force while the commons remain open and unappropriated, it would be found troubleſome, or unmanageable, as a rule to their juſt appropriation. There are few, if any, commons (of common-field townſhips at leaſt) that now afford paſturage in ſummer for all the ſtock which the appropriated lands are capable of maintaining in winter; ſo that their ſeveral proportions only could be uſed: and theſe proportions may be calculated with much greater certainty and diſpatch, on the reſpective rental values of the lands, than on the more vague and troubleſome eſtimation of the quantities of ſtock they would winter, which indeed would be beſt calculated by the rental value of the land. Conſequently, in adopting this as the baſis of calculation, the ancient rule is in effect complied with.

But ſtill there is another circumſtance, he ſays, of ſome importance, which requires attention, before an equitable diſtribution can be made. For although each common right occupier may have a right to ſtock in proportion to the productiveneſs or rental value of his appropriated lands, every one could not do this with equal profit, and of courſe could not receive equal benefit. Lands ſituated on the ſide of a common, are much more beneficial in this reſpect, than lands which lie a mile or two from it, with bad roads between them. And it is the real advantage which an occupier can freely receive that is the true guide in the partition; which conſequently ought to be conducted, not on the rental value of the land, abſtractly conſidered, but on this and its ſituation with reſpect to the commonable lands, jointly. In other words, it is the rental values of the common right lands while the commons remain open, not what they will become after the commons are incloſed, which he conceives to be the proper ground-work of appropriation. And that in caſes where commonable lands are wholly attached to manors, and not common to the pariſh or townſhip in which they are ſituated, as in foreſts and woodland diſtricts, the ſelf-ſame principle of diſtribution is applicable. The remainder of the commons (after the owners of abſtract rights have been ſatisfied) belong to the common right lands and houſes, no matter whether ſuch lands and houſes belong to copyhold tenants excluſively, or to copyholders and freeholders jointly, provided the immemorial cuſtom of the manor make no diſtinction in their reſpective rights; the well eſtabliſhed cuſtoms of manors being in all caſes rules of conduct and unerring guides to commiſſioners."

With theſe, he ſuppoſes, end the great difficulties as to the principles of appropriation; the reſt he conſiders as merely technical; the works of admeaſurement, eſtimation, and calculation: operations that are familiar to profeſſional men in every diſtrict, and which require nothing but application and integrity to render them ſufficiently accurate. It is however a matter of vaſt importance to have perſons fully converſant with the ſubject as commiſſioners in all ſuch caſes.

Through the uncertainty and expence attending private acts, a great portion of theſe unſtinted common lands remain nearly as nature left them;—appearing in the preſent ſtate of civilization and ſcience, as blotches on the face of the country, eſpecially when ſeen under the threatening clouds of famine, which have now repeatedly overſpread it.

COMMON-*Field Land*, ſignifies a deſcription of land of a ſomewhat ſimilar kind to that of commons, only lying in extenſive fields. There is a large portion of this ſort of land in almoſt every county of the kingdom. It has been obſerved by Mr. Middleton, that the common arable fields in the county of Middleſex are about 20,000 acres; and in that, as well as in moſt other counties, are divided into too ſmall properties to be advantageouſly cultivated. He ſays he has known thirty landlords on a field of 200 acres; and the property of each ſo divided as to lie in ten or twenty places, containing from an acre or two downwards to fifteen perches; and in a field of 300 acres he has met with patches of arable land, containing eight perches each. In this inſtance the average ſize of all the pieces in the field was under an acre. In all caſes, he obſerves, they lie in long, narrow, winding, or worm-like ſlips. Land ſo diſtributed occaſions great loſs of time to the farmer, in removing his teams and labourers; and what is of equal importance, he can neither croſs-plough nor harrow and clean ſuch land in a workmanlike manner. And another great inconvenience attending common-field land is, the farmer cannot crop with that which beſt ſuits his ſoil, but is confined to ſow ſuch grain as muſt be cut with his neighbour's. An act to incloſe common-field land would be advantageous to the farmer, and make the eſtates compact, and of more value to the owners. Neither can he ſow any green or meliorating crops, vary the uſual impoveriſhing ſucceſſion, or even deſtroy the vermin. In ſhort, the cultivator of theſe lands finds his expences double, and his crops only half of what they might be, if the land were laid together and well fenced."

By incloſing the common-fields, ſays he, which conſiſt of a turnip and barley ſoil, both the landlord and the farmer are freed from the ſhackles of an exhauſting and obſolete rotation of crops, and placed at liberty to diſtribute for cultivation the ſoil in the moſt improved manner, keeping it clean, in better heart, raiſing ſuch roots and green crops as are in the greateſt demand at market, and only growing a crop of corn for the ſake of renewing the courſe of green and root crops. In this manner intelligent men, after incloſure, can double the produce of their land.

It is added that the invariable rotation of crops in all the common-fields is, firſt year a fallow, ſecond year wheat, third year peaſe or oats, then begin again with a fallow. This, he ſays, is the deſtructive ſyſtem of arable management that moſtly prevails in this kind of land, and by which ſome of the beſt land in the kingdom is condemned to be unemployed every third year; and the farmer who occupies it is compelled to pay three years rent in taxes, for two years uſe of it, and of courſe to maintain his family, ſervants, cattle, and implements of huſbandry, every third year, without having any return from the land. It is, therefore, impoſſible that lands of this ſort can ever be cultivated to the greateſt advantage, while they remain in their preſent ſtate. See INCLOSING.

It is obſerved by Mr. Marſhall that "abſurd as the common field ſyſtem is, in almoſt every particular, at this day, it was admirably ſuited to the circumſtances of the times in which it originated, the plan having been conceived in wiſdom and executed with accuracy as appears in numberleſs inſtances, even at this diſtance of time."

It is remarked that in the weſtern extreme of the iſland the common field ſyſtem has never, perhaps, been adopted; has certainly never been prevalent, as in the more central parts of England. There, a very different uſage would ſeem to have been early eſtabliſhed, and to have continued to the preſent time; when lords of manors have the privilege of letting off the lands of common paſtures, to be broken up for corn, the tenant being reſtricted to two crops; after which the land is thrown open again to paſturage. And it is at leaſt probable, that the lands of that country have been cleared from wood and brought into a ſtate of cultivation through ſimilar means. At preſent they are judiciouſly laid out, in farms of different ſizes, with ſquare ſtraight-lined incloſures, and with detached farm ſteads ſituated within their areas; the villages being generally ſmall and mean; the mere reſidence of labourers. Theſe are circumſtances which ſtrongly evince that the common field ſyſtem never took place in this part of the iſland, as it did in the more central parts.

But during the two laſt centuries, more particularly within the laſt, the feudal organization, having loſt its original baſis, has itſelf been mouldering away. A great majority of the appropriated common field lands and commons have been partially or wholly incloſed, either by piecemeal, each proprietor incloſing his own ſlip (a very inconvenient mode of incloſure); or by *general conſent*: the whole of the proprietors agreeing to commit their lands to the care and judgment of arbiters or commiſſioners; who, reſtoring the fields to their original intirety, reparcelled them out, in a manner more convenient to the ſeveral proprietors, and laid each man's portion, which had conſiſted of numberleſs narrow ſlips, in one or more well-ſhaped grounds, or by *acts of parliament*, whereby not only common fields, common meadows, and ſtinted paſtures, but unſtinted commons alſo, have been appropriated, by commiſſioners named in, or choſen in purſuance of, each reſpective act, who, throwing back the entire townſhip to its original ſtate, laid it out afreſh, according to the directions of the act and their own judgment.

COMMON *Field Huſbandry*, that ſort of cultivation which is practiſed in common fields. See HUSBANDRY. It has been obſerved in the "Agricultural Report of Wiltſhire," that the introduction of the common field huſbandry ſeems to have been very ſlow and progreſſive; and that the diſperſed ſituation and ſmallneſs of the pieces, of the common field lands now in cultivation, evidently ſhew that the occupiers began with tilling a ſingle acre, as one day's work for a plough, or perhaps only half an acre each; and that, as a want of corn increaſed, this cultivation was augmented until they had cultivated all that was moſt proper for that purpoſe, ſtill leaving thoſe parts which were leſs fit for the plough, or more diſtant from home, in a conſtant ſtate of commonage, but by mutual agreement keeping the cattle out of the cultivated parts till after harveſt. This was, probably, the origin of common fields. It does not ſeem probable, that any improved methods of cultivation can be adopted on common field lands, until the ſyſtem of common field huſbandry is aboliſhed. See COMMON and COMMON *Field Lands*.

COMMON *Meadows* and *Paſtures*, are ſuch meadows and paſtures as are held in a ſtate of commonage. It is remarked, by the author of the "Agricultural Survey of Wiltſhire," that, by the ſame kind of mutual agreement, as is ſtated in ſpeaking of common field lands, thoſe who have rights ſhut up, and in ſome caſes incloſed, ſuch parts of their common paſtures as were moſt proper to mow for hay, dividing them into certain ſpecific quantities, either by land-marks, or by lot, for mowing, and ſuffering the common herd of cattle to feed there again as ſoon as the hay was carried off, till it was time to lay them up for a new crop: and that this was the origin of common meadows. And that the mutual agreements, originally founded in neceſſity, became, when approved by the lords, and obſerved for a length of time by the tenants, what are called "cuſtom of manors," conſtituting the very eſſence of the court baron, or manorial court, by which both lord and tenants were and are ſtill bound; and of which, though the lord or his ſteward is the judge, the tenants are the jury, the cuſtom of the manor equally binding both.

COMMON, *Communis*, in a general ſenſe, ſomething that belongs to all alike; is owned or allowed by all; and is not confined to this more than that.

In which ſenſe, *common* ſtands oppoſed to *proper*, *peculiar*, &c. Thus, the earth is ſaid to be our *common* mother; in the firſt, or golden age, all things were in *common*, as well as the ſun and elements; the name animal is common to man and beaſt; that of ſubſtance to body and ſpirit. Philoſophers diſpute whether there be any ſuch thing as *common* notions, innate, or impreſſed on the mind by nature herſelf; or whether our ideas are all adventitious. See IDEA.

COMMON, *Communia*; (i. e. *quod ad omnes pertinet*) in *Law*, ſignifies that ſoil, the uſe whereof is *common* to a particular town or lordſhip: or it is a profit that a man hath in the land of another perſon, uſually in common with others; or a right or privilege, which one or more perſons claim to take or uſe, in ſome part or portion of that which another man's lands, waters, woods, &c. do naturally produce; without having an abſolute property in ſuch land, waters, wood, &c. It is called an "incorporeal right," which lies in "grant," as if originally commencing on ſome agreement between lords and tenants, for ſome valuable purpoſes; which by age being formed into a preſcription, continues, although there be no deed or inſtrument in writing which proves the original contract or agreement. 4 Co. 37. 2 Inſt. 65. 1 Vent. 387. And there is not only common of PASTURE, which the word "common," in its moſt uſual acceptation, ſignifies; but alſo *common* of PISCARY, *common* of ESTOVERS, *common* of TURBARY, &c. And in all caſes of *common*, the law doth much reſpect the cuſtom of the place: for there the rule is, *conſuetudo loci eſt obſervanda*. 7 Rep. 5.

COMMON *of paſture*, is a right of feeding one's beaſts on another's land; for in thoſe waſte grounds, uſually called commons, the property of the ſoil is generally in the lord of the manor; as in "common fields," it is in the particular tenants. This kind of common is divided into *common* in groſs, *common* appendant, *common* appurtenant, and *common per cauſe de vicinage*.

COMMON *in groſs*, is a liberty to have *common* alone, that is without any land or tenement in another man's land, granted either to a perſon for life or to him and his heirs. This is commonly paſſed by deed, or ſpecialty, and claimed by preſcriptive right.

Common *appendant*, and Common *appurtenant*, are uſually confounded; both being defined to be a liberty of *common* appertaining to, or depending on, ſuch or ſuch a freehold; which *common* muſt be taken with beaſts *commonable:* as horſes, oxen, &c. being accounted fitteſt for the plowman; and not with goats, geeſe, and hogs. Others diſtinguiſh between the two, thus; *common appurtenant* may be ſevered from the land whereto it appertains; and is where the owner of land has a right to put in other beaſts not *commonable;* as hogs, goats, &c. which neither plough nor manure the land. Whereas *common appendant*, according to lord Coke, had its original in the following manner:

"When a lord enfeoffed another in arable lands to hold of him in ſoccage; the feoffee, to maintain the ſervice of his plough, had at firſt, by courteſy of his landlord, *common* in his waſtes, for neceſſary beaſts to eat and compoſt his lands; and that for two cauſes; 1°. Becauſe it was tacitly implied in the feoffment; by reaſon the feoffee could not till, or compoſt his paſture: by conſequence, therefore, the feoffee had, as a thing neceſſary, or incident, *common* in the waſtes, or lands of the lord. 2°. For the maintenance and advancement of tillage."

Common appendant belongs only to ancient arable land, and not to a houſe, meadow, paſture, &c; and it is of common right. But it is not common appendant, unleſs it hath been appendant time out of mind. 1 Danv. 746. It may be upon condition; for all the year, or for a certain time, or for a certain number of beaſts, &c. by uſage; though it ought to be for ſuch cattle as plough and compoſt the land to which it is appendant. 1 Danv. 797. Common appendant may be to common in a field after the corn is ſevered, till the ground is reſown, and it may be to have common in a meadow after the hay is carried off, till Candlemas, &c. Yelv. 185. This common, which in its nature is not reſtricted by number, may be limited by cuſtom as to the beaſts; whereas common appurtenant ought always to be for thoſe levant and couchant, and may be *ſans* number. Plowd. 161. A man may preſcribe to have common appurtenant for all manner of cattle, at every ſeaſon in the year. 25 Aſſ. 8. He who hath common appendant or appurtenant can keep but a number of cattle proportionable to his land; for he can common with no more than the lands to which his common belongs is able to maintain. 3 Salk. 93.

Common *pur cauſe de vicinage*, i. e. by reaſon of neighbourhood, is the liberty that the tenants of one lord in one town, have to *common* with the tenants of another lord in another town.

But it is to be obſerved, that thoſe who claim this kind of *common*, (which is uſually called *intercommoning)* may not put their cattle into the *common* of the other lord, for then they are diſtrainable; but, turning them into their own fields, if they ſtray into their neighbour's *common*, they muſt be ſuffered.

The inhabitants of one town or lordſhip may not put in as many beaſts as they will, but with regard to the freehold of the inhabitants of the other; for otherwiſe it were no good neighbourhood, upon which all this depends. Terms de Ley. If one lord encloſes the common, the other town cannot then common; but though the common of vicinage is gone, common appendant remains. 4 Rep. 38. 7 Rep. 5. Every common pur cauſe de vicinage is a common appendant. 1 Danv. Abr. 799. This is indeed only a permiſſive right, intended to excuſe what in ſtrictneſs is a treſpaſs in both, and to prevent a multiplicity of ſuits. And therefore either townſhip may encloſe and bar out the other, though they have intercommoned time out of mind. Blackſt. Com. ii. 34.

The property of the ſoil in the "common" is entirely in the lord; and the uſe of it jointly in him and the commoners. Lords of manors may depaſture in commons where their tenants put in cattle: and a preſcription to exclude the lord is againſt law. 1 Inſt. 122. The lord may agiſt the cattle of a ſtranger in the common by preſcription; and he may licenſe a ſtranger to put in his cattle, if he leaves ſufficient room for the commoners. 1 Danv. 795. 2 Mod. 6. The lord may alſo ſurcharge, &c. an overplus of the common; and if, where there is not an overplus, the lord ſurcharge the common, the commoners are not to diſtrain his beaſts; but muſt commence an action againſt the lord. F. N. B. 125. The lord may diſtrain when the common is ſurcharged, and bring action of treſpaſs for any treſpaſs done in the common. 9 Rep. 113. A lord may make a pond on the common, though he cannot dig pits for gravel or coal; the ſtatutes of approvement extending only to incloſure. 3 Inſt. 204. 9 Rep. 112. 1 Sid. 106. If the lord makes a warren on the common, the commoners may not kill the conies; but are to bring their action, for they may not be their own judges. 1 Rol. 90. 405. By ſtatute of Merton (20 H. III. c. 4.) lords may "approve" againſt their tenants, *viz.* incloſe part of the waſte, &c. and thereby diſcharge it from being common, leaving common ſufficient; and neighbours as well as tenants, claiming common of paſture, ſhall be bound by it. If the lord incloſes on the common, and leaves not common ſufficient, the commoners may not only break down the incloſures, but may put in their cattle, although the lord ploughs and ſows the land. 2 Inſt. 88. 1 Rol. Abr. 406. By ſtat. 29 Geo. II. c. 36. Owners of commons, with the conſent of the majority, in number and value, of the commoners; the majority of the commoners, with conſent of the owners, or any perſons, with the conſent of both, may incloſe any part of a common for the growth of wood. If the wood be deſtroyed, the offender may be puniſhed according to ſtat. 1 Geo. 1. c. 48.; if not convicted in ſix months, the owner ſhall have ſatisfaction from the adjoining pariſhes, &c. as for fences overthrown by ſtat. Weſtm. 2. Perſons cutting wood on commons ſhall incur the ſame penalty. And by ſtat. 31 Geo. 2. c. 41, the recompence is to be paid to perſons intereſted, in proportion to their intereſt. A commoner hath only a ſpecial and limited intereſt in the ſoil, but yet he ſhall have ſuch remedies as are commenſurate to his right; and therefore he may diſtrain beaſts damage-feaſant, bring an action on the caſe, &c.; but not being abſolute owner of the ſoil, he cannot bring a general action of treſpaſs for a treſpaſs done upon the common. A commoner cannot do any thing on the ſoil which tends to the melioration or improvement of the common, as cutting down of buſhes, fern, &c. 1 Sid. 251. 12 Hen. VIII. 2. 13 Hen. VIII. 15. Therefore, if a common every year in a flood is ſurrounded with water, the commoner cannot make a trench in the ſoil to avoid the water, becauſe he has nothing to do with the ſoil, but only to take the graſs with the mouth of the cattle. 1 Rol. Abr. 405. 2 Bulſt. 116. Every commoner may break the common if it be incloſed; and although he does not put his cattle in at the time, yet his right of commonage ſhall excuſe him from being a treſpaſſer. Lit. Rep. 38. 1 Rol. Abr. 406. If a tenant of the freehold ploughs it, and ſows it with corn, the commoner may put in his cattle, and with them, eat the corn growing upon the land: ſo if he lets his corn lie in the field, beyond the uſual time, the other commoners may, notwithſtanding, put in their beaſts. 2 Leon. 202, 203. The commoner cannot uſe common except with his own proper cattle; but if he hath not cattle to manure the land, he may common other cattle to manure it, and uſe the common with them; for, by the loan, they are in a manner made his own cattle. 1 Danv. 798. A commoner may diſtrain beaſts put into the common by a ſtranger, or every commoner may bring action of the caſe, where damage is received. 9 Rep. 11. But one commoner cannot diſtrain the cattle of another commoner, though he may thoſe of a ſtranger, who hath no right to the common. 2 Lutw. 1238. See SURCHARGE *of Common,* and DISTURBANCE *of Common.*

Upon agreement between two commoners to incloſe a common, a party having intereſt, not privy to the agreement, will not be bound; but one or two wilful perſons ſhall not hinder the public good. Chan. Rep. 48. Commons muſt be driven yearly at Michaelmas, or within 15 days after; infected heifers and ſtone-horſes under ſize, &c. are not to be put into commons, under forfeiture, by ſtat. 32 Hen. VIII. c. 13. New erected cottages, though they have four acres of ground laid to them, ought not to have common in the waſte. 2 Inſt. 740. In law-proceedings, where there are two diſtinct commons, the two titles muſt be ſhewn: cattle are to be alleged commonable; and common ought to be in lands commonable; and the place is to be ſet forth where the meſſuage and lands lie, &c. to which the common belongs. 1 Nelſ. 462, 463. By ſtat. 13 Geo. III. c. 81. in every pariſh where there are "common field-lands," all the arable lands lying in ſuch fields ſhall be cultivated by the occupiers, under ſuch rules as three-fourths of them in number and value (with the conſent of the land and tithe-owners) ſhall appoint, by writing under their hands; the expence to be borne proportionably, under the management of a field-maſter, or field-reeve, to be appointed annually in May. For other particulars, ſee Jacob's Law Dict. by Tomlins.

COMMON, in *Geometry,* is applied to an angle, line or the like, which belongs equally to two figures, or makes a neceſſary part of both.

COMMON, in *Grammar,* denotes the gender of nouns which is equally applicable to both ſexes, male and female.

Such is that of *parens,* parent; which is either maſculine, or feminine, as it is uſed to ſignify either father, or mother.

The Latin grammarians, beſides this, which they call the *common of two,* alſo make a *common of three;* which extends to maſculine, feminine, and neuter.

COMMON, *Communis,* in *Ancient Muſic,* was an appellation given to the ſeventh ſpecies of the diapaſon. See DIAPASON.

COMMON *Bail.* See BAIL.

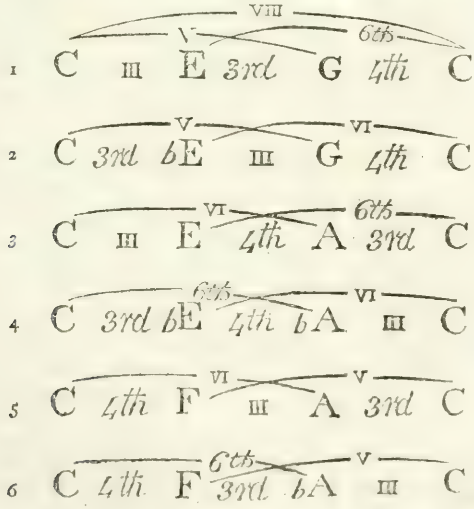
COMMON *Barretor.* See BARATRY.

COMMON *Bench.* The court of Common Pleas was anciently called *Common Bench,* becauſe the pleas of controverſies between common perſons were there tried and determined.

In law books and references, the court of Common Pleas is written C. B. from *communi banco,* or C. P.: and the juſtices of that court are ſtyled *juſticiarii de banco.* See COURT and *Common* PLEAS.

COMMON *Centre of Gravity,* in *Mechanics.* See CENTER *of Gravity.*

COMMON *Chord,* in *Muſic,* is ſometimes uſed to denote the third, fifth, and octave of any note, conſidered as a baſs. It will afford ſome light into the compoſition of chords, to exhibit all the poſſible variations in the order or arrangement of the concord, major *third* (III), minor *third* (3d), and minor *fourth* (4th), conſtituting the common chord in the following manner, *viz.*



the common chord.

the common chord minor.

the chord of ſixth, or $^{6}_{3}$.

the chord of $^{b6}_{b}$ or $^{b6}_{b3}$.

the chord of $^{6}_{4}$.

the chord of $^{b6}_{4}$.

By a compariſon of the ſeveral chords in the firſt arrangement above, it will appear, that when the four notes, C, E, G, and C, conſtituting the common chord, are ſounded together, all of the ſeven concords, viz. 3d, III, 4th, V, 6th, VI and VIII are in reality heard between the different notes, except the VI: and this circumſtance, combined with the III being above the baſs or loweſt note, ſeem eſſential to a full or common chord. In the ſecond arrangement, or C, $\flat$ E, G and C, it will be perceived, that all the concords are heard except the 6th; and this, combined with the third above the baſs note, conſtitutes the common chord of the minor mode. In the third arrangement, it will be ſeen, that there is no V produced, while a III occupies the place immediately above the baſs note, being the chord of ſixth. The fourth arrangement will alſo be found without a V, but with the 3d next the baſs, conſtituting the chord $^{\flat 6}_{\flat}$. The fifth arrangement will be found without a 6th, and with no third (but a 4th), next to the baſs, and this conſtitutes the chord $^{6}_{4}$. And laſtly, the ſixth arrangement will be found without a VI, or a third above the baſs, which conſtitutes the chord $^{\flat 6}_{4}$.

In performances by voices and perfect inſtruments, as violins, violincellos, &c. theſe ſeveral chords will be all heard *perfect;* and in each of the ſix caſes, a union or blending of the ſix concords, almoſt ſimilar to a ſingle ſound, will be perceived, but much more delightful to the ear; the characteriſtic differences of which conſtitute the character of the common chord and its five inverſions, as above. But upon the common keyed inſtruments, ſuch as organs, piano-fortes, harpſichords, &c. which contain but twelve ſounds within the octave, it is impoſſible that theſe ſingle or compound chords can all be heard perfect, but the greater part of the whole of them muſt be tempered or ſlightly altered from the true chord (ſee Temperament). If, for inſtance, the III C E above, were ſharpened ſeven ſchiſmas, or 7Σ, which is very nearly the caſe in *Equal Temperament* (which ſee), the 3d E G flattened 8Σ, and the 4th G C ſharpened Σ; the common chord, or firſt arrangement upon ſuch an inſtrument, would produce the following tempered concords, *viz.* $3d - 8\Sigma$, $III + 7\Sigma$, $4 + \Sigma$, $V - \Sigma$, and $6th - 7\Sigma$, combined with VIII; which chords, combined and blended, impreſs upon the ear the peculiar ſenſation of the common chord in this temperament. In the ſecond arrangement, or common chord minor, the effect produced will depend upon the union of the following tempered chords, viz. $3d - 8\Sigma$, $III + 7\Sigma$, $4th + \Sigma$, $V - \Sigma$, $VI + 8\Sigma$ and VIII. A common chord C E G C, upon an inſtrument tuned according to earl Stanhope's temperament, (ſee Philoſophical Magazine, vol. xxviii. p. 141) will be found to conſiſt of the following perfect chords, *viz.* 3d, III, 4th, V, 6th, and VIII; whence his lordſhip denominates his key of C major to be perfect (ſee Stanhope Temperament); but if we conſider the ſecond arrangement, or common chord of C minor, upon one of his lordſhip's inſtruments, we ſhall find $3d - 10\frac{1}{2}\Sigma$, $III + 10\frac{1}{2}\Sigma$, 4th, V, $VI + 10\frac{1}{2}\Sigma$, and VIII to conſtitute this chord, nearly, the very ſmall interval *minute* (*m*) only, being in any caſe omitted. Thus it will be eaſy to compare the effect of any inverſions of the common chord, in this, or any other temperament of the ſcale which may be propoſed.

Common *Clerk.* See Town *Clerk.*

Common *Crier.* See Crier.

Common *Council.* See *Mayor's* Courts.

Common *Day,* in plea of land, ſignifies an ordinary day in court, as *octabis Hilarii, quindena Paſchæ,* &c. It is mentioned in 13 Rich. II. ſtat. 1. cap. 17. and in the ſtatute 51 Hen III. concerning general days in bank. *Blount* and *Cowel.*

Common, *Diſturbance of.* See Disturbance *of Common.*

Common *Duct,* in *Anatomy.* See Ductus *Communis.*

Common, *Eſtate in.* See Estate.

Common *of Eſtovers.* See Estovers.

Common *Field-land.* See Common *ſupra.*

Common *Fine,* in *Law,* a certain ſum of money, which the reſiants within the liberty of ſome leets pay to the lord thereof; called in ſome places, *head-ſilver;* in others, *cert-money,* or *certum letæ,* and *head-pence.*

It was firſt granted to the lord towards the charge of his purchaſe of the court-leet; whereby the reſiants have now the conveniency of doing their ſuit within their own manors, without being compelled to go to the ſheriff's turn.

Common *in Groſs.* See Common *ſupra.*

Common *Hunt,* the chief huntſman belonging to the lord mayor and aldermen of London.

Common *Informer.* See Informer.

Common *Intendment,* in *Law,* the *common* underſtanding, meaning, or conſtruction of any thing: without ſtraining it to any foreign, remote, or particular ſenſe: and *Bar to Common Intendment,* is an ordinary, or general bar, which is commonly an anſwer to the declaration of the plaintiff. See Bar and Intendment.

Common *Jury.* See Jury.

Common *Law,* that body of rules generally received, and held as law in this nation, in contradiſtinction to the ſtatute, or written law, and including not only general cuſtoms, or the common law properly ſo called; but alſo the particular cuſtoms of certain parts of the kingdom, and likewiſe thoſe particular laws, that are by cuſtom obſerved only in certain courts and juriſdictions.

The common law is grounded upon the general cuſtoms of the realm, and comprehends the law of nature, the law of God, and the principles and maxims of the law: it is founded upon reaſon, and it is ſaid to be the perfection of reaſon, acquired by long ſtudy, obſervation, and experience, and refined by learned men in all ages. It is juſtly regarded as the common birth-right, which the ſubject has for the ſafe-guard and defence, not only of his goods, lands, and revenues, but of his wife and children, body, fame, and even life. Co. Litt. 97, 142. Treatiſe of Laws, p. 2. According to Hale, the common law of England is the common rule for adminiſtering juſtice within this kingdom, and aſſerts the king's royal prerogatives, and likewiſe the rights and liberties of the ſubject. It is, in general, that law by which the determinations in the king's "Ordinary courts" are guided; and this directs the courſe of deſcents of lands; the nature, extent, and qualifications of eſtates, together with the manner and ceremonies of conveying them from one to another; the forms, ſolemnities, and obligations of contracts; the rules and directions for the expoſition of deeds, and acts of parliament; the proceſs, proceedings, judgments, and executions of our courts of juſtice; alſo the limits and bounds of courts, and juriſdictions; the ſeveral kinds of temporal offences and puniſhments, and their application, &c. Hale's Hiſt. of the Common Law, p. 24—44, 45.

As to the origin of the common law, which, adopting the expreſſion of lord chief-juſtice Hale, is as undiſcoverable as the head of the Nile; our ancient lawyers, and particularly Forteſcue, warmly inſiſt, that the cuſtoms, which conſtitute our common law, are as old as the primitive Britons, and that they have been continued down, through the ſeveral mutations of government and inhabitants, to the preſent time, unchanged and unadulterated. This, ſays judge Blackſtone, may be the caſe as to ſome; but, in general, as Mr. Selden obſerves, this aſſertion muſt be underſtood with many grains of allowance; and ought only to ſignify, as the truth ſeems to be, that there never was any formal exchange of one ſyſtem of laws for another; though, doubtleſs, by the intermixture of adventitious nations, the Romans, the Picts, the Saxons, the Danes, and the Normans, they muſt have inſenſibly introduced and incorporated many of their own cuſtoms with thoſe that were before eſtabliſhed; thereby in all probability improving the texture and wiſdom of the whole, by the accumulated wiſdom of divers particular countries. Accordingly, lord Bacon obſerves, that our laws are as mixed as our language; and, as our language is ſo much the richer, the laws are the more complete. And, indeed, our antiquaries and early hiſtorians do all poſitively aſſure us, that our body of laws is of this compounded nature.

After the decay of the Roman empire, it has been ſaid, Britain became invaded by three kinds of German people, *viz.* the Saxons, Angles, and Jutes. From the Jutes deſcended the men of Kent, and thoſe of the Iſle of Wight; from the Saxons came the people called the Eaſt, South, and Weſt Saxons; and from the Angles came the Eaſt Angles, Mercians, and Northumbrians.

Now, as each people had its peculiar cuſtoms, ſo each inclined to different laws; whereof, thoſe of the Weſt Saxons and Mercians, who inhabited the midland counties, were, upon the diſſolution of the heptarchy, and eſtabliſhment of a monarchy, preferred to the reſt, and acquired the common appellation of *Jus Anglorum.* Their particular names were *Weſt Saxon-lage*, and *Merchen-lage.*

The firſt Saxon laws publiſhed in England were thoſe of king Ethelbert, in the ſixth century. Three hundred years after, king Alfred, whom our hiſtorians call *magnus juris Anglicani conditor*, having united the heptarchy, and rendered himſelf maſter of the whole nation, made a collection from among the numerous laws and cuſtoms of the ſeveral provinces of his domains, which were grown ſo various; and commanded them to be obſerved throughout his kingdom. This collection was denominated *folk-right*, and ſoon after the *common law*; as being *common* to the whole nation.

This was written in Alfred's *dome-book*, or *liber judicialis*, which was deſigned for the general uſe of the whole kingdom.

This book is ſaid to have been extant in the reign of king Edward IV.; but has ſince been unfortunately loſt. It contained, as we may reaſonably imagine, the principal maxims of the common law, the penalties for miſdemeſnors, and the forms of judicial proceedings.

By theſe laws the nation was governed for a conſiderable time, till, being at length ſubdued by the Danes, the cuſtoms of thoſe people were introduced, and incorporated with the reſt. Hence the code of Alfred in many provinces fell into diſuſe, or, at leaſt, was mixed and debaſed with other laws of a coarſer alloy: and thus a new form of *common* law aroſe, called *Dane-lage.*

The three ſyſtems of law above recited, viz. the *Dane-lage*, principally maintained in ſeveral of the midland counties and alſo on the eaſtern coaſt; the *Weſt Saxon-lage*, which was much the ſame with the code compiled by Alfred, and which obtained in the counties to the ſouth and weſt of the iſland, from Kent to Devonſhire, being the municipal law of the far moſt conſiderable part of Alfred's dominions, and particularly of Berkſhire, the ſeat of his peculiar reſidence; and the *Merchen-lage*, obſerved in many of the midland counties, and thoſe bordering on the principality of Wales, the retreat of the ancient Britons, and therefore probably intermixed with the Britiſh or Druidical cuſtoms; were in uſe about the beginning of the eleventh century. The northern provinces were at this time under a diſtinct government. In proceſs of time king Edgar begun what his grandſon Edward the Confeſſor, on this account called *legum Anglicanarum reſtitutor*, completed; *viz.* to form one digeſt or body of laws to be obſerved throughout the whole kingdom. This ſeems to have been only a new edition, or freſh promulgation of Alfred's *dome-book*, with ſuch additions and improvements as the experience of a century and a half had ſuggeſted.

The Danes being afterwards, in their turn, overcome by the Normans; the Conqueror, on a review of the ſeveral laws and cuſtoms that then obtained, abrogated ſome, and aboliſhed others; adding ſome of his own country laws.

His ſon, William Rufus, broke through the ancient laws and cuſtoms which his father had eſtabliſhed; but his next ſon, Henry I. excluded the civil cuſtoms which his brother had introduced, and reſtored the laws of Edward the Confeſſor, with thoſe amendments made by his father, under the advice of his barons. Theſe were afterwards confirmed in ſucceeding reigns.

Hence is derived that ſyſtem of maxims and unwritten cuſtoms, now known by the name of the *common law*, which is of Saxon parentage; though the cuſtoms and maxims themſelves are of higher antiquity than memory or hiſtory reach; many of them being as old as the primitive Britons. The name of common law was given to it; either in contradiſtinction to other laws, as the ſtatute law, the civil law, the law merchant, and the like; or, more probably, as a law common to all the realm, the *jus commune* or folk-right mentioned by king Edward the Elder, after the abolition of ſeveral provincial cuſtoms and particular laws.

The *common law* of England is, properly, the common cuſtoms of this kingdom; which, by length of time, have obtained the force of laws.

The goodneſs of a cuſtom depends upon its having been uſed time out of mind; or, in the ſolemnity of our legal phraſe, time whereof the memory of man runneth not to the contrary. This gives it its weight and authority; and of this nature are the maxims and cuſtoms which compoſe the common law, or *lex non ſcripta*, of this kingdom. This unwritten, or common law, is properly diſtinguiſhed into three kinds; 1. General cuſtoms, which are the univerſal rule of the whole kingdom, and form the common law, in its ſtricter and more uſual ſignification. 2. Particular cuſtoms, which for the moſt part affect only the inhabitants of particular diſtricts. 3. Certain particular laws; which by cuſtom are adopted and uſed, by ſome particular courts, of pretty general and extenſive juriſdiction. See CUSTOM.

Some have divided the common law into two principal grounds or foundations; *viz.* 1. Eſtabliſhed cuſtoms; ſuch as that, where there are three brothers, the eldeſt brother ſhall be heir to the ſecond, in excluſion of the youngeſt; and, 2. Eſtabliſhed rules and maxims; as, that the king can do no wrong; that no man ſhall be bound to accuſe himſelf; and the like. But judge Blackſtone obſerves, that theſe are one and the ſame thing. For the authority of theſe maxims reſts entirely upon general reception and uſage; and the only method of proving, that this or that maxim is a rule of the common law, is by ſhewing that it hath been always the cuſtom to obſerve it. See CUSTOM.

It is called *lex non ſcripta*, the *unwritten law*: not but that we have moſt of it written in the old Norman dialect, and the monuments and evidences of our legal cuſtoms are contained in the records of the ſeveral courts of juſtice, in books of reports and judicial deciſions, and in the treatiſes of learned ſages of the profeſſion, preſerved and tranſmitted from times of the higheſt antiquity; but becauſe it does not appear to be made by charter, or parliament; for thoſe are always matters of record. Its original inſtitution and authority are not ſet down in writing, but it receives its binding power and the force of law, by long and immemorial uſage, and by univerſal reception through the kingdom. See AUTHORITIES and REPORTS.

Beſide the *common law* of England in general, there are in divers parts of the nation particular cuſtoms, and common uſages, which have the force of *common law* among thoſe people, who have retained them: ſuch as the Borough-Engliſh, Gavel-kind, &c.—Where the *common law* is ſilent, there the STATUTE-*law* ſpeaks. See STATUTE.

All trials at *common law* are by a jury of twelve men.

Among the ancient and moſt eminent writers on common law we may ſelect and enumerate the following. Britton wrote his learned book of the common law of this realm by the king's command, and it runs in his name, correſponding to the inſtitutions of the civil law, which Juſtinian aſſumes to himſelf, though compoſed by others under his direction. This Britton is mentioned by Gwin to have been biſhop of Hereford. Bracton, a great lawyer in the time of Henry III., wrote a very learned treatiſe of the common law of England, held in great eſtimation; and he was ſaid to be lord chief-juſtice of the kingdom. The famous and learned Glanvil, lord chief-juſtice in the reign of Henry II., wrote a book of the common law, which is ſaid to be the moſt ancient compoſition extant on that ſubject. Beſides theſe, in the time of Edward IV. the renowned lawyer Littleton wrote his excellent book of "Engliſh Tenures." In the reign of king James I., the great oracle of the law, ſir Edward Coke publiſhed his learned and laborious "Inſtitutes" of our law, and commentary on Littleton. About the ſame time likewiſe Dr. Cowel, a civilian, wrote a ſhort inſtitute of our laws. In the reign of king George I., Dr. Tho. Wood, a civilian and common lawyer, and at laſt a divine, wrote an inſtitute of the laws of England, ſomewhat after the manner of the Inſtitutes of the civil law. And to mention no others, the late learned judge Blackſtone, in the reign of George III., publiſhed his "Commentaries" on the laws of England, the beſt analytic and moſt methodical ſyſtem of our laws, which was ever publiſhed; and equally adapted for the uſe of ſtudents, and of thoſe gentlemen who wiſh to acquire that knowledge of our laws, which is, in fact, eſſentially neceſſary for every one. See biographical articles BRITTON, BRACTON, &c. &c.

COMMON *meaſure diviſor*, in *Arithmetic*, a number that exactly meaſures two other numbers, without a remainder. And the greateſt number that can meaſure any two other numbers, is called their greateſt common meaſure; thus 4 is the greateſt common meaſure of 8 and 12.

To find the greateſt common meaſure of two numbers; divide the greater by the leſs, and if there be no remainder, the leſs number is the meaſure required. If there be a remainder, divide the laſt diviſor by it, and thus proceed, till there be no remainder left, and the laſt diviſor is the greateſt common meaſure.

E. G. To find the greateſt common meaſure of 816 and 1488.

0

For algebraic quantities, the remainders are to be divided by their ſimple diviſors, and the quotients will be the quantities required.

E. G. Let the quantities be $a^2 + 2ab + b^2$ and $a^3 + 2a^2b + 2ab^2 + b^3$.

Divide the latter of theſe by the former in the following manner:

$$a^2 + 2ab + b^2)a^3 + 2a^2b + 2ab^2 + b^3(a$$
$$\underline{a^3 + 2a^2b + ab^2}$$

The remainder is - - - $+ ab^2 + b^3$, which being divided by b^2, its greateſt ſimple diviſor, given $a + b$; and by this divide $a^2 + 2ab + b^2$, and the quotient will be $a + b$, exactly, which is the common meaſure required. And if fractions are divided by their greateſt common meaſure, they will thus be reduced to their loweſt terms.

E. G. Let the fraction be $\frac{816}{1488}$: then divide the numerator and denominator by 48, the greateſt common meaſure, and the fraction will be reduced to $\frac{17}{31}$, its loweſt terms. Let the algebraic fraction be $\frac{a^2 + 2ab + b^2}{a^3 + 2a^2b + 2ab^2 + b^3}$; then, dividing the numerator and denominator by $a + b$ the greateſt common meaſure; and it will be reduced to $\frac{a + b}{a^2 + ab + b^2}$, its loweſt terms.

Theſe operations are founded on this principle, *viz.* that whatever quantity meaſures the whole and one part of another, muſt alſo meaſure the remaining part. For that quantity (whatever it is) which meaſures both the diviſor and dividend, muſt evidently meaſure $a^3 + 2ab + b^2$, being a multiple of the former; whence, by the above-cited principle, the ſame quantity, as it increaſes the whole dividend, muſt alſo meaſure the remaining part of it, $ab^2 + b^3$: but the diviſor, which we are ſeeking, being a compound one, we may caſt off the ſimple diviſor b^2, as not anſwering our purpoſe; whence $a + b$ appears to be the only compound diviſor which the caſe admits of; and this muſt be the common meaſure required, if the propoſed example admits of any ſuch.

COMMON, *Month*, *Motion*, *Nuiſance*, and *Object*. See the SUBSTANTIVES.

COMMON of *Paſture*. See PASTURE and COMMON.

COMMON of *Piſcary*. See PISCARY.

COMMON-PLACE *Book*, *Adverſaria*, among the learned, denotes a regiſter, or orderly collection of things which occur worthy to be noted, and retained in the courſe of a man's reading, or ſtudy; ſo diſpoſed, as that among a multiplicity of ſubjects, any one may be eaſily found.

Common-place-books are of great ſervice: they are a kind of promptuaries or ſtorehouſes, wherein to repoſit the moſt valuable parts of authors, to be ready at hand when wanted. Several perſons have their ſeveral methods of ordering them: but that which comes beſt recommended, is the method of that great maſter of order Mr. Locke. He has thought fit to publiſh it in a letter to M. Toiſnard; determined thereto, by the great conveniency and advantage he had found from it in twenty years experience; as well as by the recommendations and intreaties of many of his friends, who had likewiſe proved it.

The ſubſtance of this method we ſhall here give the reader; whereby he will be eaſily enabled to execute it himſelf.

The firſt page of the book you intend to take down the *common-places* in, is to ſerve as a kind of index to the whole; and to contain references to every place, or matter therein: in the commodious contrivance of which index, ſo that it may admit of a ſufficient copia, or variety of materials, without any confuſion, the whole ſecret of the method conſiſts.

In order to this the firſt page, as already mentioned, or for more room, the two firſt pages that front each other, are to be divided by parallel lines, into twenty-five equal parts; whereof every fifth line is to be diſtinguiſhed, by its colour, or ſome other circumſtance. Theſe lines are to be cut perpendicularly by others, drawn from top to bottom; and in the ſeveral ſpaces thereof the ſeveral letters of the alphabet, both capital and minuſcule, are to be duly written. The form of the lines and diviſions, both horizontal and perpendicular, with the manner of writing the letters therein, will be conceived from the following ſpecimen; wherein what is to be done in the book for all the letters of the alphabet, is here ſhewn in the firſt four, A, B, C, and D.

A	a		C	a	
	e			e	
	i			i	
	o			o	
	u			u	
B	a		D	a	
	e			e	
	i			i	
	o			o	
	u			u	

The index of the common-place book being thus formed, matters are ready for the inſertion of any thing in it. In order to this, conſider to what head, the thing you would enter is moſt naturally referred; in this head, or word, regard is had to the initial letter, and the firſt vowel that follows it; which are the characteriſtic letters on which the whole uſe of the index depends.

Suppoſe, *e. gr.* I would enter down a paſſage that refers to the head *beauty;* B, I conſider, is the initial letter, and *e* the firſt vowel; then looking upon the index for the partition B, and therein the line *e* (which is the place for all words whoſe firſt letter is B, and firſt vowel *e;* as *Beauty*, *Beneficence*, *Bread*, *Bleeding*, *Blemiſhes*, &c.), and finding no numbers down already to direct me to any page of the book where words of this characteriſtic have been entered, I turn forward to the firſt blank page I find, which in a freſh book, as this is ſuppoſed to be, will be page 2, and here I now write what I have occaſion for on the head *beauty;* beginning the head in the margin, and indenting all the other ſubſervient lines, that the head may ſtand out, and ſhew itſelf; this done, I enter the page where it is written. *viz.* 2, in the index, in the ſpace B *e*, from which time, the claſs B *e* becomes wholly in the poſſeſſion of the 2d and 3d pages, which are conſigned to letters of this characteriſtic.

Had I found any page or number already entered in the ſpace B *e*, I muſt have turned to the page, and have written my matter in what room was left therein: ſo, if after entering the paſſage on beauty, I ſhould have occaſion for *benevolence*, or the like, finding the number 2 already poſſeſſed of the ſpace of this characteriſtic, I begin the paſſage on benevolence in the remainder of the page; which not containing the whole, I carry it on to page 3, which is alſo for B *e*, and add the number 3 in the index. When the two pages deſtined for one claſs are full, look forward for the next backſide that is blank; if it be that which immediately follows, write at the bottom of the margin of the page filled, the letter *v* for *verte*, turn over; and the ſame at the top of the next page: and continue from this new page as before. If the pages immediately following be already filled with other claſſes, then write at the bottom of the page laſt filled, the letter *v*, with the number of the next blank page; and at the top of that page, the number of the page laſt filled; then entering that head in this new page, proceed as before. By theſe two numbers of reference, the one at the top, and the other at the bottom of the page, the diſcontinued matters are again connected. It may not be amiſs, every time you put a number at the bottom of a page, to put it likewiſe in the index. Now, if the head be a monoſyllable beginning with a vowel, the vowel is at the ſame time both the initial letter, and the characteriſtic vowel: thus the word *art* is to be wrote in A *a*. Mr. Locke omits three letters of the alphabet in his index, *viz.* K, Y, and W; which are ſupplied by C, I, U, equivalent to them: and as for Q, ſince it is always followed by an *u*, he puts it in the fifth place of Z; and ſo has no Z *u*, which is a characteriſtic that very rarely occurs. By thus making Q the laſt in the index, its regularity is preſerved, without diminiſhing its extent. Others chooſe to retain the claſs Z *u*, and aſſign a place for Q *u* below the index.

If any imagine, that thoſe hundred claſſes are not ſufficient to comprehend all kinds of ſubjects without confuſion, he may follow the ſame method, and yet augment the number to five hundred, by taking in one more characteriſtic to them.

But the inventor aſſures us, that in all his collections, for a long ſeries of years, he never found any deficiency in the index as above laid down. Other contrivances for commonplace books have been propoſed; but they are ſuch as will naturally occur to perſons converſant with the ſubject, and accuſtomed to orderly arrangement: and it is, therefore, needleſs to extend this article.

Common *Prayer*, is the liturgy of the church of England. Clergymen are obliged to uſe this liturgy in the ſervice of the church; and refuſing to do ſo, or uſing any other public prayers, is puniſhable by 1 Eliz. cap. 2. and every incumbent reſiding on his living and keeping a curate, is obliged, once every month at leaſt, to read the common prayer in his pariſh church, in his own perſon, under a forfeiture of 5*l.* for every failure, by the act of uniformity, 13 and 14 Car. II. cap. 4.; and by the ſame ſtat. every church is to be provided with a book of common prayer, under the penalty of 3*l.* a month, and the common prayer is to be read before every lecture. Every miniſter who ſpeaks any thing in derogation of this book ſhall, if not beneficed, be impriſoned one year for the firſt offence, and for life for the ſecond; and, if he be beneficed, he is liable to ſix months impriſonment, and the forfeiture of a year's value of his benefice; for the ſecond offence to deprivation and one year's impriſonment; and for the third offence to deprivation and impriſonment for life: and any perſon convicted of reviling it in plays, ſongs, or other open words, or of forcibly preventing its being read, or of cauſing any other ſervice to be read in its ſtead, ſhall forfeit for the firſt offence an hundred marks; four hundred for the ſecond; and for the third offence all his goods and chattels, and ſuffer impriſonment for life. Stat. 1 Eliz. cap. 2. See Liturgy.

Common *Weal* denotes "bonum publicum," or the public good, and is much favoured in our laws; and therefore many things are legally tolerated, with a view to the public good, which otherwiſe might not be done. Hence it is that monopolies are void in law, and that bonds and covenants to reſtrain free trade, tillage, and the like, are adjudged void. 11 Co. Rep. 50. Plowd. 25. Shep. Epit. 270.

Common *Year.* See Year.

COMMONABLE Lands, in *Agriculture*, are ſuch lands as are generally in ſome meaſure arable, and which belong, in property, to individuals who are known, and the limits of whoſe property are aſcertained: but which, in regard to their culture and mode of cropping, are ſubject to certain regulations, which cuſtom, for time immemorial, has eſtabliſhed, ſo as gradually to have acquired the force of law, to which rules every individual occupying ſuch property muſt adhere, until theſe old cuſtoms ſhall be abrogated, either by the unanimous conſent of all the individuals having a right to ſuch commonable lands, or by an expreſs ſtatute, obtained with their conſent, for the purpoſe of annulling them. In ſome countries, Dr. Anderſon ſays, it appears that not much leſs than one half of the whole arable lands are in this ſtate; although it is evident, by the concurring teſtimony of all the agricultural reports, that taking all theſe lands at an average, they do not afford half the produce the ſame lands would do, if they were put under the ordinary management that appropriated farmers are ſubjected to in their reſpective diſtricts: and not perhaps one tenth part of what they might eaſily be made to afford, within a very ſhort period of time, ſhould all other obſtructions to improvement be removed. It would be tireſome, he ſays, to enumerate all the facts that occur in the different agricultural ſurveys, tending to point out the pernicious tendency of this mode of tenure: but a few of them may be mentioned. In one place it is ſtated, that a few incloſures had been made, ſeemingly with the concurrence of all the parties concerned; but when the hedges had advanced nearly to become a fence, one of the commonable tenants went deliberately and pulled them up by the roots, and eradicated them entirely. In another caſe the pariſhioners having come to an agreement to ſow clover, after that practice had been univerſally acquieſced in for the ſpace of eighteen years, one of the farmers, occupying ſixteen acres of land, bought a large ſtock of lean ſheep in the month of May, and turned them on the clover crops, which were nearly in bloom, and no one could hinder him. In another caſe, where cuſtom had eſtabliſhed the practice of having one corn crop, and one fallow, alternately, the occupiers of the diſtrict came to an agreement to have two crops and a fallow alternately; but before the expiration of ten years, one of the farmers broke through the agreement, and turned his cattle upon the crops of beans, oats, and barley: in which plan he was followed by the reſt of his neighbours; and the crops were, in conſequence, totally deſtroyed on that part of the field, which, agreeable to the ancient cuſtom, ſhould have been that year in fallow. Theſe notices, while they tend to illuſtrate the nature of this particular kind of tenure, at the ſame time, he ſays, clearly demonſtrate its pernicious tendency to the public. No one, who has conſidered the ſubject for a moment, but will readily admit, that it were much for the intereſt of Britain that no ſuch practice exiſted in it: and that, of courſe, no time ſhould be loſt in endeavouring to eradicate it; for, were this effectually done, it muſt appear evident from the facts ſtated, that the total produce of the kingdom would be greatly augmented and improved. See Common.

COMMONALTY, comprehends one diſtinction of the civil ſtate; the nobility being the other; and like the nobility, includes ſeveral degrees of rank and condition. In Art. ſuper Chartas, 28 Ed. 1. c. 1., the words "Tout le commune de l'Engleterre," ſignify all the people of England. 2 Inſt. 539. But the term is generally uſed for the middle rank of the king's ſubjects, ſuch of the commons as are raiſed above the ordinary ſort, and having the management of offices, are by that means one degree below burgeſſes, who are ſuperior to them in order and authority:—and companies incorporated are ſaid to conſiſt of maſters, wardens, and commonalty, the firſt two being the chief, and the others ſuch as are uſually called of the livery. The ordinary people, and freeholders, or at beſt knights and gentlemen, under the degree of baron, have been, of late years, called "communitas regni," or "tota terræ communitas;" yet anciently, if we credit Brady, the barons and tenants in capite, or military men, were the community of the kingdom, and thoſe only were reputed as ſuch in our moſt ancient hiſtories and records. Brady's Gloſſ. to his Introd. to Eng. Hiſt.

COMMONE, in *Ancient Geography*, the name of an iſland in the Mediterranean, placed by Pliny on the coaſt of Ionia.

COMMONER, is uſed for a ſtudent in ſome univerſities, entered in a particular rank.

The word is alſo applied to a member of the houſe of commons, in contradiſtinction to a peer.

COMMONI, in *Ancient Geography*, a denomination given by Ptolemy to a people of Gallia Narbonnenſis, who inhabited the country, including the town of Tauroentium, the promontory of Cithariſtes, the town of Olbia, that of Forum Julii, &c.

COMMONS, in a general ſenſe, conſiſt of all ſuch men of property in the kingdom, as have not ſeats in the houſe of lords; every one of whom has a voice in parliament, either perſonally, or by his repreſentatives. In a free ſtate, ſays judge Blackſtone, every man, who is ſuppoſed a free agent, ought to be in ſome meaſure his own governor; and, therefore, a branch at leaſt of the legiſlative power ſhould reſide in the whole body of the people. And this power, when the territories of the ſtate are ſmall, and its citizens eaſily known, ſhould be exerciſed by the people in their aggregate or collective capacity; as was wiſely ordained in the petty republics of Greece, and the firſt rudiments of the Roman ſtate. But this will be highly inconvenient, when the public territory is extended to any conſiderable degree, and the number of citizens is increaſed. Thus when, after the Social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public aſſemblies, it became impoſſible to diſtinguiſh the ſpurious from the real voter, and from that time all elections and popular deliberations grew tumultuous and diſorderly; which paved the way for Marius and Sylla, Pompey and Cæſar, to trample on the liberties of their country, and at laſt to diſſolve the commonwealth. In ſo large a ſtate as ours, it is therefore wiſely contrived, that the people ſhould do that by their repreſentatives, which it is impracticable to perform in perſon; repreſentatives choſen by a number of minute and ſeparate diſtricts, wherein all the voters are, or eaſily may be, diſtinguiſhed.

Commons, in parliament, are the lower houſe, conſiſting of knights elected by the counties, and of citizens and burgeſſes by the cities and borough-towns. See Borough, Burgess, and Knight.

In theſe elections, anciently, all the people had votes; but in the 8th and 10th of king Henry VI. for avoiding tumults, laws were enacted, that none ſhould vote for knights but ſuch as were freeholders, did reſide in the county, and had forty ſhillings yearly revenue; equivalent to near 20*l.* a year of our preſent money: the perſons elected for counties to be *milites notabiles*, at leaſt eſquires, or gentlemen fit for knighthood; native Engliſhmen, at leaſt naturalized; and twenty-one years of age: no judge, ſheriff, or eccleſiaſtical perſon, to ſit in the houſe for county, city, or borough.

The *houſe of commons*, in Forteſcue's time, who wrote during the reign of Henry VI. conſiſted of upwards of 300 members: in ſir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 repreſentatives for Scotland were added; ſo that the whole number of members amounted to 558.

In conſequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole houſe of commons now conſiſts of 658 members: *viz.* 80 knights for 40 counties in England; 50 citizens for 25 cities (Ely ſending none, and London four); 334 burgeſſes for 167 boroughs, and 5 burgeſſes for 5 boroughs, *viz.* Abingdon, Banbury, Bewdley, Higham Ferrers, and Monmouth; 4 burgeſſes for the two univerſities of Oxford and Cambridge; 16 barons for the 8 cinque-ports, *viz.* Haſtings, Dover, Sandwich, Romney, Hythe, and their three branches, Rye, Winchelſea, and Seaford; 12 knights for 12 counties in Wales; 12 burgeſſes for 12 boroughs in that country; 30 knights for the ſhires of Scotland, and 15 burgeſſes for its boroughs; 64 knights and 36 burgeſſes for Ireland. For an account of the privileges of members of the houſe of commons, and other particulars, ſee Parliament.

Commons is alſo uſed in oppoſition to *nobles* or *peers*, viz. for all ſorts of perſons under the degree of a baron; including the orders of knights, eſquires, gentlemen, the ſons of the nobility, and yeomen. See each under its proper article, Esquire, Gentleman, Yeoman, &c.

Commons, *Doctors*. See College *of Civilians*.

Commons, *Proctor of the*. See Proctor.

Commons is alſo uſed for the ſtated and ordinary diet, or eating, of a college, inn of court, or other ſociety. See Inn, &c.

COMMONWEALTH. See Republic.

Commonwealth *of England*, in *Hiſtory*, a form of government introduced after the diſſolution of the monarchy by the death of Charles I., in 1649. The change of government ſeems to have been ſuggeſted in the preceding year by a council of officers, who took into conſideration a ſcheme called "The Agreement of the People;" being the plan of a republic to be ſubſtituted in the place of that government which they were demoliſhing; but the commonwealth was not eſtabliſhed till after the tragical event of the king's death. Soon after this event, the houſe of commons publiſhed an act to forbid the proclamation of Charles Stewart, eldeſt ſon of the late king, or any other perſon, on pain of high treaſon. On the ſame day the lords deſired a conference with the commons about ſettling the government and the adminiſtration of juſtice, the commiſſions of the judges having been determined by the king's death. The commons, without anſwering the meſſage, voted the houſe of lords to be uſeleſs and dangerous, and therefore to be aboliſhed. They only left the lords the privilege of being elected members of parliament, in common with other ſubjects. Thus, the parliament, which at firſt was compoſed of the king, 120 lords, and 513 commoners, was reduced to a houſe of commons, conſiſting of about 80 members, few of whom at the beginning had 500*l.* yearly income. Nevertheleſs, theſe few and inconſiderable members aſſumed the name of a parliament, and acted as if their body had been inveſted with the authority, which had before reſided in the king, lords, and commons. But they were previouſly diſpoſed and prepared for the buſineſs which they undertook to execute, and they were awed and ſupported by an army of near 50,000 men, formidable from its diſcipline and courage, as well as its number, and actuated by a ſpirit that rendered it dangerous to the aſſembly, which had aſſumed the command over it. It muſt be confeſſed, however, that in this parliament there were ſome men of diſtinguiſhed capacity and integrity, and that if they adopted erroneous principles, or purſued thoſe that were juſt and reaſonable to an unwarrantable extent, they were deſtitute neither of talents nor of influence to defend and ſupport them. The ſovereign authority, as they maintained, reſided originally in the people, by whom a part of it was committed to the kings, choſen to govern them according to law; and they alleged, that the king's abuſe of this truſt had broken the original contract between king and people, and that, in conſequence of this violation, the contract ſubſiſted no longer, but the ſovereign power reverted to the people, as to its original ſource. Conſidering themſelves as the repreſentatives of the people, they conceived that they had a right to change the form of the government, without any regard to the original contract annulled by the king in his violation of the laws. Upon theſe principles, the commons, aſſuming the name of parliament, voted, and afterwards enacted, that the kingly office ſhould be aboliſhed as unneceſſary, burdenſome, and dangerous, and that the ſtate ſhould be governed by the repreſentatives of the people in a houſe of commons without king or lords, and under the form of a commonwealth. The former oaths of allegiance and ſupremacy were aboliſhed, and a new oath was prepared, called "The Engagement," by which every man ſwore, that he would be true and faithful to the government eſtabliſhed, without king or peers. Juſtice was no longer to be adminiſtered in the king's name, but the name, ſtyle, and teſt of the writs were to be, "cuſtodes libertatis Angliæ, authoritate parliamenti;" a new great ſeal was to be made; new money to be coined; and, in a word, every thing was to be ſet aſide and aboliſhed, that bore any marks of royalty. A great ſeal was therefore made, on one ſide of which was ſeen the parliament ſitting, with this inſcription: "the great ſeal of the parliament of the commonwealth of England;" and on the other ſide, the arms of England and Ireland, with theſe words, "the firſt year of freedom by God's bleſſing reſtored." This ſeal was committed to a certain number of perſons, who were ſtyled "keepers of the liberties of England." And it was ordained, that, for the future, all public orders ſhould be diſpatched in the name of theſe keepers, under the direction of the parliament. The parliament alſo made choice of 39 perſons to form a council of ſtate for the adminiſtration of public affairs under the parliament; to this council all addreſſes were made; they gave orders to all generals and admirals, executed the laws, and digeſted all buſineſs before it was brought into parliament. They profeſſed to employ themſelves entirely in adjuſting the laws, forms, and plan of a new repreſentation; and as ſoon as they ſhould have ſettled the nation, they avowed their intention of reſtoring the power to the people, from whom, they acknowledged, they had wholly derived it. The parliament alſo erected a high court of juſtice, conſiſting of 60 members, to try ſome perſons of diſtinction, who were in their power. The commonwealth, thus formed and eſtabliſhed, found England compoſed into a ſeeming tranquillity by the terror of its arms. Foreign powers, occupied in wars among themſelves, had no leiſure nor inclination to interpoſe in the domeſtic diſſenſions of this iſland. The young king, poor and neglected, living ſometimes in Holland, ſometimes in France, ſometimes in Jerſey, indulged the hope, among his preſent diſtreſſes, of better fortune at ſome future period. The ſituation alone of Scotland and Ireland occaſioned any immediate inquietude to the new republic. As to the Scots, they were allowed for the preſent to take their own meaſures in ſettling their government; but Ireland demanded more immediately their efforts for ſubduing it. Cromwell, having obtained the appointment of lieutenant in that country by his intereſt in the council of ſtate, loſt no time in paſſing thither; and he proceeded with ſuch uninterrupted ſucceſs, that in the ſpace of nine months he had almoſt entirely ſubdued it. Afterwards, leaving the command of Ireland to Ireton, who governed that kingdom in the character of deputy, he haſtened home, and was declared captain-general of all the forces in England. Having received this honourable appointment, he immediately marched his forces and entered Scotland; where Charles, who had been invited thither, was making conſiderable progreſs, with an army of 16,000 men. Cromwell having gained a deciſive victory over the Scots in the battle of Dunbar, and having taken poſſeſſion of Edinburgh and Leith, followed the young prince in his march into England, and falling in with an army of about 30,000 men in the city of Worceſter, he either killed or took priſoners the whole Scottiſh army, and obliged the king to fly; and at length to make his eſcape from Shoreham in Suſſex, to Feſcamp in Normandy. The ruling members of the commonwealth were deſtitute of thoſe comprehenſive views which might qualify them for acting the part of legiſlators. They made ſlow progreſs in the work to which they profeſſed themſelves devoted, that of ſettling a new model of repreſentation and fixing a plan of government. The nation therefore began to apprehend, that they intended to eſtabliſh themſelves as a perpetual legiſlature, and to confine the whole power to 60 or 70 perſons, who called themſelves the parliament of the commonwealth of England. However, the republicans, by the turn of their diſpoſition, and by the nature of the inſtruments which they employed, ſhewed themſelves better qualified for acts of force and vigour than for the ſlow and deliberate work of legiſlation. Notwithſtanding the diſtreſſed ſtate of the kingdom, occaſioned by contending factions and by the devaſtation of civil wars, the power of England had never, in any period, appeared ſo formidable to the neighbouring kingdoms as it did at this time, in the hands of the commonwealth. A numerous army ſerved equally to retain every one in implicit ſubjection to eſtabliſhed authority, and to ſtrike a terror into foreign nations. The power of peace and war was lodged in the ſame hands with that of impoſing taxes. The military genius of the people had, by the civil conteſt, been rouzed from its former lethargy; and excellent officers were formed in every branch of ſervice. The confuſion into which all things had been thrown, had given opportunity to men of low ſtations to work through their obſcurity, and to raiſe themſelves by their courage to commands which they were well qualified to exerciſe, but to which their birth could never have entitled them. And while ſo great a power was lodged in ſuch active hands, it is no wonder that the republic was ſucceſsful in all its enterprizes.

Notwithſtanding all the ſucceſſes that attended the military operations of the commonwealth, both by ſea and land, ſome circumſtances occurred which widened the breach that had ſubſiſted for a conſiderable time between the parliament and the army. Cromwell alſo ſaw that the zealous republicans in the government entertained a jealouſy of his power and ambition, and were reſolved to bring him to a ſubordination under their authority. He, therefore, without ſcruple or delay, determined to prevent them. Accordingly he called a council of officers, under the pretence of expediting the eſtabliſhment of that free and equal government which parliament had ſo long promiſed to the people. In this council Cromwell had many friends, and alſo ſome opponents. The meaſure which he propoſed was debated by the officers; and during the debate, Cromwell received information, that the parliament was ſtill ſitting, and had come to a reſolution not to diſſolve themſelves, but to fill up the houſe by new elections; and that at this very time it was engaged in deliberations with regard to this expedient. Cromwell in a rage, haſtened to the houſe, taking with him a body of 300 ſoldiers, whom he arranged about the houſe. After waiting for ſome time in ſeeming ſuſpence, and profeſſing his reluctance in adopting the meaſure which he had previouſly determined to execute, that of diſſolving the parliament, he carried it into effect in the moſt rude and violent manner; and, without the leaſt oppoſition or murmur, though he loaded the parliament with the vileſt reproaches, for their tyranny, ambition, oppreſſion, and robbery of the public, he annihilated that famous aſſembly, which had filled all Europe with the renown of its actions, and with aſtoniſhment at its crimes, and the commencement of which was not more ardently deſired by the people than its final diſſolution. Parliament having been thus diſſolved, Cromwell might have aſſumed the adminiſtration of the government by an authority ſimilar to that with which he had diſmiſſed the parliament. But he choſe to proceed in his aſſumption of the ſovereign power by more cautious ſteps, and with ſome appearance of reſpect for the popular opinion. Accordingly, by the advice of his council of officers, he ſent ſummonſes to 128 perſons of different towns and counties of England, to five of Scotland, and ſix of Ireland; and he pretended by his ſole act and deed to devolve upon theſe the whole authority of the ſtate. This legiſlative power they were to exerciſe during 15 months; and they were afterwards to chooſe the ſame number of perſons, who might ſucceed them in that high and important office. They immediately voted themſelves a parliament, called by way of deriſion from Barebone, a leather-ſeller, one of their number, "Barebone's parliament;" and having their own conſent, as well as that of Oliver Cromwell, for their legiſlative authority, they now proceeded very gravely to the exerciſe of it. The members of this legiſlative aſſembly, of which Cromwell himſelf was aſhamed, though he had introduced into it ſeveral members entirely devoted to his own intereſt, found themſelves unequal to the burden impoſed upon them; and having met, by conſent, at an early hour, they agreed to diſſolve themſelves and to reſign the ſovereign authority into the hands from which they had received it. They haſtened, therefore, to Cromwell, along with Rouſe, their ſpeaker; and by a formal deed of aſſignment reſtored to him the ſupreme authority. The council of officers now propoſed to adopt another ſcheme of government, and to temper the liberty of a commonwealth by the authority of a ſingle perſon, who ſhould be known by the appellation of protector. Without delay, Lambert, who made this propoſition, prepared what was called "the inſtrument of government," containing the plan of this new legiſlature; and as it was ſuppoſed to be agreeable to the general, it was immediately voted by the council of officers. Cromwell was declared "Protector," and with great ſolemnity inſtalled in that high office. The chief articles of the forementioned inſtrument are theſe: a council was appointed, the number of which was not to exceed 21, nor to be leſs than 13 perſons. Theſe were to enjoy their office during life or good behaviour; and in caſe of a vacancy, the remaining members named three, of whom the protector choſe one. The protector was appointed ſupreme magiſtrate of the commonwealth; in his name all juſtice was to be adminiſtered; from him were all magiſtracy and honours derived; he had the power of pardoning all crimes, excepting murder and treaſon; to him the benefit of all forfeitures devolved. The right of peace, war, and alliance reſted in him, with the advice and aſſiſtance of his council. The power of the ſword was veſted in the protector jointly with the parliament, while it was ſitting, or with the council of ſtate in the intervals. He was obliged to ſummon a parliament every three years, and allow them to ſit five months without adjournment, prorogation, or diſſolution. The bills which they paſſed, were to be preſented to the protector for his aſſent; but if it were not obtained within twenty days, they were to become laws by the ſole authority of parliament. A ſtanding army for Great Britain and Ireland was eſtabliſhed, of 20,000 foot and 10,000 horſe; and funds were aſſigned for their ſupport. Theſe were not to be diminiſhed without the conſent of the protector; and in this article alone he aſſumed a negative. During the intervals of parliament, the protector and council had the power of enacting laws, which were to be valid till the next meeting of parliament. The chancellor, treaſurer, admiral, chief governors of Ireland and Scotland, and the chief juſtices of both the benches, muſt be choſen with the approbation of parliament; and in the intervals, with the approbation of the council, to be afterwards ratified by parliament. The protector was to enjoy his office during life; and on his death, the place was to be immediately ſupplied by the council. Such was the inſtrument of government enacted by the council of officers, and ſolemnly ſworn to by Oliver Cromwell. The council of ſtate, named by the inſtrument, conſiſted of 15 perſons; men entirely devoted to the protector, and by reaſon of the oppoſition among themſelves in party and principles, not likely ever to combine againſt him. The military force of the country was exerted under this government with vigour, conduct, and unanimity; and never did the kingdom appear more formidable to all foreign nations. In September, 1654, a new parliament was ſummoned. Of 400 members, which repreſented England, 270 were choſen by the counties; the reſt were elected by London, and the more conſiderable corporations; all the ſmall boroughs having been deprived of their right of election, becauſe they were the moſt expoſed to influence and corruption. The lower populace, ſo eaſily guided or deceived, were alſo excluded from the elections; an eſtate of 200*l.* value was neceſſary to entitle any one to a vote. The elections of this parliament, ſays Mr. Hume, were conducted with perfect freedom; and excepting, that part of the royaliſts which had borne arms againſt the parliament and all their ſons were excluded, a more fair repreſentation of the people could not be deſired or expected. Thirty members were returned from Scotland, and as many from Ireland. This parliament, having heard the protector's ſpeech of three hours length, and having choſen Lenthal for their ſpeaker, immediately entered into a diſcuſſion of the inſtrument of government, and of that authority, which Cromwell, by the title of protector, had aſſumed over the nation. The greateſt liberty was uſed in arraigning this new dignity; and even the perſonal character and conduct of Cromwell eſcaped not without cenſure. The protector, ſurpriſed and enraged at the refractory ſpirit of the parliament, ſent for them to the painted chamber, and authoritatively inveighed againſt their conduct. He obliged the members to ſign a recognition of his authority, and an engagement not to propoſe or conſent to any alteration in the government, as it was ſettled in a ſingle perſon and a parliament; and he placed guards at the door of the houſe, who allowed none but ſubſcribers to enter. Moſt of the members, after ſome heſitation, ſubmitted to this condition; but retained the ſame refractory ſpirit which they had manifeſted in their firſt debate. Cromwell haſtened to the diſſolution of this dangerous aſſembly, and having ordered their attendance, he delivered to them a tedious, confuſed, angry harangue, and diſmiſſed them.

In 1656, Cromwell, having gained to his adminiſtration ſo much luſtre and ſucceſs abroad, and [illegible] ſuch order and tranquillity at home, ventured to ſummon a parliament; having taken previous meaſures for filling the houſe with his own creatures and partiſans. He found, however, that the majority would not be favourable to him. He, therefore, ſet guards on the door, who permitted none to enter but ſuch as produced a warrant from his council: and the council rejected about a hundred, who either refuſed a recognition of the protector's government, or were on other accounts obnoxious to him. Theſe proteſted againſt a violence which was ſubverſive of all liberty; but every application for redreſs was neglected both by the council and parliament. In this parliament a motion was made to beſtow the crown on Cromwell; and no ſurpriſe or reluctance was diſcovered on the occaſion. A formal motion was afterwards made to the ſame purpoſe; but it produced great diſorder, and divided the houſe into parties. The bill was however voted by a conſiderable majority; and a committee was appointed to reaſon with the protector, and to overcome thoſe ſcruples which he pretended againſt accepting ſo liberal an offer. Cromwell's chief difficulty aroſe from the oppoſition of the ſoldiers; and he juſtly dreaded a mutiny in the army. At length he determined to decline the acceptance of that crown, which the repreſentatives of the nation, in the moſt ſolemn manner, had tendered to him. The parliament, when Cromwell had rejected the royal dignity, found themſelves obliged to retain the name of a commonwealth and protector; and as the government had hitherto been a manifeſt uſurpation, it was thought proper to ſanction it by a ſeeming choice of the people and their repreſentatives. Accordingly, inſtead of "the inſtrument of government," which was the work of the general officers alone, an "humble petition and advice" was framed, and offered to the protector by the parliament. This was repreſented as the great baſis of the republican eſtabliſhment, regulating and limiting the powers of each member of the conſtitution, and ſecuring the liberty of the people to the moſt remote poſterity. By this deed, the authority of protector was in ſome particulars enlarged; in others, it was conſiderably diminiſhed. He had the power of nominating his ſucceſſor; he had a perpetual revenue aſſigned him, of a million a year for the pay of the fleet and army, and 300,000*l.* for the ſupport of civil government; and he had authority to name another houſe, the members of which ſhould enjoy their ſeats during life, and exerciſe ſome functions of the former houſe of peers. But he abandoned the power aſſumed in the intervals of parliament, of framing laws with the conſent of his council; and he agreed, that no members of either houſe ſhould be excluded but by conſent of that houſe, of which they were members. The other articles were much the ſame with thoſe contained in the inſtrument of government. This model of government, the humble petition and advice, was accepted for the voluntary deed of the whole people in the three united nations; and Cromwell, as if his power had juſt commenced from this popular conſent, was anew inaugurated in Weſtminſter Hall, after the moſt ſolemn and pompous manner.

In 1658 the parliament was again aſſembled; conſiſting, as in the times of monarchy, of two houſes, the commons and the other houſe: Cromwell, during the interval having ſent writs to his houſe of peers, which conſiſted of 60 members. Upon the death of Cromwell in 1658 (ſee CROMWELL) the council recognized the ſucceſſion of his ſon Richard. A parliament was called; and in hopes of obtaining greater influence in elections, the ancient right was reſtored to all the ſmall boroughs; and the counties were allowed no more than their uſual members. The houſe of peers, or the other houſe, conſiſted of the ſame perſons that had been appointed by Oliver. All the commons, at firſt, ſigned an engagement, without heſitation, not to alter the preſent government; they next proceeded to examine "the humble petition and advice," and after much debate it was confirmed. But though parliament acquieſced, cabals were formed againſt the new protector by the army. Richard, who poſſeſſed neither penetration nor reſolution, was prevailed on to give an unguarded conſent for calling a general council of officers; but as ſoon as they were aſſembled, they voted a remonſtrance; and they propoſed that the whole military power ſhould be entruſted to ſome perſon, in whom they might all confide. The protector, who was in his diſpoſition gentle, humane, and generous, was juſtly alarmed at the movements of the officers; nor was the parliament leſs alarmed at the military cabals. They voted that there ſhould be no meeting or general council of officers, except with the protector's conſent, or by his orders. This enraged the officers, who haſtened to Richard, and demanded of him a diſſolution of the parliament. The parliament was diſſolved; and by the ſame act, the protector was, by every one, conſidered as dethroned. Soon after he ſigned his dimiſſion in form: and withdrawing into retirement, extended his peaceful life to an extreme old age. The council of officers, now poſſeſſed of ſupreme authority, deliberated what form of government they ſhould eſtabliſh. It was agreed at laſt to revive the long parliament, which had been expelled by Cromwell. The members of this parliament did not exceed 70; but they reſolved, ſince they enjoyed the title of the ſupreme authority, and obſerved that ſome appearance of a parliament was requiſite for the purpoſes of the army; not to act a ſubordinate part to thoſe who acknowledged themſelves as their ſervants. They choſe a council conſiſting of 7 perſons, who ſhould nominate to ſuch commands as became vacant; and they voted, that all commiſſions ſhould be received from the ſpeaker, and be aſſigned by him in the name of the houſe. The general officers were diſguſted by thoſe precautions; but the ſtate of the country prevented their manifeſting their diſguſt. As ſoon as an interval occurred, they renewed their hoſtility, and expelled the parliament. The officers, again poſſeſſed of ſupreme authority, elected a committee of 23 perſons, of whom 7 were officers, whom they pretended to inveſt with ſovereign authority; and they called them "the committee of ſafety." On the approach of danger, Lenthal the ſpeaker was invited by the officers to ſummon the parliament, which had twice before been expelled, with ſo much reproach and ignominy. But general Monk was advancing with his army, and having ſent a meſſage to the parliament from St. Alban's, deſiring them to remove from London thoſe regiments, which had ſo lately offered violence to their aſſembly; he marched towards London and took quarters at Weſtminſter. He afterwards required parliament, in the name of the citizens, ſoldiers, and whole commonwealth, to iſſue writs for the filling of their houſe, and to fix the time for their own diſſolution, and the aſſembling of a new parliament. The parliament attempted to conciliate the general, and diſpatched a committee to him for this purpoſe; but he refuſed to hear them, except in the preſence of ſome of the ſecluded members. Theſe members, upon the general's invitation, were reſtored; and the long parliament, after having paſſed ſome reſolutions for the compoſure of the kingdom, diſſolved itſelf, and iſſued writs for the immediate aſſembling of a new parliament. When the parliament met, meaſures were taken for the reſtoration of Charles II,; he was proclaimed in the preſence of the two houſes, on the 8th of May, and on the 29th, which was his birth-day, the king entered London. Rapin's Hiſt. vol. xi. Hume's Hiſt. vol. vii.

COMMORANCY, in *Law*, an abiding or dwelling in any place; as an inhabitant of an houſe in a vill, &c. Commorancy for a certain time may make a ſettlement in a pariſh. Commorancy conſiſts in uſually lying in a certain place. Dalt. Blackſt. Com. iv. 273.

COMMORTH, from the Brit. *Cymmorth*, q. d. ſubſidium, a contribution which was gathered at marriages, and when young prieſts ſaid or ſung the firſt maſſes, &c. See ſtat. 4 Hen. IV. c. 27. But ſtat. 26. Hen. VIII. c. 6, prohibits levying any ſuch in Wales, or the marches, &c. Cowel.

COMMOTAU, or Chomston, in *Geography*, a town of Bohemia, in the circle of Saatz. Large quantities of alum are prepared here. It is diſtant 10 miles N. W. of Saatz, 38 S. of Dreſden, and 42 N. W. of Prague.

COMMOTE, an ancient term in Wales, denoting half a cantred, or hundred; containing fifty villages. Stat. Walliæ, 12 Ed. I.

Wales was anciently divided into three provinces; each of theſe ſubdivided into cantreds; and every cantred into two *commotes*, or half hundreds.

Silveſter Girald, however, tells us, in his Itinerary, that a *commote* is but a quarter of a hundred. Commote alſo ſignifies a great ſigniory or lordſhip, and may include one, or divers manors. Co. Litt. 5.

COMMOTION, an inteſtine motion, or luctation in the parts of any thing.

In medicine, the term is chiefly uſed for a blow, or ſhake of the brain. A convulſion is a commotion of the fine medullary fibres of the brain. A fall occaſions a commotion, whence frequently ariſes a counterſtroke on the oppoſite part; which occaſions ſometimes a contrafiſſure, and at other times a rupture of the veſſels, and an impoſthume, by ſhaking the whole maſs of the brain.

COMMUNAM, *Appropriare*. See Appropriare, &c.

COMMUNANCE, a name formerly given to the commoners, or tenants and inhabitants, who had the right of common or commoning in an open field, &c. Cowley.

COMMUNE, in the preſent *organization* of France, denotes the ſubdiviſion of a canton, including ſometimes a ſingle town, and ſometimes an union of ſeveral villages, poſſeſſing a mayor, and a communal municipality. All the conſiderable cities are divided into ſeveral communes.

Commune *Concilium Regni Angliæ*, denotes the common council of the king and people aſſembled in parliament.

Commune *Rectum*. See Rectum.

COMMUNEM *Legem*, *Writ of Entry ad*. See Legem.

COMMUNIA *Placita non tenenda in ſcaccario*, an ancient writ directed to the treaſurer and barons of the Exchequer, forbidding them to hold plea between "common perſons," (*i. e.* not debtors, to the king, who alone originally ſued and were ſued there) in that court, where neither of the parties belong to the ſame. Reg. Orig. 187. But little obedience would be now paid to ſuch a writ, if any officers were to dare to iſſue it; for the court of Exchequer ſeems, by preſcription, to have attained a concurrent juriſdiction in civil ſuits with the other courts in Weſtminſter-hall.

COMMUNIBUS *Locis*, a Latin term, in frequent uſe among philoſophical, &c. writers; implying ſome medium, or mean relation between ſeveral places.

Dr. Keil ſuppoſes the ocean to be one quarter of a mile deep, *communibus locis*, *q. d.* at a medium, or taking one place with another.

Communibus *Annis*, has the ſame import with regard to years, that *communibus locis* has with regard to places.

Mr. Derham obſerves, that the depth of rain, *communibus annis*, *i. e.* one year with another, were it to ſtagnate on the earth, would amount to, at Townly in Lancaſhire, 42½ inches; at Upminſter, in Eſſex, 19¼; at Zurich, 32¼; at Piſa, 43¼; and at Paris, to 19 inches.

COMMUNICANS *Arteria Cerebri*, in *Anatomy*, is a branch of the internal carotid artery, which joins with a branch of the profunda cerebri, to form the circle of Willis. See Arteries.

COMMUNICATING, in *Theology*, the act of receiving the ſacrament of the Eucharist.

Thoſe of the *reformed*, and of the Greek church *communicate* under both kinds; thoſe of the Romiſh only under one.

The oriental communicants receive the ſpecies of wine by a ſpoon; and anciently they ſucked it through a pipe, as has been obſerved by Beat. Rheanus on Tertullian.

COMMUNICATION, the act of imparting a thing to another, or making him a ſharer with us therein.

The uſe of ſpeech is for the communicating of our ideas and ſentiments to each other.

Communication is alſo uſed for the connection of one thing with another; or the paſſage from one place to another. Anciently, it was frequent to have ſubterraneous communications between one place and another.

Communication, *Bridge of*. See Bridge.

Communication, in *Military Language*. Communications are all ſorts of ways or paſſages, above or below ground, which lead from different parts of the works to mines, or from one work to another. Thoſe are beſt, which cannot be annoyed by the enemy, but are ſecure againſt his fire. A place cannot be long or obſtinately defended without good communications; whereas, on the other hand, if theſe be good, it may hold out, if well garriſoned, and ſufficiently furniſhed with every thing neceſſary for defenſive operations, for a length of time. When its ditches are filled with water, or a river runs through it, floating bridges, boats, &c. ſerve as communications.

Communications *in and with a Camp*. In every camp there ſhould be communications between the different parts; and each of the principal, or more neceſſary ones, ought to be wide enough for forty or fifty men to walk abreaſt. As to communications with a camp, ſee the article Camp.

Communications *in the Attack of a Place*. Beſiegers ought to, and generally do, take care to join their works with one or ſeveral communications. All thoſe which they conſtruct in the parallels, on the glacis, and on the counterſcarp, communicate one with another. And as it generally happens, that the beſiegers' quarters in their camp are ſeparated by rivers, great or ſmall, or by marſhes, it is not only neceſſary, but of the firſt importance, to make cauſeways acroſs the marſhes and bridges of communication, acroſs the rivers, either on wooden frames, or on batteaux. It is better, however, to make them on frames or piles, if poſſible, as they are generally ſafer and ſtronger when ſo conſtructed, eſpecially if the place be in a ſituation to open a large ſluice of water capable of breaking thoſe placed on batteaux, as actually happened at the ſiege of Valenciennes, which the beſiegers were obliged to raiſe with loſs. That place was beſieged in 1656 by the French, under the command of the marſhals de Turenne and de la Ferté Senneterre. But the Spaniards, commanded by Don Juan of Auſtria, and the prince of Condé, made them raiſe the ſiege. And their quarters being ſeparated by the breaking of their bridges of communication, one half of their army was entirely routed, and the marſhal de la Ferté was made priſoner. In like manner, when the French were beſieging Turin with 72,000 men, prince Eugene, obſerving that one of their quarters was ſeparated from the reſt by rivers, and that their bridges were bad and neglected, attacked them in that place with 24,000 only, defeated them, and raiſed the ſiege.

The bridges ſhould be made very ſtrong and ſecure; and on every communication of difficulty or importance, there ſhould be at the leaſt four, at the diſtance of forty or fifty fathoms from one another. The avenues to them ought to be rendered as eaſy and practicable as poſſible. Guards ſhould be placed near them for their ſecurity, and to prevent their receiving any injury. And they ſhould always be made within the line of circumvallation, for the ſafety of thoſe who paſs and repaſs.

COMMUNICATION *of idioms*, in *Theology*, the act of imparting the attributes of one of the natures in Jeſus Chriſt to the other.

The communication of idioms is founded on the ſuppoſed union of two natures in the perſon of Chriſt: by this communication of idioms it is, that ſome divines ſay, God ſuffered, died, &c. which is ſtrictly underſtood of the human nature; and ſignifies that God ſuffered in his humanity, that he died as to his human nature, &c.

The Lutherans carry the communication of idioms ſo far, as to ſay, that Jeſus Chriſt is not only in his divine nature, and by reaſon of his divine perſon, but alſo really and properly in his humanity, immortal, immenſe, &c.

COMMUNICATION *of motion*, that act of a moving body, whereby another body at reſt is put by it in motion, or a body already in motion is accelerated.

F. Malebranche looks on the *communication of motion* as ſomething metaphyſical; *i. e.* as not neceſſarily ariſing from any phyſical principles, or any properties of bodies, but flowing from the immediate agency of God: there being, according to him, no more connection, or dependence, between the motion or reſt of one body, and that of another, than between the form, colour, magnitude, &c. of one body, and thoſe of another. The motion of one body, therefore, on his principle, is not any phyſical cauſe of that of another. See CAUSE.

The communication of motion reſults from, and is an evidence of the impenetrability and inertia of matter as ſuch: unleſs we admit the hypotheſis of penetrable matter, advanced by M. Boſcovich and Mr. Michell, and aſcribe to the powers of repulſion thoſe effects which have been uſually aſcribed to its ſolidity and actual reſiſtance. See MATTER.

Action, and re-action, ſir Iſaac Newton demonſtrates, are equal and oppoſite; ſo that one body ſtriking againſt another, and thereby occaſioning a change in its motion, does itſelf undergo the very ſame change in its own motion, the contrary way. See MOTION.

Hence, a moving body ſtriking directly againſt another at reſt, the one loſes juſt as much of its motion as it communicates to the other; and they will proceed with the ſame velocity as if united into one maſs. For the laws and quantity of motion ſo communicated, either in elaſtic or non elaſtic bodies; ſee COLLISION.

COMMUNICATION, *communicatio*, in *Rhetoric*. See ANACOINOSIS.

COMMUNI CUSTODIA, in *Law*, a writ which anciently lay for the lord, whoſe tenant holding by knight's ſervice died, and left his eldeſt ſon under age, againſt a ſtranger that entered the land, and obtained the ward of the body. F. N. B. 89. Reg. Orig. 161. Since the ſtat. 12. Car. II. c. 24., hath taken away wardſhips, this writ is of no uſe.

COMMUNION, in *Theology*, an uniform belief in ſeveral perſons; whereby they are united under one head, in one CHURCH. See UNITY, UNIFORMITY, &c.

In this ſenſe, the Lutherans, Calviniſts, &c. are ſaid to have been cut off from the Romiſh *communion*.

This is the primitive uſe of the word *communion*, as appears from the canons of the council of Elvira.

Though the term has been more extenſively applied to denote a general agreement in matters of doctrine, diſcipline, and worſhip. And unleſs the term be underſtood in this large ſenſe, ſo various are the opinions of men, there could be no *communion* among the members of any one church on earth.

COMMUNION is alſo uſed for the act of *communicating* in, or participating of, the ſacrament of the EUCHARIST. The fourth council of Lateran decrees, that every believer ſhall receive the communion, at leaſt, at Eaſter; which ſeems to import a tacit deſire, that they ſhould do it oftener; as, in effect they did it much oftner in the primitive days. Gratian, and the maſter of the ſentences, preſcribe it as rule for the laity to communicate three times a year, at Eaſter, Whitſuntide, and Chriſtmas. But in the thirteenth century, the practice was got on foot, never to approach the euchariſt except at Eaſter; and the council thought fit to enjoin it then by a law, leſt their coldneſs and remiſſneſs ſhould go farther ſtill.

And the council of Trent renewed the ſame injunction, and recommended frequent communion without enforcing it by an expreſs decree.

In the ninth century, the communion was ſtill received by the laity in both kinds; or, rather the ſpecies of bread was dipped in the wine, as is owned by the Romaniſts themſelves. Acta SS. Benedict Sæc. III. M. de Marca obſerves, that they received it at firſt in their hands, Hiſt. de Bern, and believes the communion under one kind alone to have had its riſe in the Weſt under pope Urban II. in 1096, at the time of the conqueſt of the Holy Land. And it was more ſolemnly enjoined by the council of Conſtance in 1414. The twenty-eighth canon of the council of Clermont enjoins the communion to be received under both kinds, diſtinctly; adding, however, two exceptions; the one of neceſſity, the other of caution, *niſi per neceſſitatem, & cautelam;* the firſt in favour of the ſick, the ſecond of the abſtemious, or thoſe who had an averſion from wine.

It was formerly a kind of canonical puniſhment, for clerks guilty of any crime, to be reduced to *lay communion*, i. e. only to receive as the laity did, *viz.* under one kind.

They had another puniſhment of the ſame nature, though under a different name, called *foreign communion;* to which the canons frequently condemned their biſhops, and other clerks. This puniſhment was not any excommunication, or depoſition; but a kind of ſuſpenſion from the function of the order; and a degradation from the rank they held in the church. It had its name becauſe the communion was only granted to the criminal on the foot of a foreign clerk, *i. e.* being reduced to the loweſt of his order, he took place after all thoſe of his rank, as all clerks, &c. did in the churches to which they did not belong. The ſecond council of Agda orders every clerk that abſents himſelf from the church, to be reduced to foreign communion.

COMMUNION, *Infant.* Some inſtances occur in the early ages of the church, of the practice of adminiſtering the euchariſt to infants: and ſome few have imitated this practice in more modern times. Mr. Pierce pleads the uſe of it even to this day among the Greeks, and in the Bohemian churches till near the time of the Reformation; and he refers to the uſage of the ancient churches, recorded by Photius, Auguſtin, and Cyprian. He urges from Scripture the right which children have to all the privileges of which they are capable, as well as the Jewiſh children under the law, who were allowed to eat of the paſſover, and other ſacrifices. To which it has been anſwered, that the ſacrifices, of which they were allowed to partake, were chiefly peace offerings, which became the common food of the family, and were not conſidered as acts of devotion in ſuch a degree as our euchariſt. He replies to the objection founded on the incapacity of infants to examine themſelves and diſcern the Lord's body, by obſerving that the precept extends only to thoſe who were capable of underſtanding and complying with it; on the ſame ground that faith is required previous to baptiſm. Biſhop Bedell ſuggeſts the following inquiry relative to this ſubject; what neceſſity of baptiſing infants, if their baptiſm produces no effect till they come to years of diſcretion? To which he replies, though the moſt principal effect be not attained preſently, the leſs principal are not to be refuſed: ſo children were circumciſed, who could not underſtand the reaſon of it, and the ſame alſo did eat the paſſover: and ſo did children baptized, in the primitive church, communicate in the Lord's ſupper: which I know not (ſays he) why it ſhould not be ſo ſtill; *de quo alias*. It has been alleged, that the foundation of this practice was a miſtaken apprehenſion of the abſolute neceſſity of this ordinance in order to ſalvation, reſulting from an erroneous interpretation of John vi. 53. See Biſhop Bedell's Letter to Dr. Ward, in p. 442 of Archbiſhop Uſher's Life by Parr. Pierce's Eſſay on the Euchariſt. Wall's Hiſt. of Infant Baptiſm, part ii. chap. 9. § 15 and 16. Waterland's Review of the Doctrine of the Euchariſt, and preface to his two volumes of Poſthumous Sermons, p. 32, &c. and Inquiry concerning Infant Communion, vol. ii. p. 75, &c.

COMMUNION *ſervice*, denotes that part of the liturgy of the church of England which relates to the adminiſtration of the ſacrament. See LITURGY.

COMMUNION-*table*. See ALTAR.

COMMUNIS CAPSULÆ. See CAPSULA.

COMMUNIS *ductus choledochus*. See DUCTUS.

COMMUNIS *digitorum manus extenſor*. See EXTENSOR.

COMMUNIS *labiorum depreſſor*. See DEPRESSOR.

COMMUNIS *labiorum elevator*. See ELEVATOR.

COMMUNIS *miſericordia*. See MISERICORDIA.

COMMUNITY, a ſociety or body of men united together under certain common laws, agreed on among themſelves, or impoſed by a ſuperior.

The Romans, who ſeem to have given the firſt hint of communities to the ſeveral nations into which their empire was divided, doubtleſs borrowed it from ſome rules of their neighbours: they call them *colleges;* which term, among them, had nearly the ſame ſignification with community among us. For an account of the introduction and eſtabliſhment of communities in Europe, ſee *Charters of* COMMUNITY and CITY. See alſo CORPORATION and CROISADE.

Communities now are of two kinds, *eccleſiaſtic* and *laic;* the firſt are either *ſecular*, as chapters of cathedral and collegiate churches; or *regular*, as convents, monaſteries, &c.

Lay communities are of various kinds; ſome contracted by a fixed abode of a year and a day in the ſame place; others formed by the diſcharge of the ſame office, the profeſſion of the ſame art, or attending the ſame place of worſhip, as thoſe of pariſhes, fraternities, &c.

Accordingly, the word is commonly underſtood of pious foundations for the ſupport of ſeveral perſons, either in a ſecular or regular life; as *colleges*, *abbies*, *convents*, *priories*, *ſeminaries*, *hoſpitals*, *inns*, &c.

Community is more particularly uſed in the French law, for the joint property in goods between the huſband and the wife: the reſult of which is, that during marriage they are equally intitled to all effects, and liable to all debts, contracted either before or under marriage.

Community is a ſpecies of ſucceſſion, and the acceptance of community reſembles an *additio hereditatis*.

Community was ſet on foot in favour of the wives, to enter them as ſharers in their huſband's effects.

In countries where the civil law obtains, this community has no place, nor even in ſeveral cuſtomary countries, as being reputed a burden on the man.

Anciently, the woman's ſhare in the community was only one-third; and this appears ſtill the ſenſe of the law among us, the widow, at the deceaſe of her huſband, being only intitled to one-third part of the moveables.

COMMUNITY, *continued*, in the *French Law*, is that which ſubſiſts between the ſurvivor of two perſons joined in marriage, and the minor children of that marriage, when the ſurvivor has not made an inventory of the effects in poſſeſſion during marriage. The widow may either renounce community with her children, or continue it.

COMMUNITY, *tacit*, is a community contracted between a man and woman, by the mere mingling of their effects, provided they have lived together the ſpace of a year and a day: this community, being odious, is now aboliſhed.

COMMUNITY, *Charters of*. See CHARTERS *of Community*.

COMMUNITY *of Goods*, as it has been ſometimes denominated, ſignifies a practice which was adopted for a ſhort time in the primitive church, and which conſiſted principally in a common uſe, derived from an unbounded liberality, that induced the opulent to ſhare their riches with their indigent brethren. The rich ſupplied the wants of their neceſſitous brethren with ſuch liberality and promptitude, that, as St. Luke tells us (Acts ii. 4. iv. 32.) among the primitive diſciples of Chriſt, all things were *in common*. This expreſſion, however, has been greatly abuſed, ſays Moſheim (E. H. v. i. p. 60), and has been made to ſignify a "community of rights, goods, and poſſeſſions," than which interpretation nothing is more groundleſs, nothing more falſe. From a multitude of reaſons, as well as from the expreſs words of St. Peter (Acts v. iv.) it evidently appears, that the community which is implied in mutual uſe, and mutual liberality, is the only thing intended in this paſſage. This is very clearly and ſatisfactorily proved by Moſheim, in a diſſertation concerning the true nature of the community of goods, which is ſaid to have taken place in the church of Jeruſalem. This learned diſcourſe is to be found in the ſecond volume of his excellent work entitled, "Diſſertationes ad Hiſtoriam eccleſiaſticam pertinentes." Mr. Gibbon (ſee Hiſt. Decl. and Fall of Rom. Emp. vol. ii. p. 341) has given a very uncandid and unjuſt ſtatement of this ancient Chriſtian practice, and inſtead of conſidering it as honourable to the liberality and mutual benevolence of the firſt diſciples, he ſeems to attach reproach and cenſure to it; when he ſuggeſts that the community of women, and that of temporal goods, may be conſidered as inſeparable parts of the ſame ſyſtem. He alſo obſerves that it was of the ſame kind with that which had ſo agreeably amuſed the imagination of Plato, and which ſubſiſted in ſome degree among the auſtere ſect of the Eſſenians; although it was undoubtedly of a very different nature. This author further adds, that the progreſs of the Chriſtian religion relaxed, and gradually aboliſhed this generous inſtitution, which, in hands leſs pure than thoſe of the apoſtles, would too ſoon have been corrupted and abuſed by the returning ſelfiſhneſs of human nature; and the converts who embraced the new religion were permitted to retain the poſſeſſion of their patrimony, to receive legacies and inheritances, and to increaſe their ſeparate property by all the lawful means of trade and induſtry. Biſhop Watſon (ſee his "Apology for Chriſtianity,") has juſtly obſerved, that the expreſſion "permitted to retain," in ordinary acceptation, implies an antecedent obligation to part with; but, as he adds, we have no account in ſcripture of any ſuch obligation being impoſed upon the converts to Chriſtianity, either by Chriſt himſelf, or by his apoſtles, or by any other authority: nay, in the very place where this community of goods is treated of, there is an expreſs proof to the contrary. When Peter was about to inflict an exemplary puniſhment upon Ananias (not for keeping back a part of the price, as ſome men are fond of repreſenting it, but) for his lying and hypocriſy, in offering a part of the price of his land as the whole of it; he ſaid to him, "Whilſt it remained (unſold) was it not thine own? and after it was ſold, was it not in thine own power?" From this account it is evident, that Ananias was under no obligation to part with his patrimony; and after he had parted with it, the price was in his own power; the apoſtle would have "permitted him to retain" the whole of it, if he had thought fit; though he would not permit his prevarication to go unpuniſhed.

Pythagoras not only taught his diſciples to be contented with a little, but even deprived them of all command over their own property, by caſting the poſſeſſions of each individual into a common ſtock, to be diſtributed by proper officers, as occaſion ſhould require. From the time of this ſequeſtration of their goods, as long as they continued members of this ſociety, they lived upon the footing of perfect equality, and ſat down together daily at a common table. If any one, however, repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution.

COMMUNITY *of the kingdom.* See **COMMONALTY**.

COMMUTATION, in *Aſtronomy*. *Angle of* **COMMUTATION**, is the diſtance between the ſun's true place ſeen from the earth, and the place of a planet reduced to the ecliptic. See **PLACE**.

Thus the angle ESR (*Plate* V. *Aſtronomy, fig.* 11.) ſubtended between the ſun's true place, E, viewed from the earth at S, and that of a planet reduced to the ecliptic, R, is the angle of commutation.

The angle of commutation, therefore, is found by ſubtracting the ſun's longitude from the heliocentric longitude of the planet R; or contrarily.

COMMUTATION, in *Law*, a change of a penalty, or puniſhment, *viz.* of a greater for a leſs, &c. as when death is commuted for, by baniſhment or perpetual impriſonment, &c. Suits are, and always were, allowable in the ſpiritual court, for money agreed to be given as a commutation for penance. Art. Cler. 9 Edw. II. c. 4. F. N. B. 53.

Some doubt whether the word be properly applied to any change but that of puniſhment: others will have it indifferently ſerve for the exchanging, or trucking of any thing.

COMMUTATION *Act*, an act paſſed during the ſeſſion of parliament in 1784, as part of a ſyſtem for the prevention of ſmuggling; ſo called becauſe, whilſt it gave up the exiſting duties and exciſe on teas, it propoſed an additional tax on windows, not as a new tax, but as a *commutation* for the portion of the duties on tea which it ſurrendered. The plan of the framers of this bill was to take off all the exciſe duty on tea, and impoſe a cuſtom duty of 12 *l.* 10 *s.* on Bohea tea, which, it was apprehended, would ruin the ſmuggling trade in that article. On the finer kinds of tea, a higher duty would be laid; 15 *l.* per cent. on ſouchong, &c.; 20 *l.* on ſinglo and hyſon; and 30 *l.* on congo. The total annual importation of teas into Europe amounted to about 19,000,000 *lbs.*, above two-thirds of which quantity were conſumed in Great Britain and Ireland, though the legal importation was not quite 6,000,000; conſequently the quantity annually ſmuggled muſt have been above 7,000,000 *lbs.* According to this calculation, the people of England were conſiderably under-rated at the number of 6,000,000. Of theſe it was ſaid that 2,000,000 would be relieved from the payment of the preſent duty on tea, without being obliged to contribute a farthing towards the tax which would be propoſed as a ſubſtitution; the other 4,000,000, it was calculated, would, one with another, conſume 3 *lbs.* of tea each in the year, for each pound of which, they, at this time, paid on an average 2 *s.* 7 *d.* duty; this duty, or the principal part of it being taken off, they could, of courſe, afford to pay a ſubſtituted tax, which was propoſed to be raiſed in the following manner:

On every houſe with ſeven windows, which houſe was alſo rated to the houſe tax, it was intended to lay an additional tax of 3 *s.* and ſo on, charging 8 *s.* for every houſe of eight windows; 9 *s.* for thoſe of nine windows; 10 *s.* 6 *d.* for thoſe of ten windows, and ſo on, adding 2 *s.* 6 *d.* for each window up to 24, and ſtill riſing up to 180 windows, for which 20 *l.* per annum ſhould be paid, over and above the duty at preſent paid on windows and houſes. This regulation was calculated to produce above 700,000 *l.*; ſo that with the new duty on tea, the produce would be near 900,000 *l.* It was ſuggeſted that, according to this plan, the public revenue would be a conſiderable gainer, and the people at the ſame time have no reaſon to complain of additional burdens. In England, Scotland, and Wales, it was calculated that there were about 699,058 houſes, which might be divided into the following claſſes; 286,293 houſes under ſeven windows; 211.483 houſes having from 8 to 10 windows; 38,324 of 11 windows; 24,919 from 12 to 13; 67,652, from 14 to 19; 52,652, of 20 windows and upwards; and 17,732 houſes in Scotland. Of theſe about 200,000 as being excuſed from the houſe-tax would pay nothing to this new tax, and the inhabitants being of the poorer ſort, would be wholly delivered from the duty on tea. This regulation, it was ſuppoſed, would check, or rather abſolutely ruin, the ſmuggling trade; beſides being productive of other benefits to the fair trader, and particularly to the Eaſt India Company. Againſt this bill, which, however, paſſed into a law, many objections have been urged. To the Eaſt India Company, it has been argued, this act enſured certain advantage; but thoſe which the public were to derive from it are leſs obvious and certain. It has been ſaid that thoſe houſholders who were to be charged with the new rate for windows were preciſely the perſons who ſhould have received the reciprocal benefit of the commutation: but that the reverſe of this is undoubtedly the caſe; they who do not pay the *new* window-tax, or indeed *any* window-tax at all, being the only perſons who ſhare among them any little advantages that have accrued from the agreement. The facts are theſe: Of the five different ſorts of teas conſumed by the public, there are *three* which are chiefly uſed by thoſe who pay the new window tax, *viz.* congo, ſouchong, and hyſon. The price of the two former of theſe (which are the moſt uſed of the three) has been ſo inconſiderably reduced, as to afford nothing like a pecuniary compenſation for the additional window-tax, and the price of the third ſort, hyſon, which is the deareſt and the leaſt uſed, though rather more reduced, is ſtill wholly diſproportionate to the promiſed commutation. The only two ſorts of tea, therefore, where the reduction of price is at all conſiderable, are bohea and ſinglo; and thoſe are in general conſumed by the lower orders of people only. From theſe facts it has been inferred, that they who pay the new tax conſume thoſe ſorts of tea, from which not *one-ſixth* of the propoſed ſaving ariſes; while they who do not pay any tax at all, or at moſt a ſmall portion of it, conſume thoſe ſpecies of tea upon which almoſt *the whole of the ſaving*, or at leaſt upwards of *five-ſixths* of it ariſes. The act has been deemed, by thoſe who ſtrenuouſly oppoſed it, unjuſt in its principle, and oppreſſive in its operation.

COMNENA, Anna, in *Biography*, daughter of the emperor Alexius Comnenus, flouriſhed about the year 1118, and wrote fifteen books upon the life and actions of her father, which ſhe called the "Alexiad." She has been accuſed of a too great partiality in favour of her hero, for which, conſidering her near relationſhip, ſhe may claim an indulgence. This work was publiſhed with a Latin tranſlation in 1661, and again in 1670; to this laſt edition are added notes hiſtorical and philological by the learned Du Freſne.

COMNENO, in *Geography*, a town of European Turkey, in the province of Albania; 36 miles S.E. of Albaſano.

COMO, Da, Fra. Emanuello, in *Biography*, ſo called from the place of his nativity, a conſiderable town in the ſtate of Milan, was an hiſtorical painter, whoſe taſte for the art was firſt called forth upon his ſeeing ſome painters at work in the cathedral of Como. Without the direction of any maſter, he afterwards attained ſome degree of eminence. His works, however, are of very unequal merit; he painted in the refectory of a convent at Como a "Laſt Supper," by which but an indifferent idea of his talents could be formed, were not his character retrieved by an excellent picture in the church repreſenting a Pieta with Sainto. He died aged 76, in the year 1701. Orlandi. Lanzi, Storia Pittorica.

Como, in *Geography*, a ſtrong, populous, and commercial town of Italy, and capital of a diſtrict in the Milaneſe, built by the Gauls, under the conduct of Brennus, ſituated at the ſouth end of a lake to which it gives name, in a plain, almoſt ſurrounded with mountains. The town is encompaſſed by a wall, guarded with pictureſque towers, and backed by a conical eminence, on which ſtand the ruins of an ancient wall. The houſes are almoſt wholly built of ſtone; and the cathedral is a handſome edifice of white marble, hewn from the neighbouring quarries. The inhabitants have eſtabliſhed ſeveral manufactures of cotton and ſilk, and carry on ſome trade with the Griſons. This town being diſtinguiſhed as the birth-place of Pliny the younger, his ſtatue is placed in a niche on the outſide of the church, and has a Latin inſcription bearing the date of 1499. It is diſtant 20 miles N. of Milan, in N. lat. 45° 44′. E. long. 8° 57′.

Como, *Lake of*, a lake of Italy in the Milaneſe, on the confines of Swiſſerland, about 32 miles long and 88 in circumference. At firſt it is ſcarcely a quarter of a mile broad, but it widens near a neck of land upon which is ſituated the ſmall village of Turnio. Towards the ſouth it is divided into two branches, at the end of one of which ſtands Como, and at the end of the other Lecco. The river Adda paſſes through it, and ſeveral country houſes and villages are ſituated on its banks, which are adorned with vines, cheſnuts, and almond-trees. The neighbourhood of Turnio, and the diſtricts bordering the lake of Como, ſupply, for the moſt part, thoſe Italian emigrants, who wander through Europe vending barometers and thermometers, of whom numbers annually reſort to England.

COMOCLADIA, in *Botany* (from Κομοω, *comatus ſum;* and Κλαδος, *ramus;* ſo called becauſe the branches have a tuft of leaves at the end, bearing a fancied reſemblance to a head of hair.) Linn. Gen. 49. Schreb. 66. Lam. Ill. 65. Willd. 82 Juſſ. 370. Vent. 3. 444. Claſs and order, *triandria monogynia.* Nat. Ord. *Terebintaceæ;* Juſſ. Vent.

Gen. Ch. *Calyx* one-leafed, three or four cleft, ſpreading, coloured; ſegments roundiſh. *Cor.* Petals three or four, roundiſh-egg-ſhaped, acute, flat, widely ſpreading, a little larger than the calyx. *Stam.* Filaments three or four, awl-ſhaped, ſhorter than the corolla; anthers roundiſh, incumbent. *Piſt.* Germ ſuperior, egg-ſhaped; ſtyle none; ſtigma obtuſe, ſimple. *Peric.* Drupe oblong, ſomewhat curved, marked at the top with three dots; nut membranous, the form of the drupe. *Seed* ſingle.

Eſſ. Ch. Calyx three, rarely four-cleft. Petals three or four. Drupe oblong; with one ſeed.

Sp. 1. C. *integrifolia.* Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Ill. 423. Willd. 1. Jacq. Amer. 12. Brown. Jam. 124. Lam. Ill. tab. 27. fig. 1. (Prunus racemoſa; Sloan. Jam. 2. 131. tab. 222. fig 1.) "Leaflets entire, ſmooth on both ſides." A tree, ſeldom more than twenty feet high. *Trunk* erect, of a moderate thickneſs; branches few, leafy at the end in open tufts. *Leaves* unequally winged, two feet long, leaflets not more than ſeventeen, four inches long, ovate-lanceolate, acuminate, ſlightly wrinkled by the tranſverſe veins, a little revolute at the edges. *Flowers* very numerous, ſmall, ſeſſile, without ſcent, of a deep red colour, in panicled racemes; racemes about twenty-four, a foot and a half long, branched, pendulous, always with a few quadrifid tetrandrous flowers intermixed with the others. A native of Jamaica, and St. Domingo. It abounds in a watery, ſlightly glutinous juice, which grows black when expoſed to the air, and ſtains the hands ſo as ſcarcely to be waſhed off. The wood is hard, of a fine grain, and reddiſh colour. 2. C *dentata.* Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. 425. Willd. 2. Jacq. Amer. 13. tab. 173. fig. 4. Pict. 12. tab. 259, fig. 2. "Leaflets egg-ſhaped, acute, toothed, ſomewhat prickly, veined and villous underneath." A tree much like the preceding. *Trunk* upright with few branches. *Leaves* a foot and half long, in tufts at the ends of the branches; leaflets from thirteen to twenty-one, oblong, acuminate, ſhining above, edged with prickly teeth. A native of Cuba. Its juice is milky, glutinous, turning very black in the air, durably ſtaining woollen and linen cloth, corroding the ſkin and rendering it ſcaly, ſmelling like liver of ſulphur, or the human excrement. The natives have an idea that to ſleep under it is dangerous. 3. C. *ilicifolia.* Swartz Prod. 17. Mart. 13. Lam. Ill. 424. Ill. tab. 27. fig. 2. (C. tricuſpidata; Nouv. Act. Acad. Paris, 1784, p. 347. Ilex dodonæa; Linn. Dodonæa; Plum. Gen. 20. tab. 118. fig. 1.) "Leaves roundiſh angular-ſpinous, ſmooth on both ſides." *Leaflets* ſeſſile, rigid, in crowded pairs terminated by an odd one. *Flowers* comparatively few; panicle very ſlender; racemes generally ſimple. A native of the Weſt Indies. La Marck's figure was taken from a dried ſpecimen. Willdenow has both an ilicifolia and an anguloſa, quoting for the latter La Marck's figure in oppoſition to La Marck himſelf. His error ſeems to have been occaſioned by miſtaking the ſynonym from Plumier, given by Linnæus, as a ſpineleſs variety of his ilex dodonæa, which Willdenow read D. aquifolii folio anguloſo *et* aculeato, inſtead of *non* aculeato, as it ſtands in the ſpecies plantarum.

Propagation and Culture.—The firſt two ſpecies have been propagated in England, by ſeeds obtained from their native climate. They require the ſame treatment as other tropical plants.

COMODI, Andrea, in *Biography*, an hiſtorical painter, who was born at Florence in 1560. He became at once the diſciple and companion of Ludovico Cigoli, and was ranked amongſt the beſt Florentine artiſts of his time, but the extreme difficulty which he found in ſatisfying himſelf with his own productions, has occaſioned their number to be very ſmall, conſidering the great age to which he lived. After having gone through the regular routine of academic ſtudy, he went to Rome, where he ſpent many years, and painted ſeveral freſcoes, particularly one in the tribuna of the church of St. Vitale, a compoſition of many figures, repreſenting Chriſt bearing his croſs, and on each ſide ſtories of martyrdoms. One of his moſt eſteemed eaſel pictures was a "Magdalen in the Deſert," for which the cardinal Barbarini preſented him with five hundred crowns, a very large price in thoſe times. His pictures of "Madonas" are very highly eſteemed for the beauty of their colouring and the delicacy with which they are finiſhed, and above all for an elegance and lightneſs of form, joined to an expreſſion of virgin modeſty peculiarly their own. His numerous copies of the pictures of Coreggio, and other great maſters are much eſteemed. He died in the year 1638. Baldinucci. Lanzi, Storia Pittorica.

COMOMBO, in *Geography*, or *the hill of Ombo*, anciently *Onebos*, a town of Egypt, ſituated to the ſouth of Thebes and on the ſame ſide of the river, where are ſtill ſeen conſiderable ruins of an ancient temple. The inhabitants of this place were famous for the worſhip of the crocodile, which they fed in their ponds (according to Ælian), where they became ſo tame, as to obey when they were called.

COMONAVA, a town of European Turkey, in the province of Macedonia; 60 miles N.N.E. of Akrida.

COMOPOLIS, in *Ancient Geography*, a town of Aſia, in Aſſyria, according to Ptolemy.—Alſo, a town of Aſia Minor, furnamed *Modrena*.—Alſo, a town of Aſia Minor, in Phrygia Salutaris, ſurnamed *Meros*; the ſame with *Myré*.

COMORA Isles, in *Geography*, are African iſlands in the Indian ocean, between the north-end of the iſland of Madagaſcar and the coaſt of Zanguebar, generally reckoned five in number, Johanna, Mayotta, Mohilla, Angazi, Comora, though ſome enumerate three, others four, and others eight, between the 41ſt and 46th degree of E. long. and the 10th and 14th of S. lat., at an equal diſtance from Madagaſcar and the continent of Africa. The largeſt is Johanna, which ſee. As the Comora iſles abound in horned cattle, ſheep, hogs, a variety of fruits and rice, they ſerve to refreſh the European ſhipping to and from India. The inhabitants are negroes of the Mahommedan religion; but they entertain the European ſeamen with great humanity.

Comora, one of the fore-mentioned iſlands, which gives name to the whole cluſter, about 6 leagues long, and three wide, but little known. S. lat. 11° 50′. E. long. 43°.

COMORIN, Cape, the ſouthernmoſt part of the ſouthern Hindooſtan, N.W. of the iſland of Ceylon. Though not above nine miles in extent, this promontory unites the two oppoſite ſeaſons of the year, owing to a ridge of mountains called the *Ghauts*, on the ſouth ſide of which trees are ſeen loaded with bloſſom and fruit, whilſt on the north ſide, the ſame ſort of trees are ſtripped of all their leaves. N. lat. 8°. E. long. 77° 32′ 30″.

COMORN, Comorra, Lat. a town of Hungary, and capital of a diſtrict, to which it gives name. It is ſo well defended by a fortreſs that the Turks could never take it. Its chief inhabitants were Hungarians, or Raſcians, who belong to the Greek church. In 1783 it was almoſt wholly deſtroyed by an earthquake: 36 miles S.E. of Preſburg, and 34 S.E. of Vienna.

COMORTH. See Commorth.

COMOSÆ, in *Botany*, the thirty-ſixth natural order in the Philoſophia Botanica of Linnæus, which he afterwards aboliſhed. It contained only ſpiræa, filipendula, and aruncus. Theſe are now all united in ſpiræa, and the genus referred to the order pomaceæ.

COMOSANDALOS, in *Antiquity*, a crown of flowers worn in the feſtival Chthonia.

COMOUCKS, in *Geography*, the Tartar inhabitants of Comania or Dagheſtan in Aſia, under the protection of Perſia. They are ferocious robbers. Every town has a chief named *Myrſa*; and the head of thoſe chiefs choſen from among themſelves is called *Schmkal*.

COMPACH, a river of Carinthia, which runs into the Moll, near Vellach.

COMPACT, in *Phyſics*, is a relative term, denoting a body to be cloſe, denſe, and heavy; having few pores, and thoſe ſmall ones. The heavieſt metals, as gold and ſilver, are the moſt *compact*. See Gravity.

Compact, in a *Legal Senſe*, ſignifies an agreement, or a contract, ſtipulated between ſeveral parties. A compact carries with it an obligation equal in point of conſcience to that of a law; but the original of the obligation is different. In compacts, we ourſelves determine and promiſe what ſhall be done, before we are obliged to do it; whereas in laws, we are obliged to act without ourſelves determining or promiſing at all. See Contract.

Compact is alſo the name of a celebrated bull, confirmed by pope Paul IV. relating to the cardinals.

In virtue of the bull of *compacts*, cardinals can only confer benefices in their natural ſtate; i.e. regular benefices on regulars.

COMPAGES *circularis montium*, a term deviſed by Kircher to expreſs what he in other places calls the annularity, or annular diſpoſition of Mountains, which he ſays run in continued chains, forming belts or ridges in the manner of ſpines, all round the globe of the earth, from north to ſouth, and ſo on from that point to north again, and in the ſame manner from eaſt to weſt, and from weſt to eaſt again.

COMPAGNE, Fr. The cabin of the commander or chief of a galley.

COMPAGNIES *aux Gardes*. Theſe were the companies of infantry that compoſed the regiment of French guards, making part of the houſehold troops of the king for the exterior guard. And it was uſual to ſay *Capitaine aux Gardes*, *Lieutenant aux Gardes*, &c.

Compagnie *Ecoſſoiſe*. See Gendarmerie or *Gardes du Corps*.

Compagnies *d'Ordonnance*. Theſe were companies that never formed corps or regiments, like the *gendarmes*, the light horſe, the muſketeers, &c.

Compagnies *des Gardes*. The four companies of horſe-guards made part of the troops of the houſehold of the kings of France for the interior guard. Thus, in ſpeaking of that corps, it was uſual to ſay, a captain of the guards, a lieutenant of the guards, &c. It was cuſtomary to ſpeak in the ſame manner of Swiſs guards.

Compagnies *Franches*, Fr. Theſe free companies were not regimented, but in time of war were put on a certain eſtabliſhment. Each of them had a chief, who commanded it. They were generally compoſed of dragoons, huſſars, and foot ſoldiers. All thoſe who ſerved in theſe corps or companies were called *partiſans*. They were employed in making incurſions into the enemy's country, and laying it waſte as much as they could. An officer, who had ſerved ſome campaigns as a partiſan, could not eaſily afterwards ſerve with regular troops. They are a ſort of voluntary pirates, who know no kind of ſubordination but that which is peculiar to themſelves. When theſe troops have chiefs that are hardy, brave, and intelligent, they render important ſervices to armies.

Compagnie *du Guet a pied.* See the article Maréchauſſée.

Compagnie *du Lieutenant criminel de Robecourte.* See alſo the article Maréchauſſée.

Compagnie *d'Ordonnance a cheval.* See the ſame article.

Independent company is one that is not incorporated into a regiment. Two ſuch companies generally belong to each regiment in England, for the purpoſe of ſupplying the regiments with recruits.

COMPAGUS, in *Antiquity,* a kind of ſummer-ſhoe worn by the Roman ſenators, conſiſting only of a ſole at the bottom; it was faſtened with leathern ſtraps, croſſing one another many times about the leg.

Rubenius makes the *compagi* to have been a ſort of caligæ worn by the roman generals as well as ſenators. Under the later emperors, in the middle age, we read of the ſame worn by popes, biſhops, and abbots.

COMPANION *of the Garter,* an appellation diſtinguiſhing one of the knights of that moſt noble order, at the head of which is the king, as ſovereign. Stat. 24 Hen. VIII. c. 13. See Garter.

COMPANY, a collective term, underſtood of ſeveral perſons aſſembled together in the ſame place, or with the ſame deſign. See Society.

The word is formed of the French *compagnie,* and that of *companio* or *companies,* which, Chifflet obſerves, are found in the Salic law, tit. 66. and are properly military words, underſtood of ſoldiers, who, according to the modern phraſe, are comrades, or meſs-mates, i. e. lodge together, eat together, &c. of the Latin *cum, with,* and *panis, bread.* It may be added, that in ſome Greek authors under the Weſtern empire, the word κυμπανια occurs in the ſenſe of *ſociety.*

Company, in *Commerce,* is an aſſociation of ſeveral merchants, or others, who unite in one common intereſt, and contribute by their ſtock, their counſel, and ſtudy, to the ſetting on foot, or ſupporting, of ſome lucrative eſtabliſhment.

Though *company* and ſociety, or fellowſhip, be in effect, the ſame thing, yet cuſtom has made a difference between them; ſociety, or partnerſhip, being underſtood of two, or three dealers, or not many more; and *company* uſually of a greater number. See Society.

A ſecond difference between *companies* and ſocieties is, that the firſt, eſpecially when they have excluſive privileges, cannot be eſtabliſhed without the conceſſion of the prince; and need letters patent, charters, &c. Whereas, for the latter, the conſent of the members, fixed and certified by acts and contracts, and authorized by bye-laws, is ſufficient.

The ſeveral profeſſions and trades exerciſed in the city of London, being incorporated into diſtinct fraternities, governed by their particular laws, a tabular view of them may not be unacceptable.

The abſtract of their incorporations, and particular privileges, is taken from the records of the Tower, &c. and from the Firma-Burgi of Madox, the king's hiſtoriographer; the account of their charities from thoſe eminent hiſtorians Stow and Strype; and the fines of the liverymen on admiſſion, are taken from the returns to the clerk of the parliament, and the ſcrutiny-books made after the ſeveral polls for the magiſtrates and repreſentatives of the city.

The companies are here placed according to their prececedence, beginning with the twelve principal ones, of one or other of which the lord mayors have generally made themſelves free at their election, if they were not ſo before; for they are not only the oldeſt, but the richeſt, many of them having had the honour of kings and princes to be their members, and the apartments of their halls being fit to entertain a monarch.

Companies.	Halls.	Incorporated by	A. D.	Livery fines			Charitable Gifts paid yearly, and Privileges, &c.	
				l.	*s.*	*d.*	*l.*	
1 Mercers	Cheapſide	Richard II.	1393	2	13	4	3000	Excluſive of 20 per cent. paid yearly to the widows of ſubſcribing clergymen during life, purſuant to a propoſal accepted in 1698, when they ſettled a fund of 14,000*l.* a year for that purpoſe.
2 Grocers	Poultry, Groc. alley	Edward III.	1345	20	0	0	700	
3 Drapers	Throgmorton ſtreet	Henry VI.	1439	25	0	0	4000	
4 Fiſhmongers	Thames-ſtreet	Henry VIII.	1536	13	6	8	800	
5 Goldſmiths	Foſter-lane	Richard II.	1393	20	0	0	1000	They had a privilege from Ed. IV. to inſpect, try, and regulate all gold and ſilver wares throughout the kingdom, and to puniſh all workers in either that was adulterated.
6 Skinners	Dowgate-hill	Edward III.	1327	15	0	0	700	
7 Merchant Taylors	Threadneedle-ſtreet	Edward IV.	1466	20	0	0	2000	They were once ſtyled taylors and linen armourers.
8 Haberdaſhers	Maiden-lane	Henry VI.	1447	25	0	0	3500	Were anciently ſtyled Milaners, becauſe they dealt in moſt that came from Milan.
9 Salters	Swithin's-lane	Q. Elizabeth	1558	20	0	0	500	
10 Ironmongers	Fenchurch-ſtreet	Edward IV.	1464	31	10	0	1800	In 1724, Mr Betton, a Turkey merchant, left 26,000*l.* in truſt; one moiety of the profits of it to be always applied to the ranſom of Britiſh captives from Mooriſh ſlavery; the other for the poor of the company, and to the charity-ſchools in its city and its liberty.
11 Vintners	Thames-ſtreet	Henry VI.	1437	31	13	4	600	
12 Clothworkers	Mincing-lane	Edward IV.	1482	31	10	0	1400

					l.	s.	d.	l.
13	Dyers	Elbow-lane	Edward IV.	1472	15	0	0	
14	Brewers	Addle ſtreet	Henry VI.	1438	6	13	4	
15	Leatherſellers *	Little St. Helens	Henry VI.	1442	20	0	0	* Hen. VII. made their wardens inſpectors of ſheep, lamb, and calves leather throughout the kingdom.
16	Pewterers ‡	Lime-ſtreet	Edward IV.	1474	20	0	0	‡ By act of Parl. 25 Hen. VIII. their wardens had the inſpection of pewter throughout England.
17	Barber-ſurgeons †	Monkwell-ſtreet	Edward IV.	1461	10	0	0	† In the reign of Hen. VIII. the ſurgeons of this company, then but 19, were exempted by parliament from ward and pariſh offices, and from military ſervice. They were incorporated ſeparately by 18 Geo. II. cap. 15. and the company of ſurgeons had an elegant hall in the Old Bailey, with a theatre for the diſſection of human bodies. They now form a royal college, and their houſe is in Lincoln's Inn fields.
18	Cutlers	Cloak-lane	Henry V.	1417	10	0	0	
19	Bakers	Harp-lane	Edward II.	1307	10	0	0	
20	Wax-chandlers	Maiden-lane	Richard III.	1483	5	0	0	
21	Tallow-chandlers	Dowgate-hill	Edward IV.	1463	15	0	0	
22	Armourers §	Coleman-ſtreet	Henry VI.	1423	15	0	0	§ The braſiers are united to this company.
23	Girdlers ‖	Baſinghall-ſtreet	Henry VI.	1449	5	0	0	‖ Q. Elizabeth incorporated the pinners and wire-drawers with them.
24	Butchers †	Pudding-lane	James I.	1615	11	11	0	† This is an ancient fraternity; of which we have an account in the reign of Henry II. A. D. 1180.
25	Sadlers	Cheapſide	Edward I.		10	0	0	
26	Carpenters	London-wall	Edward III.	1344	8	0	0	
27	Cordwainers	Diſtaff-lane	Henry IV.	1410	10	0	0	
28	Painter-ſtainers	Little Trinity-lane	Q. Elizabeth	1582	14	0	0	
29	Curriers	Near Cripplegate	James I.	1605	9	13	4	
30	Maſons	Baſinghall-ſtreet	Charles II.	1677	5	0	0	
31	Plumbers	Near Dowgate-hill	James I.	1611	10	0	0	
32	Innholders	Elbow-lane	Henry VIII.	1515	10	0	0	
33	Founders **	Lothbury	James I.	1614	8	0	0	** All braſs weights made in London, or three miles from it, muſt be ſized with the company's ſtandard, and have their mark; the averdupois to be ſealed at Guildhall, and the troy at goldſmith's hall. And the company are empowered by charter, to view and ſearch all braſs weights, and braſs and copper wares made within the ſaid diſtrict.
34	Poulters	No hall	Henry VII.	1504	10	0	0	
35	Cooks	Hall burnt	Edward IV.	1480	10	0	0	
36	Coopers	Baſinghall-ſtreet	Henry VII.	1501	15	0	0	
37	Tylers and bricklayers	Leadenhall-ſtreet	Q. Elizabeth	1568	12	0	0	
38	Bowyers	No hall	James I.	1620	8	0	0	
39	Fletchers ¶	St. Mary Axe	No charter		10	0	0	¶ It is only a company by preſcription.
40	Blackſmiths	Lambeth-hill	Q. Elizabeth	1577	8	0	0	
41	Joyners and cielers	Thames-ſtreet	Q. Elizabeth	1569	8	0	0	
42	Weavers	Baſinghall-ſtreet	Henry II.		6	0	0	
43	Woolmen	No hall	No charter					No livery; but they have a maſter, 2 wardens, and 11 aſſiſtants. They are only a company by preſcription, yet ſuppoſed to have commenced with the wool-trade.
44	Scriveners	No hall	James I.	1616	5	0	0	
45	Fruiterers	No hall	James I.	1605	5	0	0	
46	Plaiſterers	Addle ſtreet	Henry VII.	1501	8	0	0	
47	Stationers ††	Ludgate-ſtreet	Philip & Mary	1557	20	0	0	†† This company, which alſo includes bookſellers, letter-founders, printers, and book-binders, have a ſtock which is employed in printing almanacks, primers, pſalters, ſchool-books, &c. of which they have the ſole privilege, by virtue of a grant from the crown. This ſtock conſiſts of ſhares, which are diſtributed in different proportions among thoſe who have fined for, or ſerved the office of renter-wardens: whoſe ſhares, if they die married, devolve to their widows. They pay above 200l. a year in penſions and other charities. They are likewiſe truſtees for the diſpoſal of the conſiderable legacies of Mr. William Bowyer, a learned printer, (who died Nov. 18, 1778) conſiſting of 30 l. a year to the moſt learned journeyman that can be met with; and 180 l. a year in annuities of 20 l. each to nine neceſſitous printers of ſixty-three years of age or upwards; beſides other charities.
48	Broderers	Gutter-lane	Q. Elizabeth	1591	5	0	0	
49	Upholders	No hall	Charles I.	1627	4	10	0	
50	Muſicians	No hall	James I.	1604	10	0	0	

	Companies.	Halls.	Incorporated by	A. D.	Livery fines. *l. s. d.*	Charitable Gifts, paid yearly, and Privileges, &c.
51	Turners	College-hill	James I.	1604	8 0 0	
52	Baſket-makers	No hall	No charter		No livery; yet a company by preſcription, governed by 2 wardens and 48 aſſiſtants, with this motto to its arms, *Let us love one another.*	
53	Glaſiers ‖	No hall	Charles I.	1637	3 0 0	‖ The glaſs painters are incorporated with them.
54	Horners	No hall	Charles I.	1638	No livery; yet they have a maſter, 2 wardens, and 9 aſſiſtants, with a warehouſe in Spitalfields; where they divide in lots, among themſelves, ſuch horns as are bought up by their members in Leadenhall and other markets: And in 1465, they obtained an act of parliament that none ſhould be exported, but ſuch as they refuſed.	
55	Farriers	No hall	Charles II.	1673	5 0 0	
56	Paviours	No hall	No charter		No livery; yet it is a fellowſhip by preſcription, with 3 wardens, and 25 aſſiſtants.	
57	Loriners	London-wall	Q. Anne	1712	10 0 0	
58	Apothecaries	Blackfryars	James I.	1617	16 0 0	They are exempt from ward and pariſh-offices, and have a ſpacious phyſic-garden at Chelſea; which in 1721 was granted to the company for ever by Sir Hans Sloane, bart. the lord of the manor, on condition of their paying a quit-rent of 5 *l.* and continuing it always as a phyſic-garden, and of preſenting every year to the Royal Society fifty ſamples of different ſorts of plants, there grown, till they amount to two thouſand.—The latter of theſe conditions hath been long ſince more than completed. This is what may be called a trading company.
59	Shipwrights	No hall	James I.	1605	No livery; yet they have a maſter, 2 wardens, and 16 aſſiſtants.	
60	Spectacle-makers	No hall	Charles I.		No livery; yet have a maſter, 2 wardens, and 15 aſſiſtants.	
61	Clock-makers	No hall	Charles I.	1632	10 0 0	
62	Glovers	No hall	Charles I.	1638	5 17 4	
63	Comb-makers	No hall	Charles I.	1636	No livery; yet they have a maſter, 2 wardens, and 13 aſſiſtants.	
64	Felt-makers	No hall	James I.	1604	5 0 0	
65	Framework-knitters	Red croſs-ſtreet	Charles II.	1663	10 0 0	
66	Silk-throwers	No hall	Charles I.	1630	No livery; yet have a maſter, 2 wardens, and 20 aſſiſtants.	
67	Silkmen	No hall	Charles I.	1631	No livery; yet have a governor, and 20 aſſiſtants.	
68	Carmen, have no hall, nor charter, nor livery; but are a fellowſhip by act of common council, with the title of Free Carmen of the city of London, and have a maſter, 2 wardens, and 41 aſſiſtants, under the direction of the lord mayor and aldermen. The carts that belong to this fellowſhip, which are betwixt 4 and 500, are, by an act of common council, ſubjected to the rule of the preſident and governors of Chriſt's Hoſpital; to whom the owner of every cart pays 17 *s.* 4 *d.* a year for a licence to work it, and every cart is brought to the hoſpital to have a number in braſs put upon it.					
69	Pin-makers	No hall	Charles I.	1636	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
70	Needle-makers	No hall	O. Cromwell	1656	5 5 0	
71	Gardeners	No hall	James I.	1616	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
72	Soap makers	No hall	Charles I.	1630	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
73	Tin-plate-workers	No hall	Charles II.	1670	10 0 0	
74	Wheelwrights	No hall	Charles II.	1670	15 15 0	
75	Diſtillers	No hall	Charles I.	1638	13 6 8	
76	Hatband-makers	No hall	Charles I.	1638	Incorporated with the company of needle-makers.	
77	Patten-makers	No hall	Charles II.	1670	6 0 0	
78	Glaſs-ſellers and looking-glaſs-makers	No hall	Charles II.	1664	5 0 0	
79	Tobacco-pipe-makers	No hall	Charles II	1663	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
80	Coach and harneſs-makers	Noble-ſtreet	Charles II.	1677	10 0 0	
81	Gunſmiths	No hall	Charles I.	1638	10 0 0	
82	Gold and ſilver wire-drawers	No hall	James I.	1623	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
83	Long-bow-ſtring-makers	No hall	No charter		No livery; yet a company by preſcription, and have 2 wardens, and 19 aſſiſtants.	

	Companies.	Halls.	Inorporated by	A. D.	Livery fines.	Charitable Gifts paid yearly, and Privileges, &c.
84	Card-makers	No hall	Charles I.	1629	No livery; yet have a maſter, 2 wardens, and 18 aſſiſtants.	
85	Fan-makers	No hall	Q. Anne	1709	No livery; yet have a maſter, 2 wardens, and 20 aſſiſtants.	

86 Woodmongers were a company incorporated with the carmen by K. James I. 1605, but ſurrendered their charter in 1668; by an act of common council in 1694, they obtained a privilege of keeping 120 carts, excluſive of the number kept by the carmen, *extinct*.

87	Starch-makers, *extinct*	No hall	James I.	1622	
88	Fiſhermen, *extinct*	No hall	James II.	1687	
89	Pariſh-clerks	Wood-ſtreet	Henry III.	1233	By a decree of the Star chamber court in 1625, they obtained a privilege to keep a preſs in their hall, for printing the weekly bills of mortality, by a perſon appointed by the archbiſhop of Canterbury. They are, by their charter, to make a report of all the weekly chriſtenings and burials in their ſeveral pariſhes every Tueſday, and they have a maſter, 2 wardens, and 17 aſſiſtants.

90 Porters, are another fellowſhip, without hall, or livery; conſiſting of tackle and ticket-porters. They were conſtituted a fraternity by act of common council in 1646, with a power of annually chuſing among themſelves twelve rulers, being ſix of each denomination. However, the court of lord mayor and aldermen have reſerved to themſelves a power of appointing one of their own body, as the chief judge in all controverſies. One very laudable cuſtom of the maſter tackle-porters is, that ſuch of their brethren as happen to be diſabled from working, receive their ſhare of all profits, as if actually in buſineſs, during life.

91 The watermen, wherrymen, and lightermen of this city and neighbouring places, were by act of K. William III. conſtituted a ſociety, or company, under the direction of the lord mayor and aldermen. They are to furniſh 1000 men for the navy, upon demand by the admiralty. They have a hall at Coal Harbour, near the Thames; and pay to their poor about 800 *l.* a year; chiefly raiſed by ferries over the Thames on Sunday.

N. B. The company of Surgeons, Pariſh-clerks, Porters and Watermen, have not the privilege of making their members freemen of the city of London.

From the foregoing liſt, it appears on the whole, that there are ninety-one companies, forty-eight halls, and that the number of liverymen, according to the moſt exact account that could be procured, in 1779, was 8954, but this number is variable. The ſums of money yearly diſtributed in charity by only twenty-three of the companies, amounts to more than 23,655 *l.*; and if but fortypounds each be annually given by the remaining ſixty-eight companies, the whole will much exceed 26,375*l.* per annum.

Company ſeems more peculiarly appropriated to thoſe grand aſſociations, ſet on foot for the commerce of the remote parts of the world; as the Engliſh and Dutch Eaſt India company, South Sea company, Miſſiſſippi company, &c.; the riſe and eſtabliſhment of which, we ſhall here ſet before the reader.

However injurious companies with joint-ſtock, and incorporated with excluſive privileges, may, at this time, be reckoned to the nation in general; it is yet certain that they were the general parent of all our foreign commerce: private traders being diſcouraged from hazarding their fortunes in foreign commerce, until the method of traffic had been firſt ſettled by joint-ſtock companies. From this principle it is, that we find ſeveral nations that are now endeavouring to improve their trade, and to eſtabliſh or increaſe marine power, by the means of joint-ſtock companies.

But ſince the trade of this kingdom, and the number of traders have increaſed, and the methods of aſſurance of ſhipping and merchandiſe, and the navigation to all parts of the known world have become familiar to us; theſe companies, in the opinions of moſt men, have been looked upon in the light of monopolies: their privileges have therefore been leſſened from time to time, in order to favour a free and general trade; and experience has ſhewn, that the trade of the nation has advanced, in proportion as monopolies have been diſcouraged. When companies do not trade upon a joint-ſtock, but are obliged to admit any perſon properly qualified, upon paying a certain fine, and agreeing to ſubmit to the regulations of the company, each member trading upon his own ſtock, and at his own riſk, they are called *regulated companies*. When they trade upon a joint-ſtock, each member ſharing in the common profit or loſs in proportion to his ſhare in this ſtock, they are called *joint-ſtock companies*. Such companies, whether regulated or joint-ſtock, ſometimes have, and ſometimes have not, excluſive privileges. Regulated companies reſemble, in every reſpect, the corporations of trades, ſo common in the cities and towns of all the different countries of Europe; and are a ſort of enlarged monopolies of the ſame kind. As no inhabitant of a town can exerciſe an incorporated trade, without firſt obtaining his freedom in the corporation; ſo in moſt caſes no ſubject of the ſtate can lawfully carry on any branch of foreign trade, for which a regulated company is eſtabliſhed, without firſt becoming a member of that company. Of companies of this kind we have had, or ſtill have, in Great Britain, the Hamburgh company, the Ruſſia company, the Eaſtland company, the Turkey company, and the African company. Regulated companies, as ſir Joſhua Child has obſerved, though they had frequently ſupported public miniſters, had never maintained any forts or garriſons in the countries to which they traded; whereas joint-ſtock companies frequently had. And in reality, ſays Dr. Smith, (Wealth of Nations, vol. iii. p. 116.) the former ſeem to be much more unfit for this ſort of ſervice than the latter; partly, becauſe the directors of a regulated company have no particular intereſt in the proſperity of the general trade of the country, for the ſake of which ſuch forts and garriſons are maintained; whereas the private intereſt of the directors of a joint-ſtock company, is connected with the proſperity of the general trade of the company, and with the maintenance of the forts and garriſons which are neceſſary for its defence; and partly, becauſe the directors of the latter company have always the management of a large capital, the joint-ſtock of the company, a part of which they may frequently employ, with propriety, in building, repairing, and maintaining ſuch neceſſary forts and garriſons; whilſt the directors of a regulated company, having the management of no common capital, have no other fund to employ in this way, but the caſual revenue ariſing from the admiſſion fines, and from the corporation duties impoſed upon the trade of the company.

Joint-ſtock companies, eſtabliſhed either by royal charter or by act of parliament, differ, in ſeveral reſpects, not only from regulated companies, but from private copartneries. 1ſt. In a private copartnery, no partner, without the conſent of the company, can transfer his ſhare to another perſon, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnery, and demand payment of his ſhare of the common ſtock. In a joint-ſtock company, on the contrary, no member can demand payment of his ſhare from the company; but each member can, without their conſent, transfer his ſhare to another perſon, and thereby introduce a new member. 2dly. In a private copartnery, each partner is bound for the debts contracted by the company to the whole extent of his fortune; whereas, in a joint-ſtock company, each partner is bound only to the extent of his ſhare. The trade of a joint-ſtock company is always managed by a court of directors, which is frequently ſubject, in a variety of reſpects, to the controul of a general court of proprietors; but theſe proprietors, being for the moſt part totally exempted from trouble and from riſk, beyond a limited ſum, receive contentedly ſuch half-yearly or yearly dividends, as the directors think proper to aſſign; and many perſons are encouraged to become adventurers in joint-ſtock companies, who would, upon no account, hazard their fortunes in any private copartnery. The directors of ſuch companies being the managers rather of other people's money than of their own, it cannot well be expected, that they ſhould watch over it with the ſame anxious vigilance with which the partners in a private copartnery frequently watch over their own. Negligence and profuſion muſt always prevail, more or leſs, in the management of the affairs of ſuch a company. It is upon this account that joint-ſtock companies for foreign trade have ſeldom been able to maintain the competition againſt private adventurers. They have, accordingly, very ſeldom ſucceeded without an excluſive privilege, and frequently have not ſucceeded with one. Without an excluſive privilege, they have commonly miſmanaged the trade; with an excluſive privilege, they have both miſmanaged and confined it. For other appropriate and juſt obſervations on this ſubject, in its reference to the African company, the Hudſon's bay company, the South Sea company, and the Eaſt India company, ſee Smith's Wealth of Nations, vol. iii. chap. 1.

When a company of merchants undertake, at their own riſk and expence, to eſtabliſh a new trade with ſome remote and barbarous nation, it may not be unreaſonable to incorporate them into a joint-ſtock company, and to grant them, in caſe of their ſucceſs, a monopoly of the trade for a certain number of years. It is the ancient and moſt natural way in which the ſtate can recompenſe them for hazarding a dangerous and expenſive experiment, of which the public is afterwards to reap the benefit. A temporary monopoly of this kind may be vindicated upon the ſame principles upon which a like monopoly of a new machine is granted to its inventor, and that of a new book to its author. But upon the expiration of this term, the monopoly ought certainly to terminate; the forts and garriſons, if it was found neceſſary to eſtabliſh any, to be taken into the hands of government, their value to be paid to the company, and the trade to be laid open to all the ſubjects of the ſtate. Without a monopoly, however, a joint-ſtock company, as experience has ſhewn, cannot carry on any branch of foreign trade. An eminent French author, of great knowledge in matters of political economy, the abbé Morellet, gives a liſt of 55 joint-ſtock companies for foreign trade, which have been eſtabliſhed in different parts of Europe ſince the year 1600, and which, according to him, have all failed from miſmanagement, notwithſtanding they had excluſive privileges. Although he has been miſinformed with regard to the hiſtory of two or three of them, which were not joint-ſtock companies, and which have not failed; yet there have been ſeveral joint-ſtock companies, which have failed, and which he has omitted.

The only trades which it ſeems poſſible for a joint-ſtock company to carry on ſucceſsfully without an excluſive privilege, are thoſe, of which all the operations are capable of being reduced to what is called a routine, or to ſuch an uniformity of method as admits of little or no variation. Of this kind is, firſt, the banking trade; ſecondly, the trade of inſurance from fire, and from ſea-riſk and capture in time of war; thirdly, the trade of making and maintaining a navigable cut or canal; and fourthly, the ſimilar trade of bringing water for the ſupply of a great city. To render the eſtabliſhment of a joint-ſtock company perfectly reaſonable, with the circumſtance of being reducible to ſtrict rule and method, two other circumſtances ought to concur. Firſt, it ought to appear with the cleareſt evidence, that the undertaking is of greater and more general utility than the greater part of common trades; and, ſecondly, that it requires a greater capital than can eaſily be collected into a private copartnery. In the four trades above-mentioned both theſe circumſtances concur.

The joint-ſtock companies, ſays this judicious writer, which are eſtabliſhed for the public ſpirited purpoſe of promoting ſome particular manufacture, over and above managing their own affairs ill, to the diminution of the general ſtock of the ſociety, can, in other reſpects, ſcarce ever fail to do more harm than good. Notwithſtanding the moſt upright intentions, the unavoidable partiality of their directors to particular branches of the manufacture, of which the undertakers miſlead and impoſe upon them, is a real diſcouragement to the reſt, and neceſſarily breaks, more or leſs, that natural proportion which would otherwiſe eſtabliſh itſelf between judicious induſtry and profit, and which, to the general induſtry of the country, is of all encouragements, the greateſt and the moſt effectual.

Company, *African*; ſometimes called "Royal African Company," the name of the original inſtitution. The firſt commercial voyage from England to the coaſt of Guinea was in 1536, but nothing like a company was formed till the year 1588, when queen Elizabeth granted a patent for ten years to come, to ſome merchants of Exeter, and other perſons for an excluſive trade to the rivers Senegal and Gambia. In 1618, king James I. granted a charter for eſtabliſhing a joint-ſtock company; but ſeparate traders continuing to reſort to the coaſt, the company was ſoon diſſolved. Another company was erected by charter in 1631, which met with little ſucceſs; and in 1651, the parliament granted a charter for five years to the Eaſt India company, for trading to the Gold coaſt in their way to India. The demand for negroes in the Weſt India and American plantations increaſing conſiderably, another excluſive African or Guinea company was incorporated in 1662, at the head of which was the duke of York, joined with many perſons of rank and diſtinction. This company, like thoſe that had preceded it, was unſucceſsful, and its charter was ſoon after revoked by conſent of the parties aſſociated in the enterprize, in conſequence of which another excluſive company was incorporated by letters patent in 1672. They raiſed a capital of 111,000*l.* and improved the trade conſiderably; but at the revolution, the Weſt India planters joined the ſeparate traders in aſſerting that they were always beſt ſerved with ſlaves when the trade was free to all perſons; and excluſive companies, whoſe privileges had not been ſanctioned by parliament, being conſidered inconſiſtent with the declaration of rights, the trade became open again; but all private traders were to pay 10 per cent. to the company, towards maintaining the forts and factories on the coaſt. This contribution was however found inſufficient, and in 1730 parliament granted 10,000*l.* for the purpoſe, which was continued annually till 1744, when, in conſequence of the war, 20,000*l.* was granted, and in almoſt every year ſince, a ſum has been appropriated by parliament to this purpoſe.

As all the joint-ſtock companies which had been eſtabliſhed for this trade had appeared incompetent to carry it on with advantage, it was in 1750 (23 Geo. II. c. 31.) transferred to a regulated company, the members of which are deemed a body corporate and politic, under the title of *The Company of Merchants trading to Africa,* but are prohibited from trading in their corporate capacity, from having any joint or transferable ſtock, and from borrowing money under their common ſeal. Any perſon intending to trade to Africa, may become free of this company on payment of forty ſhillings; and out of the monies thus received, a ſum not exceeding 800*l.* is allowed for the ſalaries of clerks and agents at London, Briſtol, and Liverpool, the houſe-rent of their office at London, and all other expences of management, commiſſion, and agency in England. What remains of this ſum, after defraying theſe different expences, they may divide among themſelves, as compenſation for their trouble, in what manner they think proper. The forts, factories, &c. poſſeſſed by the old company on the coaſt of Africa, are veſted in the preſent company, who continue to receive an annual ſum from parliament (generally about 13,000*l.*) for the ſupport of theſe eſtabliſhments: the ſum granted in the year 1806 was 18,000*l.* For the proper application of this ſum, the committee is obliged to account annually to the curſitor baron of the exchequer, which account is afterwards to be laid before parliament.

The company is under the management of a committee of nine perſons, three being choſen for London, three for Briſtol, and three for Liverpool, annually. The committee are enjoined to lay an annual account of the application of the money granted to them before parliament.

Although by the 4th of Geo. III. c. 20. the fort of Senegal, with all its dependencies, had been veſted in this company, yet in the year following (by the 5th of Geo. III. c. 44.) not only Senegal and its dependencies, but the whole coaſt from the port of Sallee, in South Barbary, to cape Rouge, was exempted from the juriſdiction of that company, and veſted in the crown; the trade to it being declared free to all his majeſty's ſubjects.

Before the eſtabliſhment of the Royal African company, there had been three other joint-ſtock companies ſucceſſively erected one after another, for the African trade. They were all equally unſucceſsful. They all, however, had excluſive charters, which, though not confirmed by act of parliament, were in thoſe days ſuppoſed to convey a real excluſive privilege.

COMPANIES, *Engliſh.* The *Eaſt India Company* was eſtabliſhed by charter dated Dec. 31, 1600, by which the earl of Cumberland and 215 other perſons were authorized to carry on an excluſive trade to all parts of the Eaſt Indies, for 15 years; under the title of "The Governor and Company of Merchants of London trading to the Eaſt Indies." They raiſed 72,000*l.* in ſhares of 50*l.* each, and fitted out five ſhips, which accompliſhed their firſt voyage very ſucceſsfully, in two years and ſeven months.

Having carried on the trade for about ten years, with different degrees of ſucceſs, they obtained another charter dated May 31, 1610, by which the company was made perpetual. They had not yet adopted the mode of trading under one joint ſtock, but carried it on in ſeveral copartnerſhips and leſſer ſtocks. In 1613 the proprietors of the ſeveral ſeparate ſtocks, united them into one general joint-capital; and notwithſtanding ſome oppoſition to their trade, both at home, and abroad, they preſerved and extended it, having at this time eſtabliſhed factories at about twenty different places in India. In a vindication of the Eaſt India Company before the privy council, at a ſubſequent period, among other remarks for ſhewing the great difficulties attending an Eaſt India trade, it was aſſerted, that although they had a ſtock of 1,500,000*l.* yet in fifteen years time, *viz.* from 1617 to 1632, their whole profit was no more than 12 and one-half per cent.

In 1637, Charles I. eſtabliſhed a new company to trade to China and Japan, but it was ſoon ruined. The old company likewiſe from its differences with the Dutch Eaſt India company, the encroachments of private adventurers, and other cauſes, fell into decay, and in 1655 it was diſſolved by Cromwell, and the trade laid open. The miſchiefs which followed obliged him to re-eſtabliſh the company about three years after; their joint-ſtock was now 739,782*l.*, of which only one half, or 369,891*l.* was paid in, and was properly their capital. The total exports of the company in three years, ending with 1660, was 227,820*l.* in bullion, and 23,763*l.* in merchandize. After the reſtoration, they obtained a new charter from Charles II. dated April 3, 1661. By this charter it appears that the company had not then one ſole transferable joint-ſtock; but that every one, who was free of this company paid a certain ſum of money to the company on the fitting out of their fleet, for which he had credit in the company's books, and received his proportionate dividend on the profits of the reſpective voyage. The whole inveſtments were made by the company in their corporate capacity; but they were not eſtabliſhed as an irrevocable corporation, as they might be diſſolved on three years notice.

In 1664, the company's ſtock ſold at only 70 per cent., but in conſequence of an inquiry into the ſtate of their affairs, the reſult of which was very favourable, the ſtock ſoon got up conſiderably. New charters were granted in 1669 and 1676, confirming all their privileges. In the latter year, the company having made a conſiderable profit by their trade, agreed, inſtead of making a dividend thereof, to add it to their capital ſtock, ſo as juſt to double the ſame, by which their capital became 739,782 *l.* 10 *s.* In conſequence of the extenſion and ſucceſs of their trade, which enabled them to make large dividends, their ſtock in 1680 ſold from 280 to 300 per cent; but theſe great profits, and the doubtful authority on which they held their excluſive privileges, (not having the ſanction of parliament) being a great temptation to individual adventurers, interlopers, who had often given them much trouble, became again very numerous, and attempts were made to get the trade laid open, or to have it veſted in a regulated company ſimilar to thoſe by which the trade with Turkey and with ſome other countries was then carried on. The company, however, in 1683 found means to obtain a new charter, by which all their former privileges were confirmed, and they were empowered to ſeize the ſhips and merchandize of all interlopers, to raiſe and maintain military forces, to exerciſe martial law, and to eſtabliſh a court of judicature for determining all mercantile cauſes, within their limits. In 1686 they obtained another charter granting them ſtill greater powers and privileges.

Soon after the revolution much popular clamour was raiſed againſt the Eaſt India company; and in 1691 the houſe of commons addreſſed the king to diſſolve the company and incorporate a new one; an opportunity for which ſoon occurred, as in 1693, the charter of the company became void, from their not paying the duty which had been impoſed on their ſtock within the time limited by the act; but a new charter was granted them, on condition of ſubmitting to ſuch regulations as ſhould be ordained before the 29th of September 1694 and which were contained in two charters ſoon afterwards executed.

In 1698 the complaints of the weavers of London againſt the importation of India wrought ſilks, and the company having been prevented by loſſes from making any dividends for ſeveral years, brought it into much diſrepute, and the houſe of commons thought it neceſſary to take the ſtate of their affairs into conſideration. The company thought it prudent to offer to advance 700,000 *l.* for the public ſervice at 4 per cent. intereſt, provided the excluſive trade was legally ſettled on them; but a number of merchants, countenanced by the chancellor of the exchequer, propoſed to advance 2,000,000*l.* at 8 per cent. intereſt, for ſimilar privileges. The latter propoſal was approved, and an act paſſed by which a new company was eſtabliſhed; many difficulties however appeared, with reſpect to their engaging in the trade, till the expiration of the three years notice for determining the old company. During this unſettled ſtate of the Eaſt India trade, the old company's ſtock had in about nine or ten years fluctuated from 300 per cent. to only 37 per cent.

The great contentions which enſued between the old and new companies, ſoon rendered it obvious that little benefit would be derived from the trade, unleſs a coalition between the two rival corporations was effected. This was accompliſhed in 1702, by an agreement that the old company ſhould purchaſe an equal proportion of ſtock in the new company, and that the ſeparate traders, who had ſubſcribed to the new company, but not to their joint-ſtock, ſhould be included in the union. The old company was to keep their ſtock in the new company, in their corporate capacity for ſeven years, then to transfer it to their reſpective members, and reſign their charter to the crown, from which time the new company comprehending the proprietors of both, aſſumed their preſent title of "The united Company of Merchants of England trading to the Eaſt Indies." In 1708 the term of their excluſive trade to India, which was determinable upon three years notice after 1711, and repayment of the ſum they had advanced, was prolonged to three years notice after Lady-day 1726; for which they advanced to government 1,200,000 without any additional intereſt. In 1712 they obtained an act for continuing the trade and corporation capacity of the company, although the ſums they had advanced to government ſhould be repaid; which repayment or redemption of their annual fund, was not to be made till the expiration of three years notice after Lady-day 1733.

The act of parliament being liable to a different conſtruction from what was probably intended, and the term granted being near its expiration, a very powerful oppoſition to its renewal, was raiſed in 1730, and ſpecious propoſals were made to parliament for redeeming the fund of the company, and transferring the trade to a regulated company, with ſimilar privileges. After a very full diſcuſſion of the ſubject, a new agreement was entered into with the company, who agreed to pay 200,000 *l.* towards the ſervice of the current year, and to have the intereſt payable to them by government reduced from 5 to 4 per cent.; in conſideration of which all their excluſive privileges were continued till the expiration of three years notice, to be given after Lady-day 1766, when upon re-payment of their entire capital of 3,200,000*l.* their excluſive privileges were to ceaſe, but the company to continue a corporation for ever, to enjoy the Eaſt India trade in common with all other ſubjects. In conſequence of this reduction of the intereſt received from government, they thought proper to reduce the dividend payable to their proprietors from 8 to 7 per cent. and ſoon after to 6 per cent.

In 1743 the company propoſed to advance 1,000,000 *l.* for the ſervice of the year 1744, at 3 per cent. intereſt, on having the term of their excluſive trade enlarged for fourteen years, and being permitted to borrow a million on bonds. This propoſal being accepted, the debt from the public to the company became 4,200,000*l.*, and the excluſive trade was now extended to three years notice, to be given by parliament after Lady-day 1780, with the former proviſion, that, after ſuch determination, the company ſhould continue to have a common right with other ſubjects in the trade to India.

The company not ſubſcribing to the reduction of intereſt propoſed in 1749, the ſpeaker of the houſe of commons was ordered to give them notice that the ſum due from government would be paid off, unleſs they ſubſcribed before May 30, 1750: with this it was deemed prudent to comply, but a condition was made, that in order to enable the company to reduce their bond debt, they ſhould be empowered to raiſe money by the ſale of 3 per cent. annuities, to the amount of the debt of government to the company. The annuities thus ſold were known by the title of 3 per cent. India annuities, and were for many years payable at the India houſe, but are now conſolidated with the 3 per cent. reduced bank annuities.

Hitherto the company had not aſpired beyond their original character of merchants, and merely poſſeſſed factories at the principal ports to which they traded; theſe factories were, for the ſafety of their merchandize and the protection of their ſervants, converted into forts, which rendered it neceſſary to maintain a military eſtabliſhment. Thus poſſeſſed of the means of offence as well as defence, they made conſiderable exertions to oppoſe the progreſs of the French in thoſe parts; and as the two companies each endeavoured to procure the aſſiſtance of the neighbouring native princes, the field of intereſt and ambition became much enlarged. In 1751, the company ſent a conſiderable military force into the province of Arcot to ſupport the nabob againſt his rival, who was powerfully aſſiſted by the French; in which conteſt they were engaged with little intermiſſion for ſeveral years. In Bengal, the company had carried on their commercial intercourſe without any connexion with territorial authority, till the death of the ſubah Ali-Verdi-Khan, in 1756. This prince had viewed their increaſing opulence and power with great jealouſy, and a ſhort time before his death gave a remarkable charge to his ſucceſſor, in which he cautioned him to keep in view the power of the European nations in his country, and to free himſelf from their influence as ſoon as poſſible. "The power of the Engliſh is great; reduce them firſt; the others will then give you little trouble. Suffer them not to have forts or ſoldiers; if you do, the country is not yours." In attempting to put this advice into execution, Sou-Rajah-Dowla was completely defeated by the company's forces, and the new ſubah of their appointment, beſides paying to the company a very large ſum for their loſſes and expences, ceded to them a conſiderable territory in the vicinity of Calcutta. On the coaſt of Coromandel, hoſtilities were carried on againſt the French ſettlements with unequal ſucceſs, but ultimately to the advantage of the Engliſh, upon which the ſubah of the Decan concluded a treaty with the company, and ceded to them the entire circar of Maſulipatam. In 1760, the company's forces completely defeated thoſe of France, and in the following year captured Pondicherry, the chief of the French ſettlements in India; ſince which events the power of France in India has been very inſignificant.

Such was the commencement of the company's acquiſitions of territory, which they have ſeized every ſubſequent opportunity of extending, till the ſovereigns of India, whoſe protection they formerly courted, have ſunk into the ſituation of their dependents, and hold their precarious dignities at the will and pleaſure of a ſociety of foreign traders.

The annual ſales of the imports of the company for ſixteen years preceding 1757, amounted on an average to about 2,055,000*l.*; and for the ſame period, the exported goods and ſtores amounted annually, at their prime coſt, to 238,000*l.*; the bullion exported to 690,000*l.* per annum, and they paid in diſcharge of bills of exchange 190,000*l.* per annum.

Early in 1764, on the receipt of ſome unpleaſant news from Bengal, India ſtock fell 14 per cent. The general adminiſtration of the company's affairs, both at home and abroad, became ſoon after the ſubject of much diſcuſſion; and on 29th Auguſt 1766, the court of directors received a notice from the ſecretaries of ſtate, that an inveſtigation would take place in the next ſeſſion of parliament. The adminiſtration laid claim to the territories which the company had acquired in India, with the revenue ariſing from them, as of right belonging to the crown; but as the company were very unwilling to have this new ſource of wealth taken out of their hands, a temporary agreement was made for two years, by which the company, in compenſation for this claim, agreed to pay to government 400,000*l.* a year. In 1769, the agreement was renewed for five years, and the territorial acquiſitions and revenues in India ſecured to the company for that term, with a ſtipulation that the company ſhould be allowed to increaſe their dividend to 12½ per cent., but not to increaſe it more than one per cent. in one year.

They now became involved in a war with the famous Hyder Ally, in conſequence of which, and of the miſconduct of their ſervants in India, the concerns of the company, from the moſt flouriſhing ſituation, were brought into the greateſt embarraſſments. Select and ſecret committees of the houſe of commons were appointed to inveſtigate the ſtate of their affairs; and in 1773, it appeared, not only that they were unable to make the ſtipulated annual payment to government, but that it was neceſſary to aſſiſt them with a loan of 1,400,000. Till this ſum ſhould be repaid, the dividend to their proprietors was not to exceed 6 per cent., and afterward not to exceed 7 per cent. till their bond debt was reduced to 1,500,000*l.* From theſe circumſtances, the price of the company's ſtock fell conſiderably from the latter part of 1772 till February 1774, when their affairs began to wear a brighter aſpect. In 1776, the loan from government had been repaid, and their ſituation being otherwiſe improved, the dividend on their ſtock was raiſed to 8 per cent.

Statement of the Company's Revenues, at their different Settlements in India, in the Year ending April 1777.

To expences in Bengal, civil, military, and fortifications	£1,350,000	By nett revenues in Bengal	£2,500,000
To ditto at Fort St. George	560,000	Benares tribute	290,000
To ditto at Bombay	360,000	Oude ſubſidy	370,000
		By revenues of Fort St. George and the Circars	560,000
	2,270,000	Tanjore ſubſidy	160,000
Nett balance of the year's revenues	1,770,000	By revenues of Bombay, &c.	160,000
	£4,040,000		£4,040,000

On an average of ten years, ending with 1777, the company's exports in goods were about 490,000*l.*; in bullion, 110,000*l.*; and the ſum paid in diſcharge of bills of exchange, 458,000*l.* per annum. By the aid afforded from the revenues, their inveſtments were increaſed, ſo as to produce about 3,330,000*l.* per annum.

In 1779, an act was paſſed for continuing the territories and revenues in India in the poſſeſſion of the company for one year, which in 1780 was continued for another year. In June 1781, it was agreed to offer to pay into the exchequer 400,000*l.*, in full diſcharge of all claims of the public upon the company up to the 1ſt of March; and as, in the preceding year, they had received notice that the 4,200,000*l.* due to them from government would be paid off on the 10th of April, 1783, it became neceſſary to enter into a new agreement, the conditions of which were, that the company ſhould continue to enjoy their excluſive privileges to the 1ſt of March, 1794, then to ceaſe and determine, upon the former conditions of three years previous notice, and the repayment of all ſums due to them. The ſurplus of their nett profits, after paying their dividends, were appropriated, three fourths for the ſervice of government, and one fourth to be retained by the company; and they were reſtricted not to increaſe the dividend of 8 per cent. more than 1 per cent. in any year. This reſtriction was, however, ſoon found unneceſſary; for the nett profits of the company for the year ending 1ſt of March, 1782, did not amount to ſo much as a dividend of 8 per cent. on their ſtock by 22,023*l.*; in conſequence of which, it became neceſſary for government to allow a farther time for the payment of 396,466*l.* 2*s.* 6*d.*, which was due from the company for cuſtoms, beſides a part of the ſum which they had agreed to pay in 1781; and they were at the ſame time empowered, notwithſtanding the above deficiency, to continue their dividends at 8 per cent. In the following year, the war in India, and other circumſtances, increaſed the embarraſſment of the company's affairs; and, by a ſtatement of their accounts to the 1ſt of March, 1783, it appeared that the nett profits of that year did not amount to a dividend of 8 per cent. by 255,813*l.*, which dividend they were nevertheleſs authorized by parliament to continue; and, to enable them ſo to do, government iſſued exchequer bills to the amount of 300,000*l.*, which the bank undertook to lend money upon to the company.

The long and expenſive war in which the company had been engaged in India, terminated in March 1784, by the ratification of peace with the Myſorean government; but the conſequence of this war, in addition to the war in Europe, was the general derangement of the company's affairs both at home and abroad. In December 1783, February and May 1784, the directors laid before parliament ſuch accounts as they then poſſeſſed, reſpecting the general ſtate of their finances. But the impoſſibility of drawing any ſatisfactory information from ſtatements made up in ſuch a ſituation of their affairs, with the apprehenſions which the meaſures then in agitation, relative to the future government of India, had excited in the public mind, reduced the credit of the company to the loweſt ebb. Their ſtock ſold as low as 118½; their bonds at home, bearing 5 per cent. intereſt, were negociated from 2½ to 4 per cent. diſcount; their bonds and certificates, at Bengal and Madras, bore from 18 to 40 per cent. diſcount; at Bombay 50 per cent.; and orders on the treaſury there ſold at 65, and upwards, per cent. diſcount.

It now became a general conviction, that the company was incompetent to the political government of the extenſive territories which they had acquired. A Board of Controul was therefore eſtabliſhed, compoſed of a certain number of commiſſioners to be appointed by the king, and removeable at his pleaſure. This board was authorized to check, ſuperintend, and controul, the civil and military government and revenues of the company. The diſpatches tranſmitted by the directors to the different preſidencies were to be previouſly ſubjected to the inſpection of the Board. The appointment of governor-general, preſident, or counſellor in the different preſidencies, was made ſubject to the approbation and recall of his majeſty; and ſuch other regulations adopted, as in a great meaſure deprived the company of that political and civil authority which they had ſuffered to be ſo groſsly abuſed.

In 1786 ſome further regulations were made reſpecting the government of India; and, as the company's trade was increaſing, particularly in the article of tea, their import of which had been greatly augmented by the arrangement of the commutation act, they were ſaid to require a greater capital, and were authorized to create 800,000*l.* new ſtock, on which they raiſed 1,240,000*l.* at the rate of 155 per cent. In 1789 they obtained another act, enabling them to add 1,000,000*l.* to their capital, which thus became 5,000,000*l.*

In the beginning of 1793, the term of the company's excluſive privileges being nearly expired, the ſubject of laying open the trade to India was again diſcuſſed, and though it was not thought proper to riſk the loſs and confuſion which muſt unavoidably attend any attempt to take ſuch an immenſe concern out of the hands in which it has ſo long continued, a ſtipulation was made in the agreement for the renewal of the charter, that ſuch regulations ſhould be adopted as to admit of a free exportation by private perſons on their own account, of any goods of the growth, produce, or manufacture of Great Britain or Ireland; and of a free importation of ſuch ſorts of the raw materials of the Eaſt Indies as are uſed in the manufactures of Great Britain or Ireland; that the company ſhould be obliged to provide ſhipping for the carriage of the private trade, at as low a freight as it could be furniſhed by private merchants; and that they ſhould licenſe a proper number of agents to reſide at the company's ſettlements, under their protection, for the management of the private trade. On theſe conditions the company's term in the excluſive trade was enlarged for 20 years, or to the 1ſt of March, 1814, with the former proviſo, that if, after the expiration of that term, their right to the ſole trade ſhall ceaſe, in conſequence of three years previous notice being given by parliament, and the repayment of ſuch ſums as may be then due from the public, they ſhall continue a corporation, with power to carry on a free trade in common with other perſons.

On this occaſion, the total income of the company, ariſing both from their territorial revenues and their commercial concerns, was ſtated as follows:

The nett annual income in rents and profits of trade, taken in the moſt unfavourable light to the company, and ſuppoſed to be conſiderably under the mark, was rated at - - -		£2,329,164
Subject to the following payments, *viz.*		
Intereſt of 3,200,000*l.* on bond, at 4 per cent. - - -	£128,000	
Ditto of 6,669,082*l.* debt in India, at various rates of intereſt, on a medium about 8¾ per cent. - -	561,923	
Dividend of 8 per cent. on their capital of 5,000,000*l.* - - - - -	400,000	
		1,089,923
Leaving a nett annual ſurplus of - - - -		£1,239,241

Of this ſurplus it was propoſed to appropriate 500,000*l.* per ann. to the reduction of the debt in India, to pay 500,000*l.* per annum to government in half-yearly payments, and to pay an increaſed dividend of 10 per cent. to their proprietors on 6,000,000*l.* to which ſum their capital was now raiſed.

This annual ſurplus, if it really exiſted at the time to which the above account refers, was of very ſhort duration. In 1795 the company found themſelves unable to continue the propoſed contribution to government; and the intrigues of Tippoo Saib with the French, and with ſome of the native powers, which obliged the company to keep up a large military eſtabliſhment, and ſoon after to engage in another expenſive war, not only reduced the ſurplus of their revenues, but occaſioned a conſiderable increaſe of debt in India, which has ſince been further augmented in conſequence of hoſtilities with Dowlut Rao Scindia and Jeſwunt Rao Holkar.

In order to furniſh ſome idea of the extent of the company's commercial and financial concerns, the following accounts are ſubjoined.

The amount of all goods ſold at the Eaſt India Company's ſales, from the 1ſt of March 1805 to the 1ſt of March 1806.

The vaſt concerns of this company are under the management of twenty-four directors, who are formed into different committees; each committee having the ſuperintendence of a particular department of the company's buſineſs. At the general courts of proprietors, perſons poſſeſſing 1000*l.* ſtock have one vote; 3000*l.* two votes; 6000*l.* three votes; and 10,000*l.* four votes. The number of proprietors entitled to vote, on the 8th of April 1800, was 2163, and the number of votes 2832.

Company, *Hamburgh*, is the oldeſt trading eſtabliſhment in the kingdom; though not always known by that name, nor reſtrained to thoſe narrow bounds under which it was afterwards confined. It was firſt called, the Company of Merchants trading to Calais, Holland, Zealand, Brabant, and Flanders: then it acquired the general title of Merchant-adventurers of England; as being compoſed of all the Engliſh merchants who traded to the Low Countries, the Baltic, and the German ocean. Laſtly, it was called the Company of Merchant-adventurers of England trading to Hamburgh.

This company was not a ſociety of dealers, each furniſhing a part of the ſum to conſtitute the capital ſtock of the company; but a mere aſſociation, or body of merchants, who had nothing in common, but the grant and privilege of trading to Hamburgh, and ſome other cities of Germany; each managing his own commerce, and trading on his own foundation; only obſerving a certain diſcipline, and ſome regulations, which none but the company could eſtabliſh or change.

This company was firſt incorporated by Ed. I. in 1296; and eſtabliſhed again, by charter, in 1406, under the reign of Henry IV. It was afterwards confirmed and augmented with divers privileges, by many of his ſucceſſors; among the reſt, by Henry V. in 1413; Henry VI. in 1422; Henry VII. in 1493, 1505, and 1506; Henry VIII. in 1509, 1517, and 1536; Edward VI. in 1547; queen Mary, in 1553; Elizabeth, in 1564, and 1586; James I. in 1605; and Charles II. in 1661. But of all theſe charters, none but thoſe of Henry IV. Henry VII. Elizabeth, James, and Charles, were of any importance, or gave the company any thing new; the reſt being only confirmations. Before the charter of Henry IV. all the Engliſh merchants, who trafficked out of the realm, were left to their own diſcretion, and managed their affairs with foreigners as might be moſt for their reſpective intereſts; without any regard to the general commerce of the nation.

Henry obſerving this diſorder, endeavoured to remedy it, by uniting all the merchants in his dominions into one body; wherein, without loſing the liberty of trading each for himſelf, they might be governed by a company; and be ſubject to regulations, which ſhould ſecure the general intereſt of the national commerce, without prejudice to the intereſt of particulars. With this view, he granted all the merchants, of his ſtates, particularly thoſe of Calais, then in his hands, a power of aſſociating themſelves into a body politic, with directors and governors, both in England and abroad; to hold aſſemblies both for the direction of buſineſs and the deciding of controverſies among merchants; make laws, puniſh delinquents; and impoſe moderate duties and taxes on merchandizes and merchants to be employed in the ſervice of the corporation.

Theſe few articles of the charter of Henry IV. were afterwards much augmented by Henry VII. who firſt gave them the title of Merchant-adventurers to Calais, Holland, &c. gave them a power of proclaiming and continuing free fairs at Calais; and ordered, that to be reputed a member of the ſociety, each perſon ſhould pay twenty marks ſterling; and that the ſeveral members ſhould attend the general meetings, or courts, appointed by the directors, whether at London, Calais, or elſewhere.

The inexecution of this laſt article and contempt of ſome of the reſt, occaſioning great inconveniences to the company's affairs, another charter was procured, whereby the pain of impriſonment was menaced, for thoſe who ſhould abſent themſelves from the meetings without lawful cauſe, or ſhould diſobey the laws. A petition being made to queen Elizabeth, in 1564, for an explanation of certain articles in the charter of Henry VII. and a confirmation of the reſt granted by other kings; that princeſs, by a charter of the ſame year, declares, that to end all diſputes, they ſhould be incorporated anew under the title of the "Company of Merchant-adventurers of England;" that all who are members of the former company ſhould, if they deſire it, be admitted members of this; that they ſhould have a common ſeal; that they ſhould admit into their ſociety what other perſons, and on what terms, they pleaſe; and expel them again on miſbehaviour; that the city of Hamburgh, and neighbouring cities, ſhould be reputed within their grant, together with thoſe of the Low Countries, &c. in that of the former company; that no member ſhould marry out of the kingdom, nor purchaſe lands, &c. in any city beyond ſea; and that thoſe who do, ſhall be *ipſo facto* excluded for ever.

Twenty-two years after this firſt charter, queen Elizabeth granted them a ſecond; confirming the former, and further granting them a privilege of excluſion, with a power of erecting in each city within their grant, a ſtanding council.

The woollen manufacture being the principal object of their application, they met with great oppoſition; firſt, from the Hanſe, who forced them frequently to change their mart, or ſtaple; and afterwards under king James I. who having erected a corporation in 1616, in favour of ſome private perſons, who offered to ſet up a manufacture for dyeing and preſſing cloths, &c. under pretence thereof the company of merchant-adventurers were prohibited dealing therein. But that project not ſucceeding, and the charter being revoked two years afterwards, the merchant-adventurers, whoſe company had been diſſolved two years before, were reſtored in 1617, to their ancient privileges, and a new charter was given them, confirming their excluſive rights; and allowing them to have officers in the ſeveral cuſtom-houſes, to have an eye that they were not prejudiced in their woollens, under pretence of the like merchandizes, which others were allowed to ſend to other parts. This charter of king James, is the laſt of thoſe confirmed by Charles II. in the grand charter of 1661.

The revolutions which had happened in the Low Countries towards the end of the ſixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn it almoſt wholly to the ſide of Hamburgh, and the cities on the German ocean; from which change ſome people took occaſion to change its name to that of the Hamburgh company, though the ancient title of Merchant-adventurers is ſtill retained in all their writings.

This ſociety was greatly reduced, when its trade was laid open by William III. and the company is now extinct.

COMPANY *of Merchants of the Staple* was incorporated by Edward III. Their factory was at Middleburgh, in Zealand; but the ſtaple being removed, in 1389, to Calais, it was ſoon after, *viz.* in 1390, removed from thence to England.

COMPANY, *Ruſſia*. This was firſt projected towards the end of the reign of king Edward VI. executed in the firſt and ſecond years of Philip and Mary; but had not its perfection, till its charter was confirmed by act of parliament, under queen Elizabeth, in 1566. It had its riſe from certain adventurers, who were ſent in three veſſels on the diſcovery of new countries; and to find out a north-eaſt paſſage to China; theſe, falling into the White ſea, and making up to the port of Archangel, were exceedingly well received by the Muſcovites; and at their return, ſolicited letters patent to ſecure to themſelves the commerce of Ruſſia, for which they had formed an aſſociation.

The charter was promiſed them by Edward VI. but he dying, was firſt diſpatched by queen Mary, in 1555. By this charter, the aſſociation was declared a body politic, under the name of the "Company of Merchant-adventurers of England, for the diſcovery of lands, territories, iſlands, &c. unknown or unfrequented." Their privileges were, to have a governor, four conſuls, and twenty-four aſſiſtants, for their commerce; for their policy, to make laws, inflict penalties, ſend out ſhips to make diſcoveries, take poſſeſſion of them in the king's name, ſet up the banner royal of England, plant them; and laſtly, the excluſive privilege of trading to Archangel, and other ports of Muſcovy, not yet frequented by the Engliſh.

This charter, not being ſufficiently guarded, was confirmed by parliament in the eighth year of queen Elizabeth; wherein it was enacted, that in regard the former name was too long, they ſhould now be called "Company of Engliſh Merchants for diſcovering new trades;" under which name, they ſhould be capable of acquiring and holding all kinds of lands, manors, rents, &c. not exceeding a hundred marks per ann. and not held of her majeſty; that no part of the continent, iſland, harbour, &c. not known nor frequented before the firſt enterprize of the merchants of their company, ſituate to the north, or north-weſt, or north-eaſt of London; nor any part of the continents, iſlands, &c. under the obedience of the emperor of Ruſſia, or in the countries of Armenia, Media, Hyrcania, Perſia, or the Caſpian ſea, ſhould be viſited by any ſubjects of England, to exerciſe any commerce without the conſent of the ſaid company, on pain of confiſcation. The ſaid company ſhall uſe no ſhips in her new commerce, but thoſe of the nation; nor tranſport any cloths, ſerges, or other woollen ſtuffs, till they have been dyed and preſſed. That in caſe the company diſcontinue of itſelf to unload commodities in the road of the abbey of St. Nicolas, in Ruſſia, or ſome other port, on the north coaſts of Ruſſia, for the ſpace of three years, the other ſubjects of England ſhall be allowed to traffic to Narva, while the ſaid company diſcontinues its commerce into Ruſſia, only uſing Engliſh veſſels.

This company ſubſiſted with reputation almoſt a whole century, till the time of the civil wars. It is ſaid, the czar then reigning, hearing of the murder of king Charles I. ordered all the Engliſh in his ſtates to be expelled; which the Dutch taking the advantage of, ſettled in their room

After the reſtoration, the remains of the company re-eſtabliſhed part of their commerce at Archangel, but never with the ſame ſucceſs as before: the Ruſſians being now well accuſtomed to the Dutch merchants, and merchandize.

This company ſubſiſts ſtill, nearly on the foot of that of Hamburgh, and the northern and Turkey companies; i. e. each member thereof trafficks for himſelf, and on his own foundation; only paying an acknowledgement as fine for admiſſion, which was reduced by 10 and 11 W. III. c. 6, to five pounds; beſides ſome other dues impoſed, from time to time, for the occaſions of the company, and the commerce in general. It is under the direction of a governor, four conſuls, and aſſiſtants.

COMPANY, *Eaſtland*, is eſtabliſhed on ſimilar ground with that of Hamburgh; from whence it appears to have been diſmembered.

Its charter is dated in the year 1579. By the firſt article the company is erected into a body politic, under the title of the "Company of Merchants of the Eaſt;" to conſiſt of Engliſhmen, all real merchants, who have exerciſed the buſineſs thereof, and trafficked through the Sound, before the year 1568, into Norway, Sweden, Poland, Livonia, Pruſſia, Pomerania, &c. as alſo Revel, Koningſberg, Dantzick, Copenhagen, &c. excepting Narva, Muſcovy, and its dependencies. Moſt of the following articles grant them the uſual prerogatives, of ſuch companies; as a ſeal, governor, courts, laws, &c.

The privileges peculiar to this company are, that none ſhall be admitted a member who is already a member of any other company; nor any retail dealer at all. That no merchant qualified, be admitted without paying 6 *l.* 13 *s.* 6 *d.* By 29 C. II. c. 7. the fee of admiſſion into this company was reduced to 2 *l.* That a member of another company, deſiring to renounce the privileges thereof, and to be received into that of the Eaſt, ſhall be admitted *gratis;* provided he procures the ſame favour for a merchant of the Eaſt, willing to fill his place. That the merchant adventurers who never dealt in the Eaſt, in the places expreſſed in the charters, may be received as members of the company on paying forty marks; that, notwithſtanding this union of the adventurers of England with the company of the Eaſt, each ſhall retain its rights and privileges. That they ſhall export no cloths but what are dyed and preſſed, except a hundred pieces per annum, which are allowed them *gratis*.

This charter was confirmed by Charles I. in 1629, with this addition; that no perſon of what quality ſoever, living in London, ſhould be admitted a member, unleſs he were free of the city.

This company was complained of as a monopoly, and firſt curtailed by legal authority in 1672; and ſince the declaration of rights in 1689, exiſts only in name; but they ſtill continue to elect their annual officers, who are a governor, deputy, and twenty-four aſſiſtants.

COMPANY, *Turkey*, or *Levant*. This once flouriſhing body had its riſe under queen Elizabeth, who, in 1581, incorporated a ſmall number of merchants, with the privilege of an excluſive trade to Turkey for ſeven years. James I. in 1605, confirmed their charter, with the addition of ſome new privileges. During the civil wars ſome innovations were made in the government of the company; many perſons having been admitted members, not qualified according to the charter, or who did not conform to the regulations preſcribed, in conſequence of which Charles II., upon his reſtoration, endeavoured to place it upon its ancient baſis, for which purpoſe he gave them a new charter, containing a confirmation of the old one with ſome additional articles. By this charter the company was declared to be a body politic, capable of making laws, &c. under the title of "The Company of Merchants of England trading to the Seas of the Levant." The number of members was not limited, but no perſon reſiding within twenty miles of London, excepting noblemen and gentlemen of quality, was to be admitted into the company, unleſs firſt made free of the city of London: thoſe under 26 years of age were to pay 25 *l.* for their admiſſion, and thoſe above that age 50 *l.* Theſe fines were reduced by an act paſſed in 1753, (26 Geo. II. c. 18.) by which it is directed that every ſubject of Great Britain deſiring admiſſion into the Turkey company, ſhall be admitted within thirty days after ſuch requeſt, and ſhall enjoy all the liberties and privileges of the company, on paying for ſuch admiſſion the ſum of 20 *l.*

All perſons free of the company may, ſeparately or jointly, export any goods or merchandize (not prohibited) from any place in Great Britain, to any place within the limits of the company's charter, in Britiſh or plantation built ſhips, navigated according to law, at any time, and to any perſons whomſoever, being free of the company, or to the ſons or apprentices of freemen, ſo long as they ſhall remain under, and ſubmit to, the direction of the Britiſh ambaſſador and conſuls for the time being; and may alſo import, in like manner, any commodities purchaſed within the company's limits, on payment of the government duties, and ſuch impoſitions as ſhall be aſſeſſed upon all merchandize ſo exported or imported, or upon ſhips laden therewith, for defraying the neceſſary expences of the company.

The company is under the management of a governor, a deputy governor, and fifteen directors; they have alſo a deputy governor in every city and port where there are any members of the company. They preſent the ambaſſador which the king is to keep at the Porte, and elect two conſuls for Smyrna and Conſtantinople; allowing a fixed ſalary or penſion to the ambaſſador and conſuls, and even to their chief officers, as ſecretary, chaplain, interpreters, and janizaries, that they may not have any pretence for raiſing any ſum whatever on the merchants or merchandize. For defraying theſe charges the company have power to levy duties on the merchandize imported or exported by their members; but of late years they have frequently found it neceſſary to apply to parliament for pecuniary aſſiſtance.

The commerce of this company was formerly very conſiderable, having been eſtimated nearly equal to that of the Eaſt India company in extent, and much more advantageous to Great Britain; but the convenient ſituation of the French ports in the Mediterranean for the Levant trade, gives that country ſuch a decided advantage, that the commerce of Great Britain with Turkey has long been on the decline. In 1797, in order to avoid the hazard to which Britiſh veſſels in the Levant trade were expoſed in conſequence of the war, an act was paſſed giving permiſſion to the members of the Turkey company to import the goods uſually brought from Turkey, Egypt, or other parts of the Turkiſh dominions in the Levant ſeas, from any port whatſoever, either in Britiſh veſſels or veſſels belonging to any friendly nation, on paying, if in Britiſh veſſels, the ſame duties which would have been payable if the goods had been imported directly from the place of their growth, and, if in foreign veſſels, the duties to which they were before liable; but no entry of ſuch goods was to be made at the cuſtom houſe till the importer produced a certificate of his being a member of the Turkey company, and that he had paid the company's duties, and in all reſpects conformed to the company's regulations.

Company, *South Sea*, originated in a project for relieving the government from the embarraſſment of a large amount of unfunded debts, and conſiderable deficiencies in the funds appropriated for the payment of others; the proprietors of theſe debts being incorporated for the oſtenſible purpoſe of eſtabliſhing a trade to the ſouth ſeas and the N.W. coaſt of America. The capital of the company was 9,177,967*l.* 15*s.* 4*d.*; but this being ſubſcribed wholly in government ſecurities, they iſſued bonds in 1712, for raiſing 200,000*l.* in caſh in order to fit out their firſt mercantile adventure. In the following year, they obtained the Aſſiento contract, by which they agreed to import into the Spaniſh Weſt Indies 144,000 negroes, within the term of 30 years, at the rate of 4800 in each year, and were allowed to ſend a ſhip of 500 tons yearly to trade with the Spaniſh ſettlements, on condition that the king of Spain ſhould have a fourth part of the gain by ſuch ſhip, and receive five per cent. on the nett gain of the other three parts. See Assiento.

The firſt voyage of their annual ſhip was in 1717, and the company were again empowered to borrow money under their common ſeal, for carrying on their trade, or to enable them to fulfil an engagement with government to advance two millions towards carrying into execution a propoſed reduction of intereſt on the public debts. On the war breaking out in the following year, a ſtop was put to their trade with the Spaniſh Weſt Indies, by the ſeizure of their effects, by which they ſuſtained a very conſiderable loſs.

Soon after this interruption of their commercial concerns, they engaged in a ſcheme for converting ſome of the government terminable annuities into redeemable debts. They had, in 1715, for the accommodation of government, agreed to increaſe their capital to 10,000,000*l.*, which, by the annuities now purchaſed, and an advance to government, became 11,746,844*l.* 8*s.* 10*d.*; and although the ſcheme did not completely ſucceed, it prepared the way for the much more extenſive project of taking in all the public debts, and thus reducing all the public funds which then exiſted into one.

The mere rumour of this mercantile project raiſed the price of the company's ſtock to 126 per cent.; and, in the beginning of 1720, while the bill for carrying it into execution was depending in parliament, their ſtock got up from 137 to 319 per cent. As the tranſaction conſiſted merely in taking the public debts at a fixed price, and giving the proprietors, in exchange, a certain quantity of the company's capital ſtock, at prices agreed upon between the company and the ſubſcribers, it is evident that the great gain which the company expected to make, could ariſe only from the current price of their ſtock being conſiderably above its real value. By a variety of artifices, and a general ſtock-jobbing infatuation, it was carried up to the enormous price of 1000 per cent.: the rapidity of its fall, however, exceeded that by which it roſe, as it was in a few weeks down to 130 per cent.; involving in ruin perſons of all deſcriptions who were engaged in the wild ſpeculations of the time. (See Bubble.) Had the tranſaction completely ſucceeded, the capital of the company would have amounted to 43,411,399*l.* 6*s.* 11$\frac{1}{4}$*d.*, but from ſome of the debts remaining unſubſcribed, it became 37,802,483*l.* 14*s.* 0$\frac{1}{2}$*d.* of which four millions were purchaſed in 1722 by the bank, and in the following year the remainder was divided into two equal parts, one of which was to be called the trading capital of the company, and the other to be diſtinguiſhed by the title of "The joint-ſtock of South Sea annuities," ſince called old South Sea annuities.

In 1724, the company undertook the Greenland whale fiſhery, which turned out very unprofitable: after eight voyages, they ſold their ſhips, ſtores, and utenſils, and found that their whole loſs upon this buſineſs, capital and intereſt included, amounted to 237,142*l.* 6*s.* 2*d.*

In 1753, three fourths of their trading capital, which had been reduced by ſums paid off in 1727, 1729, and 1732, to 14,651,103*l.* 8*s.* 1*d.*, was converted into an annuity ſtock called "New South Sea Annuities," only one fourth remaining as their trading ſtock; and, in the following year, they petitioned the king to be allowed to diſpoſe of the trade and tonnage of their annual ſhip under the Aſſiento contract, on account of the little profit they made by it, and to accept of ſuch equivalent as they could obtain from the king of Spain, who at length, to put an end to the many diſputes which had ariſen from this contract, agreed, in 1750, to pay 100,000*l.* to the company, as a compenſation for all claims under the Aſſiento contract, and from that period they have not carried on any trade whatever. The whole buſineſs of the company, therefore, now conſiſts in the management of the following public funds.

Their capital ſtock - -	£3,662,784	8	6
Old South Sea annuities -	11,907,470	2	7
New South Sea annuities - -	8,494,830	2	10
Three per cents., 1751 - -	1,919,600	0	0

The intereſt received from government on all theſe funds, is 3 per cent., but the dividend paid to the proprietors of the company's ſtock, is 3$\frac{1}{2}$ per cent.; on the old and new annuities, 3 per cent.

The company is under the management of three governors, and 21 directors; the qualification required for governor, is the poſſeſſion of 5000*l.* in the company's ſtock; for ſub-governor, 4000*l.*; for deputy-governor, 3000*l.*; and for a director, 2000*l.* Five hundred pounds ſtock, gives a right to one vote at the general courts; 2000*l.* to two votes; 3000*l.* to three votes; and 5000*l.* to four votes.

Company, *Scotch Darien.* This was eſtabliſhed with good proſpect at Edinburgh, in 1695, for the commerce of South America. In 1698, they ſent an armament and a colony, which they endeavoured to eſtabliſh in the iſthmus of Darien, which parts North and South America; but the Engliſh miniſtry not thinking proper to avow and ſupport the firſt ſucceſſes of the company, which had alarmed Spain, ever jealous of this part of her territories, the Scotch colony was diſperſed by the Spaniards in 1699, and thus vaniſhed the beſt project that ever was formed for diſputing with that nation the poſſeſſion of thoſe countries, from which ſhe pretends to exclude all other nations.

Company, *Hudſon's Bay*, was incorporated by charter, dated the 2d of May, 1670, under the title of "The Governor and Company of Adventurers of England, trading into Hudſon's Bay," with the excluſive privilege of trading to all parts within the entrance of the ſtreight commonly called Hudſon's ſtreights. The charter, however, not being confirmed by act of parliament, the company poſſeſs no excluſive rights whatever, any Britiſh ſubject being at liberty to ſail into Hudſon's Bay, to fiſh or traffick with the Indians as freely as the company; all the advantage the company have over other adventurers thither is merely the benefit of their own forts, ſuch as they are, by which their agents can reſide in ſo inhoſpitable a country during the winter, preparatory to their trading with the Indians againſt the arrival of their ſhips in the ſummer. According to the evidence given before a committee of the houſe of commons in 1749, the company then poſſeſſed four ſmall factories, erected at the mouths of the principal rivers, in which they employed about 130 perſons

ſons, and two ſmall houſes with only eight men in each; theſe buildings are neceſſarily ſtrong, as well to guard againſt the climate as againſt other dangers, and are furniſhed with artillery to command reſpect from the Indians; they have therefore been generally called forts, although no military force is kept for defending them: their inability in reſiſting any ſerious attack, was obvious in 1782, when the French, who at former periods had done the company much injury, deſtroyed their ſettlements, forts, merchandize, &c. to the eſtimated amount of near 500,000 *l*.

The capital of the company, it is ſaid, does not exceed 110,000 *l*. which is divided among a very ſmall number of proprietors. The commerce carried on by them is not of great extent, as it ſeldom employs above four or five ſhips of about 300 tons each. The articles exported by them are coarſe duffle cloth or blanketing, guns, piſtols, ſword blades, hatchets, powder and ſhot, ſpirits, tobacco, braſs kettles, buttons, fiſh hooks, looking glaſſes, &c.; the imports conſiſt of large quantities of beaver ſkins, and peltry of all kinds, bed feathers, quills, caſtoreum, whale fins, oil, and a few ſmaller articles.

The company is under the management of a governor, deputy governor, and a committee of ſeven members.

Company, *Sierra Leone,* was ſet on foot in the year 1791, with the philanthropic view of introducing civilization into Africa. The principal means propoſed for effecting this end was the eſtabliſhment of a ſecure factory for carrying on an extenſive commercial intercourſe with the interior; but before the arrangements for this purpoſe were completed, the reception into the ſettlement of near 1200 blacks, who had taken part with Great Britain in the American war, and had petitioned the government to be removed from Nova Scotia on account of the coldneſs of the climate, involved the company in conſiderable difficulties, and gave a new character to the undertaking. Their expences, from various cauſes, became much greater than could have been foreſeen, amounting in the firſt two years and a half to 111,500*l*. and were ſtill further increaſed in 1793 by the war, which at the ſame time greatly interrupted their trade, and ſubjected them to depredations. In October 1794, the colony was attacked by a French ſquadron, and all the moveable property of the company was either carried off or deſtroyed, every building belonging to them burnt, and ſeveral ſhips captured. The company's loſs on this occaſion has been eſtimated at 52,000 *l*. This calamity, combined with their previous expences, ſo greatly diminiſhed the company's funds, as to lay them under a neceſſity of contracting their trade, and reducing conſiderably the ſcale of their eſtabliſhment, which had been at all times ſo limited as ſcarcely to afford ſufficient means of tranſacting the buſineſs and attending to the various wants of an infant ſettlement.

In the year 1798 the colony had made conſiderable progreſs, notwithſtanding the many obſtacles to its advancement. The town conſiſted of about three hundred houſes, with the neceſſary public buildings, and had become a place of conſiderable reſort. It was eſtimated that from one to two hundred natives viſited the ſettlement every day, many of them coming from a diſtance of eighty or a hundred miles, for the purpoſe of exchanging articles of African produce, for Britiſh manufactures. The total number of inhabitants of the colony at this time was about 1200.

In 1800 the company obtained a charter, creating their ſettlement an independent colony, and authorizing the directors to frame laws for its government, to appoint a governor and council, and to make other arrangements for the adminiſtration of juſtice; a ſmall military force was at the ſame time ſent for the defence of the colony. The ſum of 7000*l*. being part of the ſum granted by parliament for the maintenance of African forts, was paid to the company for the erection of a fort; 10,000 *l*. was about the ſame time received from government as a partial indemnification for the expence to which the company had been put in ſettling the Nova Scotians; 4000 *l*. was alſo granted for the ſupport of the civil government of the colony. About this time the company agreed to receive in their colony the Maroon Indians, and ſoon after their arrival, employed them to quell an inſurrection among the Nova Scotians, who had endeavoured to poſſeſs themſelves of the government. A more ſerious attack on the colony was afterward made by ſome of the native chiefs in the neighbourhood, which rendered it neceſſary to adopt additional means of defence.

The ſums ſince granted by parliament for defraying the charges of the civil eſtabliſhment of the company, and for the erection of fortifications, have been as follow:

For the year	1801	£ 4,000
	1802	10,000
	1803	14,000
	1804	14,000
	1805	14 000
	1806	18,000

The trade of the company appears to have been ſucceſsful, ſuppoſing it to have been burthened only with thoſe charges which are ſtrictly commercial, and to have been exempt from the extraordinary loſſes by fire, and the deſtruction of the ſettlement which it has had to ſuſtain. The abolition of the ſlave trade will remove ſome great obſtacles to the ſucceſs of this laudable undertaking, and probably enable it to improve and extend its commercial intercourſe with the natives very conſiderably.

Company, *for the Manufacture of Flour, Meal, and Bread.* During the diſtreſs occaſioned by the great ſcarcity of corn, in the year 1800, a number of perſons formed themſelves into a company, for the purpoſe of eſtabliſhing in London a manufactory of flour, meal, and bread, to be ſold out at reaſonable prices. They were incorporated by parliament, and empowered to ſubſcribe a joint capital, not exceeding 120,000 *l*. in ſhares of 25 *l*. each; their profits being limited to 10 per cent., and the ſurplus, if any, to be at the diſpoſal of parliament. They were limited to ſell only 120,000 ſacks of flour, or meal in a year, to make only 200 ſacks into bread in a week, and to ſell not more than 1000 quarters of wheat in any one week. The managers of the company were prohibited from dealing in corn, flour, or bread, for their own private account; and were required to lay before parliament an annual ſtatement of their receipts and payments, of the quantities of grain purchaſed, with the prices paid for the ſame, of the quantities of grain and flour in ſtore, of the quantities of flour and bread manufactured by the company, and of the debts and credits of the company, with the names of all the members of it, and the number of ſhares held by each. By theſe regulations ſufficient publicity is given to the concerns of the company to prevent it from ever being perverted from the original principle of the eſtabliſhment, and made ſubſervient to ſchemes of monopoly or ſpeculation; and though upon the ſcarcity ceaſing, they diſcontinued making bread, they have carried on the manufacture of flour and meal, and probably contributed to prevent theſe eſſential articles from being unneceſſarily enhanced in price.

The total quantity of wheat purchaſed by the company in the year 1806, was 9182 quarters, for which they paid 32,655*l.* 19*s.*; the quantity of flour manufactured was 10,536 ſacks. The number of proprietors of the company was 330.

The king by an order in council may diſſolve this company on ſix months previous notice being given.

Company, *Dock*. See Dock.

Company, *Dutch Eaſt-India*, had its riſe in the midſt of the ſtruggle which that people had for their liberty; for the Spaniards having forbid all commerce with them, and ſhut up all their ports, neceſſity inſpired ſome Zealanders to ſeek a new north-eaſt paſſage to China.

This enterprize proving unſucceſsful to three ſeveral armaments in 1594, 1595, and 1596, a ſecond company was formed under the name of the "Company of remote Parts;" which, in 1595, took the ordinary route of the Portugueſe to the Indies, and returned in two years and a half's time, with little gain, but good hopes.

This company, and a new one juſt eſtabliſhed at Amſterdam, being united, equipped other fleets; and theſe occaſioned other companies at Amſterdam, Rotterdam, in Zealand, &c, inſomuch that the ſtates ſoon began to apprehend they might be prejudicial to each other. Under this concern they called all the directors of the ſeveral companies together, who all conſented to the union, the treaty whereof was confirmed by the ſtates in 1602, a very remarkable epocha, as being that of the moſt ſolid and celebrated eſtabliſhment of commerce that ever was in the world.

At this time they obtained a charter from the ſtates; and prevailed upon that body, by adminiſtering to its exigencies in the Spaniſh war, to grant them the excluſive privilege of trading to the ſouthern parts of Africa, for a ſhort term of years. The company's capital of 6,500,000 florins (about 541,833 *l.* ſterling) was divided into transferable ſhares, or *actions*, as they are called on the continent, of 3000 florins (about 250 *l.* ſterling each), which were all ſpeedily bought up. The ſuperiority of their trading capital, together with their greater ſkill in commerce and navigation, enabled them to underſell all other nations, even in the foreign markets of Europe. As they alſo fixed the prices of their merchandize to all conſumers, their profits for ſome years were enormous. The annual dividends for the 6 years ending in 1610 were as high as 36 per cent.; and in a ſhort time, the actions roſe from 3000 to 15,000, and at one time ſtood as high as 24,000 florins, 8 times the amount of their prime coſt. The charter, firſt granted in 1602, and ſince renewed from time to time, conferred upon them, beſides the excluſive right of trading to the Eaſt, the ſovereignty (under the ſuperintendence of the ſtates-general) of all the territories which they might acquire in that part of the world, by purchaſe, treaty, or conqueſt, with the full power of appointing their own ſervants; of raiſing whatever force they might deem neceſſary for the defence of their territories; and of enacting laws for the internal adminiſtration of their dominions. In conſequence of this charter, the moſt extenſive that was ever granted to any trading corporation, the company proceeded to arrange their eſtabliſhment, both in Europe and the Eaſt Indies. Their affairs were under the management of ſixty directors, divided into ſeveral chambers; twenty in that of Amſterdam, twelve in that of Zealand, fourteen in that of Delft and Rotterdam, and a like number in thoſe at Sluys and Horn. As each grant expired the company was obliged to procure a new one, which it has already done, four times ſince the firſt; *viz.* one in 1623, for forty-one years, like the firſt; another for twenty-one years, commencing in 1643; and a third in 1665, for forty years; a fourth in advance, commencing in 1698, to end in 1740. Each grant coſt the company a conſiderable ſum; that of 1647 coſt 1,600,000 guilders, and the two following ones more; that of 1698 was confirmed by a placard of the ſtates-general, granted them an excluſive privilege, which was prolonged in 1761, for thirty years more. The average premium paid for theſe renewals was about 270,000 *l.* ſterling, or three millions of florins.

Their factories, reſidences, &c. in the Eaſt Indies, were very numerous; reaching from the Perſian gulf to the coaſt of China: the principal was that of Batavia, the centre of their commerce: here reſided the general, with the ſtate and ſplendor of a ſovereign prince; making war and peace with the eaſtern kings and emperors at pleaſure. They had alſo ſeveral other conſiderable factories on the coaſt of China, in Japan, Malacca, Surat, Amboyna, Banda, Siam, Moluccas, &c. ſeveral on the coaſt of Coromandel, and at Iſpahan, Cape of Good Hope, &c. in all, they numbered forty factories, and twenty-five fortreſſes. They engroſſed the whole trade of the ſpicery in their own hands.

At ſo early a period as the year 1616, this company had no leſs than 45 large veſſels engaged in war and trade, with 10,000 ſoldiers and ſailors in their ſervice, and 4,000 pieces of artillery. However, the flouriſhing ſtate of their affairs was of ſhort duration. The miſmanagement and plunder of the company's ſervants, and the diſputes in which their cruelties, avarice, and imprudence involved them with the native powers during the 17th century, and the diſſenſions which aroſe among the different chambers of the general direction at home, greatly reduced the trade, wealth, and power of the inſtitution. The expence of the military eſtabliſhment alſo increaſed; ſo that at the end of the 18th century, it amounted to 80 veſſels, carrying from 30 to 60 guns, and 25,000 men, ſoldiers included, while the whole dominions in Java, and its dependencies, were farmed for 361,260 dollars. The directors acknowledged that, in 1780, their loſs in the war had exceeded 10 millions of florins, nearly twice the amount of their original capital. In the 18th century the Oſtend Eaſt India company excited the jealouſy of the Dutch company. In 1721, a law was paſſed by the ſtates, prohibiting their ſubjects from ſailing under the Oſtend colours, upon pain of death: and in 1731, this unfortunate aſſociation was diſſolved in conſequence of repreſentations from the different European ſtates intereſted in the Eaſt Indian trade; among which Holland, that is the Dutch company, took the lead. Various precautions have been uſed to ſupport the credit of this company, ſome of which were oppreſſive to the country; nevertheleſs, its ſhares have continued to fall with augmented rapidity. In the period from 1605 to 1779, the dividends have varied from 75 to 10 per cent.; and in many years no dividend at all was iſſued. From 1605 to 1610 (both incluſive), the dividend was, at an average, 36 per cent. From 1610 to 1648, the average was only 21; and from 1771 to 1780, it was no more than 12½ per cent. The price of the actions, which had at firſt riſen to 500, and even 800 per cent. of the prime coſt, fell, in the period from 1770 to 1780, to about 340 per cent., and during that time continued regularly to fall. The laſt dividend this once flouriſhing company made to their proprietors was in the year 1796; but it was not paid till 1799, as their commerce, which had been rapidly declining for the laſt 30 years, was entirely ſuſpended.

Company, *Dutch Weſt India*, was eſtabliſhed in 1621, with an excluſive privilege to trade twenty-four years along the coaſts of Africa, between the tropic of Cancer and Cape of Good Hope; and in America, from the ſouth point of Newfoundland, through the ſtraits of Magellan, that of Le Maire, or others, to the ſtraits of Anian, both in the north and ſouth Sea.

Beſides theſe commercial privileges, the ſtates conferred upon the corporation the right of governing and defending any new colonies which it might acquire; and made it a preſent of ſeveral large veſſels, well manned. They retained to themſelves, however, the nomination of the company's governor-general abroad. The original capital of this aſſociation amounted to 72,000 florins, in transferable ſhares, or actions, of 6000 florins each.

The 74 directors were divided into five chambers (as in the Eaſt India company), out of which, eighteen, with a deputy appointed by the ſtates, were choſen for the general direction of affairs. In 1647, the company renewed its grant for twenty-five years; but it was ſcarce able to hold out the term, on account of its great loſſes and expences in taking the bay of Todos los Santos, Fernambuc, and the greateſt part of Braſil, from the Portugueſe. The weakneſs of this company, which had ſeveral times in vain attempted to be joined to that of the Eaſt Indies, occaſioned its diſſolution at the expiration of its grant.

In 1674, a new company, compoſed of the ancient proprietors and their creditors, was ſettled in the ſame rights and eſtabliſhment with the former. It was to undertake the burden of the old company's debt, amounting to ſix millions, but reduced to 30 per cent.; and was to accredit in its books the proprietors of the old company's ſtock, at the rate of 15 per cent. The creditors, on their part, were to advance an addition of 8 per cent. on their loans; and the ſtockholders were to advance 4 per cent. on their ſhares. The new capital, thus ſcraped together, amounted only to 630,000 florins. The excluſive commerce of the company was limited to a certain part of the African coaſt, beſides the conqueſts they ſhould make; and its principal eſtabliſhments were at Cape Verd, on the Gold Coaſt, at Tobago, Curaſſoa, &c. in America. The reſt of the trade monopolized by the former company was now thrown open to all the ſubjects of the republic. In 1730, when the charter was renewed, the African ſlave-trade was made free, on condition of a certain laſtage being paid to the company; and in 1734, the whole African trade was laid open upon the ſame terms. As the united privileges of the company were not ſufficient to counterbalance the various diſadvantages under which all freſh inſtitutions labour, they obtained, in 1682, the excluſive management of the colony of Surinam, for the trifling ſum of 260,000 florins paid to the ſtates-general. This grant was accompanied by certain conditions, framed with the manifeſt view of preventing the abuſes common to trading corporations. Under theſe reſtrictions, the company was not able to defray the expence of the original purchaſe-money paid for the charter; and, therefore, in the next year, one-third ſhare was ſold to the city of Amſterdam, and another to the rich family of Sommelſdyk, reſerving the remaining third to themſelves. Theſe three coproprietors have ſince continued to form a ſociety or partnerſhip, under the name of the "Surinam Company," regulated by the charter originally granted to the Weſt India company. Except in the government of Surinam, this aſſociation has had no connection with the Weſt India company, which, of courſe, continued to furniſh negroes to the ſettlement, in its capacity of African company, until the year 1730.

The progreſs of the dividends and prices of Weſt India ſtock will enable us to judge concerning the proſperity, not only of the Surinam ſociety, but alſo of the concerns of the Weſt India company. The average dividend in ten years, ending 1690, was $2\frac{2}{5}$ per cent.; and from 1773 to 1779 incluſive, nothing at all was divided. The actions have never been at par; their price has varied from $92\frac{1}{2}$ to 18 per cent. ſince the year 1723. The average price during ten years, ending 1732, was about $81\frac{1}{2}$ per cent. During ten years, ending 1779, it had fallen to $32\frac{4}{5}$ per cent. The ſettlements of Eſſequibo and Demerary have been always under the charter of the Weſt India company, as well as Surinam, and governed in the ſame manner. Berbice, though within the company's charter, owed its origin to the ſpeculations of the family of Van Peere; and all the cultivated part of the colony belonged to them. In 1678 they obtained a perpetual grant of it from the company, which was confirmed in 1703; and when the French attacked it in 1712, the colony bought them off with a conſiderable compoſition. The money was paid by their great mercantile houſes, and one fourth of it by the Van Feeres, who thus transferred three-fourth ſhares of the colony to the other merchants as co-proprietors; and the four houſes together formed a copartnery or company at Berbice, adminiſtered exactly in the ſame manner with the Surinam ſociety. The proprietary governments of North America differed from the company adminiſtrations of Guiana in many important particulars. They were the conſequence of large and thoughtleſs grants, made by the court to favourites, of waſte and uninhabited lands. As the Britiſh colonies were ſubſervient to the legiſlature of the mother-country, the Dutch colonies owed the ſame allegiance, not to the ſtates-general, but to the proprietors. The ill ſucceſs of the Weſt India company furniſhes an uſeful example of the manifold evils of company government. This company muſt of late have been annihilated by the capture of all their ſettlements.

Company, *Dutch North*, has no excluſive privilege; the advantage of its patent being of another kind, and very conſiderable.

There are alſo, in Holland, companies for the Baltic ſea, the fiſhery of Nova Zembla, Davis's Streights, and Greenland: yet none of their fiſheries are interdicted to private traders; all the difference between theſe and the companies conſiſting in this, that the former may not go aſhore to cut their fiſh in pieces, and melt their lard: but muſt bring their luggage to Holland.

Company, *Dutch Levant*. In ſtrictneſs, there is no Levant company in Holland: but the commerce of the private traders is ſo conſiderable, that the ſtate has taken the regulation thereof on itſelf.

To this end, they have eſtabliſhed a chamber of direction at Amſterdam, compoſed of ſix deputies, and a regiſter; who, under the burgomaſters, take care of every thing relating to the commerce of the Mediterranean; eſpecially that of Smyrna and Conſtantinople.

This company names the conſuls, appoints the number and ſtrength of convoys, terminates differences among the traders, and has alſo a right, on occaſion, to add new regulations to the old ones; though thoſe be of no force, till confirmed by the ſtates general.

Company, *French Eaſt India*, was eſtabliſhed in 1664, with an excluſive privilege to trade for fifty years in all the ſeas of the Eaſt Indies and South Sea; no adventurer to be admitted without a thouſand livres in ſtock; and foreigners, who have twenty thouſand livres in ſtock, to be reputed regnicoles.

The patent grants them the iſland of Madagaſcar; and the king to be at one fifth of the expence of the three firſt armaments, without intereſt; the principal to be refunded in ten years: or, if the company finds it loſes on the whole, the loſs to fall on the king's ſide.

The capital fund of the company, which was moſtly furniſhed by the king, was ſeven or eight millions of livres, but was to have been fifteen millions.

In effect, though no means were wanting to ſupport the company, yet it ſtill drooped, and ſtill ſtruggled; till, having ſubſiſted ten years without any change in its form, and being no longer able to diſcharge its engagements, there were new regulations concerted, but to little purpoſe. At length, things not being diſpoſed for a new Eaſt India company, nor much good to be expected from the old one, in 1708, the miniſtry allowed the directors to treat with the rich traders of St. Malo, and reſign to them their privilege under certain conditions. In the hands of theſe laſt, the company began to flouriſh.

Its chief factory was at Pondicherry, on the coaſt of Coromandel; this was the reſidence of the director-general; the other factories were inconſiderable. The merchandizes which the company brought into France were, ſilks, cottons, ſpices, coffee, rice, ſalt-petre; ſeveral kinds of gums and drugs, wood, wax, printed calicoes, muſlins, &c. The trade was laid open in 1769, which ſoon reduced the company to a ſet of mere holders of the government funds. A new company was eſtabliſhed in 1785 with the privilege of an extenſive trade to all parts of the Eaſt Indies, except the Iſle of France and its dependencies. This exception muſt have prevented the company from ſucceeding; but the experiment had ſcarcely been made when the trade was again laid open by the national aſſembly in 1790. As for the other French companies, ſuch has been the ſtate of the country, they are all, we preſume, extinct; and it is needleſs to give any account of them. Such were the *French Weſt India company*, eſtabliſhed in 1664, and poſſeſſing by their charter the property and ſeigniority of Canada, Acadia, the Antilles iſland, the iſle of Cayenne, and the Terra Firma of America, from the river of the Amazons to that of Oroonoko; with an excluſive privilege for the commerce of theſe places, as alſo of Senegal, and the coaſts of Guinea, for 40 years, on condition of paying half the duties; but in 1674 the grant was revoked, partly on account of the poverty of the company, and partly becauſe it had anſwered the purpoſe of its eſtabliſhment by recovering the commerce of the Weſt Indies from the Dutch:—the *French Miſſiſſippi company*, firſt eſtabliſhed in 1684, in favour of the chevalier de la Salle, who ſailed in ſearch of the Miſſiſſippi, but miſcarried with his colony, and came to an untimely death. He was ſucceeded by M. Hiberville. who found the Miſſiſſippi and ſettled a colony there; but this adventurer being poiſoned, M. Crozat obtained in 1712 the ſole privilege of trading to the French territories called Louiſiana, granted to him for 15 years:—*Company of the Weſt*, formed in 1717, when M. Crozat ſurrendered his grant before mentioned; and obtaining beſides every thing granted to the former company the commerce of beaver, enjoyed by the Canada company from the year 1706, but expiring in 1717:—*India company*, formed by a junction of the former company with that of Canada and with that of Senegal in 1718, and alſo by an union with the Eaſt India company, and with thoſe of China and St. Domingo, with the two firſt in 1719, and with the third in 1720;—the *Baſtion company*, ariſing from the aſſociation of two merchants of Marſeilles in the 15th century for fiſhing of coral in the gulf of Stora-Courcoury on the coaſt of Barbary, on the frontiers of Algiers and Tunis; ſo called from a ſmall fort called the "Baſtion of France;" built in 1561, but it ſunk in 1633;—and ſeveral other companies, which either fell of themſelves, or upon the expiration of their grants, and which it is therefore needleſs to mention.

Company, *Daniſh North*, was eſtabliſhed at Copenhagen in 1647. Its eſtabliſhments are very conſiderable in Norway; beſides which, it ſends veſſels to Waranger, whence they convey their merchandizes by land into the Daniſh Lapland; and by ſledges drawn by rein-deer into the Muſcovite Lapland. It alſo ſends others for Borandai and Siberia; where its agent takes them up, and conveys them, in like manner, on ſledges, to Panigorod, the capital of this part of the Muſcovite empire.

The commodities it ſends thither are rix-dollars, tobacco, and linens; it returns nothing but furs and ſkins.

Company, *Daniſh Iceland*, eſtabliſhed in the ſame year with the North Company, its chief factory is at Kirkebar, a large town in that iſland.

Company, *Daniſh Eaſt India*, eſtabliſhed in the year 1616, and inveſted not only with the excluſive privilege of trading to the Eaſt, but with the powers of civil and military adminiſtration; their chief factory was at Tranquebar. In 1634 this corporation was diſſolved, and another, with ſimilar privileges, ſubſtituted in its place. This alſo rapidly declined; and in 1686, a third inſtitution was tried for the ſame purpoſes; but this too failed in about 23 years; and the project was tried for the fourth time in 1732. The new company was provided with ample privileges and powers; and the poſſeſſion of theſe preſerved its exiſtence, and increaſed the profits of the ſtock-holder, at the expence of the country, and of the Indian ſettlements. In 1772 the charter expired, and was renewed under reſtrictions which proved ruinous to the proſperity of the company. In 1777, the king purchaſed the rights of the company, and the private trade began to flouriſh. When the charter was renewed in 1792 for 20 years, the private trade was rendered ſtill more free; all Daniſh ſubjects, and all foreigners were permitted to trade with the Indian ſettlements, upon receiving paſſports, either from Copenhagen or the Aſiatic ſeats of government, and upon condition of returning with the cargoes to Copenhagen.

Company, *Levant, of the Genoeſe*, eſtabliſhed in 1664, and confirmed by the Porte; notwithſtanding the oppoſition of the French. From 1670 this company has languiſhed and ſunk.

For a more particular account of the riſe and progreſs of moſt of the above mentioned and other companies, ſee "Anderſon's Hiſt. of Commerce."

Company, *New River*. This corporation conſiſts of a governor, deputy governor, treaſurer, and twenty-ſix directors, who hold a weekly board for appointing officers, granting leaſes, and redreſſing grievances. The projector of this canal for bringing water to London, with the aſſiſtance of king James I. and the corporation of London, is ſuppoſed to have expended 50,000*l.* upon it: the profits, which are divided into ſeventy-two ſhares, for the firſt thirty years admitted of little more than five pounds to each ſhare; but their value is much increaſed, and its original ſhares of 100*l.* are now eſtimated at upwards of twelve thouſand pounds each.

Company, in French *compagnie*. A certain number of people of war under the inſpection and command of a chief called captain. The number, however, is never fixed, but varies. In the guards, as in the artillery, a company conſiſts of 120 men. In the Auſtrian ſervice a company conſiſts of 200 men. A *compagnie d'ordonnance* was originally compoſed of fifteen companies of *gens d'armes* of a hundred *hommes d'armes* each. In former times the word *enſeigne* denoted the company of infantry, and the word *cornette* the company of cavalry. A company ſeldom conſiſts of fewer than 50 men. It generally has three or four ſerjeants, three or four corporals, and two drums.

Company, *Artillery*. See Artillery.

Company *of Muſicians*, in the city of Weſtminſter. See Charter.

Company, in *Sea Language*, denotes the whole crew of a ſhip, including her officers.

Company *of Ships*, is uſed for a fleet of merchant veſſels, who make a kind of charter-party among themſelves; whereby, under ſeveral clauſes and conditions tending to their common ſafety, they engage not to quit one another, but to defend each other reciprocally, during their voyage.

Theſe aſſociates, in the Mediterranean, are called conſerves. The chief conditions of the charter-party are, that ſuch and ſuch ſhall be owned admiral, vice admiral, and rear-admiral; and thoſe that bear no guns, ſhall pay ſo much per cent. of their cargo, for the expences of the admiral; that ſuch and ſuch ſignals ſhall be obſerved; that if they be attacked, the damages ſhall be reimburſed by the company in general, &c.

Company, *Rule of*, or *Fellowſhip*, in *Arithmetic*, is a rule whereby we diſcover or aſcertain the ſhare of the profits, or loſſes, belonging to the ſeveral partners, or aſſociates, in any enterprize, in proportion to the ſtock each contributed thereto, and the time that ſtock was in bank. See Fellowship.

COMPARATES, Comparata, in *Logic*, the terms or ſubjects of a compariſon; or the two things compared to each other.

COMPARATIONE—*Punctum ex* Comparatione. See Punctum.

COMPARATIONIS *Homogeneum*. See Homogeneum.

COMPARATIVE *Anatomy*. See Anatomy.

Comparative *Degree*, in *Grammar*, is an inflexion between poſitive and ſuperlative degrees; whoſe effect is, to ſet a thing above or beneath the level of another.

The Latins expreſſed their comparative degree by a particular termination of their adjectives, and particles; wherein they are followed by the Engliſh, though by few others of the modern languages.

The French form moſt of their comparatives by adding the particles *plus*, *moins*, and *auſſi;* the Italians, by *piu*, *meno*, &c. as the thing is to be raiſed, lowered, or equalled to another.

COMPARE, Val di, in *Geography*, an iſland in the Ionian ſea, anciently called Ithaca, noted for having been the country and kingdom of Ulyſſes.

COMPARISON, the relation of two perſons or things, conſidered as oppoſed, or ſet againſt each other, in order to find wherein they agree or differ; or wherein one has the advantage of the other.

Comparison *of Ideas*, an act of the mind, whereby it compares its ideas one with another, in reſpect of extent, degree, time, place, or any other circumſtances. This operation of the mind is the ground of relations.

Brutes ſeem not to have this faculty in any great degree: they have, probably, ſeveral ideas diſtinct enough; but cannot compare them farther than as to ſome ſenſible circumſtances annexed to the objects themſelves: the power of comparing general ideas, which we obſerve in men, they have not, as we may probably conjecture.

Comparison, in *Rhetoric*, is a figure, or rather place, in ſpeech, whereby two things are conſidered with regard to ſome third, which is common to them both.

Thus, Cicer. Topic. "Catoni licuit ſequi bellum civile, igitur et Ciceroni licebit." "It was allowed Cato to engage in the civil wars, therefore it may be allowed Cicero:" where, to engage in the civil wars is common to both.

There are three kinds of compariſon; the firſt *a majori*, *i. e.* from the major to the minor; as that of Cicero againſt Anthony, "Quid feceris domi tuæ, cum alienæ tam ſis inſolens?" Or that of Terence, "Quem feret, ſi parentem non fert ſuum?" From the ſame place, Ovid endeavours to appeaſe Cæſar.

> "Cur ego poſſe negem leniri Cæſaris iram
> Cum videam mites hoſtibus eſſe Deos?"

The ſecond, *à minori*, *i. e.* from the minor to the major: thus Cicero, "Majoris noſtri ſæpe mercatoribus, ac naviculatoribus injurioſius tractatis, bella geſſerunt; vos tot civium Romanorum millibus uno nuntio atque uno tempore necatis, quo tandem animo eſſe debetis?"

The third *à pari;* as when we contend, that what obtains in one thing, ought to obtain in another of the ſame kind: "It was a law that he who killed his father ſhould be ſewed up in a ſack, and thrown into a river; therefore, he who killeth his mother deſerves the ſame puniſhment."

> "Capto tuam, pudet heu, ſed capto, Maxime, cænam:
> Tu capis alterius; jam ſumus ergo pares.
> Mane ſalutatum venio, tu diceris eſſe,
> Ante ſalutatum: jam ſumus ergo pares," &c.
> Mart. lib. ii.

COMPARTIMENT, or Compartment, a deſign compoſed of ſeveral different figures, diſpoſed with ſymmetry, to adorn a parterre, a cieling, pannel of joinery, or the like.

The term of compartiment is alſo uſed in painting. The Turkiſh and Mooriſh paintings are only compartiments; the fine bindings of books are in compartiments, &c.

COMPARTITION, in *Architecture*, the uſeful and graceful diſtribution of the whole ground plot of an edifice, into rooms of office, and of reception, or entertainment. Compartition makes one of the great diviſions of the art of building.

COMPARTMENTS, in *Gardening*, are beds, plats, borders, and walks, laid out according to the form of the ground, and depend more on a good fancy, than on any ſet of rules, for their conſtruction. They are alſo ſometimes merely diverſities or knots of flower-gardens or parterres, of which there is an infinite variety, according to the fancy of the deſigner. Plain compartments are pieces of ground divided into equal ſquares and flower-beds, marked out by lines, and made of regularly equal length and breadth. Some allow to theſe ſquares borders of two feet broad, if the plot of ground be ſmall, and if larger of three feet, and edge the borders with box, or with upright hardy thyme; the alleys up between are to be laid with ſand or gravel, and kept clean weeded.

Compartment *of tiles*, is an arrangement of white and red tiles varniſhed, for the decoration of the covering of a roof.

Compartment, *alley of*. See Alley.

Compartment, in *Heraldry*, is the term for a partition in coat armour, when the arms of ſeveral families are borne by one, either on account of intermarriages or otherwiſe.

COMPASS, the *Mariner's* or *Nautical*. A period of about 500 years is now elapſed, ſince an admirable property of a natural production was either diſcovered by, or introduced amongſt, the nations of Europe. To the ſimple application of this remarkable property, mankind is indebted principally for the diſcovery of a new continent nearly equal to the old one, for an extenſive commerce between the moſt diſtant nations, and for an accurate knowledge of the ſhape and ſize of the world we inhabit. The *magnet* or *loadſtone* is the natural production, and its directive property forms the active part of that wonderful guide, the *mariner's compaſs*, or as it is more commonly called, ſimply the *compaſs*, probably from its moving in a circle, or from its compaſſing the whole horizon. Whatever relates to the hiſtory, the conſtruction, the uſe, and the defects, of this ſingular machine, is rendered extremely important by the curioſity, the intereſts, the ſecurity, and the wants of the human ſpecies.

The time when the attractive property of the magnet was firſt diſcovered, is by no means known. The opinions are various, but they are not eſtabliſhed upon hiſtorical documents of ſufficient accuracy and authenticity. Certain however it is, that mankind was acquainted with it at a very early period. Father Kircher, in his work, *De Magnete*, l. i. cap. v., endeavours to prove that the Hebrews were acquainted with the magnet's ſingular property of attracting iron; and from Plutarch it appears, that the Egyptians were not ignorant of it. Pythagoras, Ptolemy, Hippocrates, Empedocles, Democritus, Leucippus, Epicurus, and ſeveral other ancient philoſophers, knew and admired this wonderful property of the magnet. Thales and Anaxagoras were ſo ſtruck with it, as to imagine that the magnet had a ſoul; and Plato ſaid that the cauſe of its attraction was divine. Ariſtotle, Theophraſtus, Dioſcorides, Galen, and others, were likewiſe acquainted with this property of the magnet. But its directive property (*viz.* that property by which, if placed upon a piece of cork, or wood, &c. to ſwim on the ſurface of water, or if it be ſuſpended by a very flexible thread, ſo as to have ſufficient freedom of motion, it will conſtantly place itſelf in a certain ſituation with reſpect to the cardinal points of the world) does not appear to have been known to the ancients; and though the time of the diſcovery of this property is of a much more recent date, yet this too is involved in much doubt and obſcurity. It ſeems, however, that the uſe of this property, or (what amounts to the ſame thing) the uſe of the magnetic needle, was not known in Europe before the thirteenth century. The honour of its diſcovery has been much conteſted. The Spaniſh Jeſuit Pineda, and Kircher, affirm that Solomon knew the uſe of the compaſs, and that his ſubjects actually uſed it in their navigations. Plautus *in Mercatore*, act v. ſcene ii., has the following remarkable paſſage, *Huc ſecundus ventus eſt, cape modo vorſoriam.* Now ſome authors are of opinion, that by the word *vorſoriam* or *verſoriam*, is meant the mariner's compaſs; but ſome learned critics affirm that *verſoriam* or *verſorium*, meant a particular rope. And Dr. Lorimer is inclined to believe that it only meant the helm.

By the conſent of moſt writers, it ſeems that a certain Flavio, or John, de Gioja, or Giova, or Gira, a Neapolitan, who lived in the 13th century, has the beſt title to the diſcovery. Flavius Blond affirms that about the year 1302, the above-mentioned John de Gioja, a noble citizen of Amalphi, a town of Principato, in the kingdom of Naples, firſt diſcovered the mariner's compaſs; and he quotes the following verſe from Antony of Palermo, recorded by the Neapolitan hiſtorians, *viz.*

Primo dedit nautis uſum magnetis Amalphi.

The arms of the territory of Principato have, it appears, ever ſince been a mariner's compaſs. See *Collinas, et Frombellus de acus magneticæ inventore.* Inſt. Acad. Bonon. tom. ii. p. 3. p. 372.

Dr. Gilbert, an Engliſh writer of the 16th century, in his book *De Magnete*, affirms that Paulus Venetus (the Venetian Marco Paulo) brought the invention of the compaſs to Italy in the year 1260; having learned it of the Chineſe. But this cannot be true; for Marco Paulo did not ſet out for China before the year 1269, nor did he return before the year 1295 (ſee Purchas's Pilgrim, vol. iii.); whereas the directive property of the magnet, and the communication of that property to ſteel, was known in Europe before that time; though in all probability it was not uſed in navigation till ſome time after, which may very reaſonably be attributed to the clumſy mode of ſuſpending the magnetic needle, which muſt at firſt have been practiſed. Ludi Vertomannus aſſerts, that when he was in the Eaſt Indies, about the year 1500, he ſaw a pilot direct his courſe by a magnetic needle, faſtened and formed like thoſe now in uſe. And Mr. Barlow, in his Navigator's Supply, anno 1597, relates, that in a perſonal conference with two Eaſt Indians, they affirmed that, inſtead of our compaſs, they uſed a magnetic needle of about ſix inches in length, ſuſpended upon a pin in a diſh of white China earth filled with water, in the bottom of which there were marked two croſs lines to indicate the principal winds; the reſt of the diviſions being left to the ſkill of their pilots. But theſe two laſt obſervations, being of a date much poſterior to the uſe of the magnetic needle in Europe, conclude nothing with reſpect to its original diſcovery; ſince the uſe of that magnetic property might have been introduced into Aſia by ſome European.

P. Duhalde, in his "General Hiſtory of China," vol. i. in the annals of the Chineſe monarchy, ſpeaking of the emperor *Hoangti*, when he gave battle to *Tchi Yeou*, ſays, "He perceiving that thick fogs ſaved the enemy from his purſuit, and that the ſoldiers rambled out of the way, and loſt the courſe of the wind, made a carr, which ſhewed them the four cardinal points. By this method he overtook *Tchi Yeou*, made him priſoner, and put him to death. Some ſay there were engraven in this carr, on a plate, the characters of a rat and a horſe, and underneath was placed a needle to determine the four parts of the world. This would amount to the uſe of the compaſs, or ſomething very near it, being of great antiquity and well atteſted." And in another part of the ſame book, ſpeaking of certain ambaſſadors, he ſays, "After they had their audience of leave in order to return to their own country, *Tcheou Kong* gave them an inſtrument, which on one ſide pointed towards the north, and on the oppoſite ſide towards the ſouth, to direct them better on their way home, than they had been directed in coming to China. This inſtrument was called *Tchi Nan*, which is the ſame name as the Chineſe now call the ſea-compaſs by: this has given occaſion to think that *Tcheou Kong* was the inventor of the compaſs." This happened in the 22d cycle, above 1040 before Chriſt. Renaudot adduces ſtrong reaſons againſt the knowledge of the mariner's compaſs amongſt the ancient people of China, and of Arabia. See Kircher, *De Magnete, lib.* i. *cap.* v.

In the works of Claude Fauchet, entitled, *Recueil de l'origine de la Langue et Poeſie Francois, fol.* 555, there is a quotation from an old French poem, called *la Bible Guiot*, in which the mariner's compaſs is evidently mentioned. This ſame paſſage is likewiſe quoted by Muſchenbroeck, in his *Diſſertatio de Magnete*. The paſſage in which the compaſs is mentioned forms part of the abovementioned poem, contained in a curious quarto manuſcript of the 13th century, on vellum, belonging to the royal library at Paris, which was never publiſhed. The poem entitled *la Bible Guiot*,

Guiot, forms the firſt article of the volume; the author of which. *viz. Guiot de Provins*, as mentioned in the poem itſelf, was at the court of the emperor Frederic Barbaroſſa, held at Mentz in the year 1181, when the emperor's two ſons were knighted. See Chron. Abbot. Uſperg. p. 311.

Here follows this remarkable paſſage in its antiquated language, to which is ſubjoined a literal tranſlation made by a native of Provence.

Extract from la Bible Guiot.

Icelle eſtoile ne ſe muet,
Une arts ſont qui mentir ne puet,
Par la virtu de la manete
Une piere laide et brunete,
Ou il fers volenters ſe joint.
Ont regardent lor droit point
Puez c'une aguile lont touchie,
Et en un feſtu lont fiſhie,
En longue la mette ſens plus,
Et il feſtui la tient deſus;
Puis ſe torne la point toute
Contre leſtoile ſans doute,
Quant il nuis eſt tenebre et brune
Con ne voit eſtoile ne lune,
Lor font a laguille alumer;
Puiz ne puent ils aſſorer,
Contre leſtoile vers le pointe;
Par ce ſont il mariner cointe,
De la droite voie tenir;
C'eſt uns ars qui ne puet mentir.

Literal Tranſlation of the preceding.

This ſame (the pole) ſtar does not move, (and)
They (the mariners) have an art which cannot deceive,
By the virtue of the magnet
An ugly browniſh ſtone
To which iron adheres of its own accord.
Then they look for the right point,
And when they have touched a needle (on it)
And fixed it on a bit of ſtraw
Lengthwiſe in the middle, without more,
And the ſtraw keeps it above;
Then the point turns juſt
Againſt the ſtar undoubtedly,
When the night is dark and gloomy,
That you can ſee neither ſtar nor moon,
Then they bring a light to the needle;
Can they not then aſſure themſelves
Of the ſituation of the ſtar towards the point (of the needle?)
By this the mariner is enabled
To keep the proper courſe;
This an art which cannot deceive.

Francis Cabeus, a jeſuit of Ferrara, ſays, that the firſt thing he knows profeſſedly written reſpecting the directive property of the magnet, was an epiſtle of *Petrus Peregrinus Gallus*, about the latter end of the 13th century. A few years after, this epiſtle was diſguiſed by one John Taſnier, who publiſhed it in his own name, under the title of *Opuſculum perpetua memoria digniſſimum de natura et effectibus magnetis.* Some years ago, Mr. Senebier of Geneva ſent the following memorandum concerning this letter to Dr. Lorimer in London.

"*Epiſtola Petri Peregrini de Marcourt,*
Ad Sigerium de Foueancourt, Militem.
De Magnete."

"The work contains a deſcription of that ſtone, the means of finding the poles, its property of attracting iron, and proves that the part of the magnet which is turned to the north, attracts that which is turned to the ſouth. It then teaches the manner of employing the magnet in aſtronomy, and of playing tricks like thoſe of Comus. It deſerves to be remarked, that the author knew not that the magnet could be employed in navigation; for though he frequently ſpeaks *de ſtella nautica*, he never ſpeaks of the uſe that might be made of the magnetic needle in ſea voyages. *Vide Bibliotheca Bibliothecarum, fol.* 11. p. 1400. Catalogue of the manuſcripts in the library of Geneva, by Senebier, p. 207."

Amongſt the manuſcripts of the univerſity of Leyden, there is a volume containing ſeveral ſcientific tracts, one of which is a Latin letter of Peter Adſiger, on the properties of the magnet. It is, in fact, a little methodical treatiſe, divided into two parts, the firſt of which is ſubdivided into ten, and the ſecond into three chapters. This letter, which ſeems intended for the inſtruction of ſome particular friend, is dated in the year 1269. A few years ago, Mr. Cavallo obtained an exact copy of this curious letter, of which he inſerted very ample extracts, both in the original Latin and in Engliſh, in the ſupplement to the ſecond and third editions of his treatiſe on magnetiſm, from which it appears that the writer, at that early time, was acquainted with all the principal properties of the magnet. The following is the tranſlation of the moſt remarkable part of the abovementioned letter, which deſcribes the compaſs, and mentions the declination of the magnetic needle.

"Part II. Chap. 2. *On the conſtruction of a better inſtrument to anſwer the ſame purpoſe*, viz. *to find out the Azimuth of the Sun, the Moon, or any Star upon the Horizon.*

"In the preſent chapter, you will be informed of the conſtruction of another inſtrument of more certain effect: A veſſel muſt be made of wood, copper, or any other material, and let it be turned like a box of ſmall depth, and competently wide. Let a cover of ſome tranſparent ſubſtance, as glaſs or cryſtal, be adapted to it; and if the whole were made of ſome tranſparent matter, it would be ſtill better. A ſlender axis of copper or ſilver muſt be adapted to the middle of this veſſel, applying its extremities to the upper and lower parts of the box, *viz.* to the cover and to the box; the axis, however, muſt not be ſo firmly faſtened, as not to be capable of moving very freely. Two holes muſt be perforated in the middle of the axis, at right angles to each other, and an iron ſtyle, like a needle, muſt paſs through one of thoſe holes, whilſt another ſtyle of ſilver or copper paſſes through the other hole in a direction croſſing the iron one. The cover muſt firſt be divided into four parts, and each of theſe into ninety parts, agreeably to the inſtructions given concerning the other inſtrument in the preceding chapter, and upon it mark the north and the ſouth, the eaſt and the weſt, points; and let a ruler of ſome tranſparent ſubſtance, with ſights on its extremities, be adapted to it. Then place whichever part of the magnet you pleaſe, *viz.* the north or the ſouth, near the glaſs, until the needle be moved towards the ſaid magnet, and acquires the virtue from it; after which, the magnet being removed, the extremity of the needle will turn itſelf towards the pole. This being done, turn the box until one extremity of the needle remains directed towards the north part of the inſtrument, or the north part of the heaven; then turn the ruler towards the ſun in the day time, and towards the ſtars in the night time, after the manner mentioned in the preceding chapter. By means of this inſtrument, you may direct your courſe towards cities, and iſlands, and all other parts of the world, either on land or at ſea, provided you are acquainted with the longitudes and latitudes of thoſe places; for, if the town or iſland to which I intend to go is in a lower latitude than the place in which I am, I ſhall go ſtraight before me, towards that end of the ruler which is directed to the ſun or ſtar; but if the latitude of the place be greater, I ſhall proceed in the oppoſite way, *viz.* in the direction of the other extremity of the ruler. Obſerve, that the ſouth part of the needle, which is to be uſed as a guide, muſt be made to decline towards the weſt by one point; and this muſt be done by the declination of the north part towards the eaſt, becauſe the ſouth part of the inſtrument is deſtitute of diviſions."

"Take notice that the magnet, as well as the needle that has been touched by it, does not point exactly to the poles, but that part of it which is reckoned to point to the ſouth, declines a little to the weſt; and that part which looks towards the north, inclines as much to the eaſt. The exact quantity of this declination I have found, after numerous experiments, to be five degrees. However, this declination is no obſtacle to our guidance, becauſe we make the needle itſelf decline from the true ſouth by nearly one point and a half towards the weſt."

To this letter, Mr. Cavallo, in his treatiſe, ſubjoins the following obſervation. "It appears that the ſuſpenſion of the needle in the above deſcription, is a very clumſy one; and that the beautiful ſuſpenſion by a cap upon a pin, which is now univerſally uſed, was unknown to the author. It is likely, therefore, that for want of this ſuſpenſion, the needles at that time not moving ſufficiently eaſy, were not actually uſed in navigation, at leaſt in Europe, though the ſuſpenſion by means of a cap upon a pin, ſeems not to have remained long unknown after the date of this letter."

Sir G. Wheeler ſays, that he had ſeen a book of aſtronomy older than the year 1302, which mentions the uſe of the needle in aſtronomy, but not in navigation.

Gaſſendus adduces, as an argument of the French having been the inventors of the mariner's compaſs, that the north point of it is always marked with a flower-de-luce. Lib. x. Diog. Laert. t. I. p. 139. As for Goropius's pretence, that the compaſs muſt have been invented by the Danes, Dutch, or Germans, becauſe the 32 points on it are written and pronounced in the Dutch, or Teutonic language, it is hardly deſerving of a reply. Dr. Wallis attributes it to the Engliſh, for no other reaſon, but for its being called compaſs. Vincentius Bellaucenſis, and Albertus Magnus, who lived about the year 1245, alſo Lavinius Lemniſis, make mention of the direction of the poles of the magnet, as from a tract *de Lapidibus*, which had been attributed to Ariſtotle; but is, with more probability, ſuppoſed to have been written by ſome Arabian author, not long before their own time. This tract has been ſince loſt.

Notwithſtanding the foregoing remarks, it is ſtill very doubtful whether the uſe of the compaſs in navigation, or even the directive property of the magnet, was known by any people before the Europeans, in or about the 13th century; and it appears, that in the ſame century, or ſoon after, the above-mentioned Neapolitan, Flavio, or John de Gioja, if not the original diſcoverer, was at leaſt the firſt who uſed the mariner's compaſs, or conſtructed it for the uſe of veſſels in the Mediterranean.

The principle of the conſtruction of the compaſs is extremely ſimple. A magnet, or a piece of ſteel that has been rendered magnetical by means of natural or artificial magnets, muſt be freely ſuſpended, ſo as to be able to move without obſtruction; for ſuch magnet or piece of ſteel will, in that caſe, direct itſelf to certain parts of the world, which will of courſe indicate to the obſerver the direction of any other place, provided its ſituation on the ſurface of the earth be known. Suppoſe, for inſtance, that you are at ſea near Portſmouth, and wiſh to go towards Newfoundland, which lies to the weſt. By looking at the magnetic piece of ſteel or magnet, one extremity of which looks nearly towards the north, and turning your face to that part of the world, you proceed towards your left hand, at right angles to the direction of the needle; fot in that direction Newfoundland is to be found. And after the ſame manner, you may proceed in any other direction. Such is the ſimplicity of the principle; but the practical application of it, eſpecially in the preſent accurate mode of conſtructing inſtruments, and of making obſervations, requires a great degree of mechanical nicety, and a conſiderable degree of attention to a variety of circumſtances, upon which the accuracy of the inſtrument, and its various applications, abſolutely depend. On account of thoſe particulars, and in conſequence of various contrivances made at different times, the compaſs or magnetic needle has undergone innumerable alterations, both in ſhape and ſize; and every kind of conſtruction is attended with peculiar advantages, as well as defects; the moſt eſſential of which we ſhall endeavour to point out in the ſequel. From its various uſes, the compaſs has obtained different names and different forms. Theſe are reducible to the four following ſpecies, *viz.* 1. The *land compaſs*, which is uſed either for the pocket, or is adapted to theodolites, to celeſtial and terreſtrial globes, &c.; 2. The *ſteering compaſs* for the uſe of veſſels at ſea. 3. The *azimuth compaſs*, which ſerves to find the ſun's or ſtar's azimuth, whence the actual or true direction of the magnetic needle may be aſcertained (this ſeldom being due north and ſouth); and, 4. The *variation compaſs*, which, being ſituated in a proper place on land, ſhews the daily variation of the magnetic needle from its ordinary direction. See MAGNETICAL *Declination*, and MAGNETICAL *Variation*.

A common ſewing needle rendered magnetical, and ſimply laid upon water, or faſtened to a cork, or ſtraw, &c. and ſo laid upon water, in a glaſs, or earthen or wooden cup; or elſe ſuſpended by a very flexible thread, which muſt be faſtened to its middle, forms a ſimple but imperfect compaſs; and ſuch, in all probability, was one of the firſt modes of conſtructing the compaſs, whence the magnetized ſteel, wire, or bar, has, ever ſince, been called the magnetic needle. The defects of the laſt-mentioned conſtruction are too evident to need any particular remarks. The needle laid upon water is continually running to the ſides of the cup, the water is liable to be ſpilt, or if a thread be uſed, the ſtiffneſs of it will always influence the action of the needle. To avoid theſe inconveniences, an excellent contrivance was ſubſtituted. It is a conical cavity made in the middle of the needle or ſteel bar, as ſhewn in *Plate, Magnetiſm, fig.* 1. the open of which reſts upon a pointed wire *a*, which enables the needle to move with the greateſt freedom imaginable. The open of this cavity ſhould come as near as poſſible to the upper ſurface of the needle, or rather a little above it, as in *fig.* 2. in which caſe the upper ſurface of the middle part of the needle is left a little more elevated than the reſt. But in order to avoid any irregularity in the ſhape of the needle, as well as any difficulty in the mechanical formation, the needles are moſtly pierced quite through, with a pretty large hole; a piece of hammered braſs is rivetted into this hole, and the conical cavity is made into the braſs, ſo that the open of it may ſtand even with, or very little above, the upper ſurface of the needle. The upper part of the wire upon which the needle reſts, is generally made of hard ſteel, whilſt the lower part is made of braſs. This conſtruction anſwers very well for a conſiderable length of time; yet, by continual rubbing, a ſmall prolongation or irregularity of the cavity, is at length produced, which will in ſome degree obſtruct the free motion of the needle; hence, in the beſt needles, the upper part of the above-mentioned cavity is formed in a piece of agate, which is not in the braſs piece, as ſhewn in *fig.* 3. where AB is the needle, *c d* the braſs piece rivetted in a hole in the middle of it, and *e* is the piece of agate. The needles thus conſtructed are ſaid to have an agate cap. The defect to which thoſe agate caps are ſubject, is, that on account of the hardneſs of the ſtone, the cavity in it ſeldom runs to a point; the conſequence of which is, that the pin which ſupports the needle is apt to ſhift from one part of the agate cap to another, and of courſe the centre of the needle cannot always coincide with the point of ſuſpenſion.

The forms of the needles have likewiſe been very numerous. Some are ſlender and long, others broad and ſhort; ſeveral needles of the common ſort are made broad towards the end, but tapering towards the middle, or they terminate in two very ſharp points. Sometimes that extremity of the needle, which points towards the north, is formed like a croſs; but the moſt objectionable of all, are thoſe which conſiſt of two wires, and may be frequently met with on board of merchant ſhips. Two pieces of ſteel wire, each bent in the middle ſo as to form an obtuſe angle, and when fixed under the card, in the centre of which a braſs cap is faſtened, form a lozenge. All thoſe ſhapes may, in great meaſure, anſwer for common purpoſes; but they are far from being accurate or regular in their performance, the reaſon of which is, that a piece of ſteel of irregular form generally has more than two magnetic poles; almoſt every corner or protuberance being a ſouth or north magnetic pole; in conſequence of which the axis of the needle never coincides with its magnetic axis, the latter of which changes its ſituation in proportion as ſome of the above-mentioned poles become ſtronger or weaker than the reſt; and this is continually the caſe.

In order to avoid every irregularity of ſhape, and even the perforation, needles, for certain purpoſes, have been ſuſpended in the following manner: A B (*fig.* 4.) is the magnetic needle of a parallelopipedal form, which is faſtened to a piece of braſs C E D. In the middle of this piece of braſs at *g*, there is a ſmall conical cavity, wherein an agate cap is ſet. In order to ſuſpend this needle, a bar F H (*fig.* 5.) of braſs, or copper, or wood, is made faſt to the box K L.; in the middle of this bar a ſhort pointed wire is fixed, which, when the bar is made to paſs through the braſs piece C E D of *fig.* 4. *viz.* through *g*, enters the agate cap, and ſupports the needle. *Fig.* 5. repreſents the whole together, where F H is the bar faſtened to the box, A I B is the braſs piece, ſeen lengthways, or in the direction of the needle, which paſſes through the hole A B, and moves below the bar F H. It is evident that in this conſtruction the needle cannot turn quite round, conſequently this ſort of ſuſpenſion is not uſeful for navigation.

The Chineſe method of ſuſpending the magnetic needle is exceedingly ingenious (ſee *fig.* 6 and 7.), the firſt of which repreſents a ſection of this ſuſpenſion as viewed in the direction of the needle; and the ſecond exhibits a lateral view of the ſame. The letters refer to the ſame parts in both figures. I is a braſs cap very thin and light, and towards the edge of it there are two holes, oppoſite to each other. B B is a very ſlender ſlip of braſs, the upper part of which A, is ſhaped like a ring, through which the needle C D paſſes. The extremities of this ſlip of braſs go through the holes in the lower part of the cap, and are faſtened to it by being turned over its edge. The magnetic needle C D conſiſts of a cylindrical ſteel wire about an inch long, and not above a fortieth part of an inch in diameter; having its northern extremity only painted red by way of diſtinction. All this is ſupported by the pin E, which is faſtened to the bottom of the box, and upon which it moves very freely. In this conſtruction the needle is above the point of ſuſpenſion; yet the centre of gravity of all the three pieces (*viz.* cap, needle, and ſlip of braſs) taken together, is below the point of ſuſpenſion, which prevents the cap, &c. falling off from the pin when the compaſs is fixed in an horizontal poſition; but to prevent the cap with the needle being ſhook off by any ſudden jerks, or by inverting the inſtrument, there is a very thin braſs plate fixed to the box, a ſection of which is indicated by F G. It has a hole through the middle, which, being ſmaller than the diameter of the aperture of the braſs cap, prevents its falling off. It appears, from a variety of experiments, that the perforation through the magnetic needle is not attended with any bad conſequences. The external ſhape of the needle requires to be formed with greater attention, this being more apt to produce a multiplicity of poles. A very broad needle ſeldom has its magnetic axis coinciding with the axis of its figure. A very ſlender and long needle almoſt always has more than two magnetic poles. There is a certain breadth, proportionate to the length of a needle, which is leſs ſubject to an irregular diſpoſition of the magnetical virtue; this proportion, however, cannot be accurately determined. The little ſwelling generally left about the middle of the magnetic needles in order to give them ſtrength, where the perforation for the cap would otherwiſe weaken them, has not been found to produce multiplicity of poles, provided it be made ſmooth and free from corners. The lengths of the needles commonly uſed at ſea are from three to ſix inches, but thoſe that are uſed as variation needles are generally made longer, though they need not, however, exceed eight or at moſt nine inches. With reſpect to the ſubſtance of the needle, it muſt be obſerved that certain kinds of ſteel are more apt to acquire the magnetic virtue than others; but this muſt be determined by actual trial. The common ſort of magnetic needles are brought down to what is called by the workmen a blue temper, becauſe in that ſtate they are eaſily magnetized; but it muſt be obſerved that if in that ſtate they are eaſily magnetized, they are at the ſame time liable to loſe that power very eaſily; therefore the magnetic needles ought to be made quite hard; for in that caſe when they are once rendered magnetic, which is eaſily done, they will retain that power almoſt for ever after. The magnetic needles, though perfectly balanced before they are magnetized, will, after that operation, incline one of their extremities towards the horizon, which is in conſequence of the dipping property of the magnet. See MAGNETISM, and DIPPING *Needle*. Therefore after the communication of the magnetiſm, it becomes neceſſary to balance the needle again; but this muſt not be done either by grinding off part of that extremity of the needle, or by adding a fixed weight to the oppoſite extremity of it, becauſe the quantity of that dipping varies according to the change of ſituation on the ſurface of the earth. The beſt way of adding this weight is by placing a ſmall piece of braſs on one arm of the needle, capable of being ſlid nearer to, or farther from, the centre of the needle, by which means the balance of the needle when loſt may be eaſily reſtored. Upon all theſe conſiderations, a needle of the beſt form and ſize is exhibited at *fig.* 8. and 9.; the former of which repreſents a vertical, and the latter a lateral, view of it. A D is the needle of hard ſteel, C is the agate cap ſet in a piece of braſs, B a mark made on that extremity which points towards the north, in order to diſtinguiſh it from the other, and E is the piece of braſs which may be ſlid upon the arm C D, for the purpoſe of balancing the needle.

The ſhapes and ſizes of the compaſſes uſed upon land are very numerous; ſome being of the uſual ſize of a watch ſeal, and they are actually fixed in ſuch ſeals; others are of the ſize, and externally in the form of a pocket watch; others again are made in a wooden box, ſquare on the outſide, but circular within; ſome are of a larger ſize, in a braſs box. Sometimes a little ſun-dial is affixed to ſome compaſs boxes, and ſo forth. But though the ſhape be different, the principle of the conſtruction is the ſame in them all. The box, whether of wood, or braſs, or ſilver, or other ſubſtance, muſt have no particle of iron or ſteel in its conſtruction; and even the braſs, when that metallic ſubſtance is uſed, muſt be tried by preſenting the extremity of a very delicate magnetic needle to every part of it; for if any attraction be obſerved, that braſs muſt be rejected, otherwiſe the needle would not move with ſufficient freedom. Braſs is frequently magnetical, eſpecially after being hammered, which is generally done by the workmen, for the purpoſe of rendering it hard. A pin of hard ſteel is fixed in the centre of the box, upon the point of which the needle reſts; and a glaſs plate covers the cavity. This glaſs plate reſts upon a ſhoulder, and ſtands very little above the piece C (*fig.* 9.), ſo as not to touch that piece, whilſt at the ſame time it prevents the needle's falling from over the pin. In ſeveral of the compaſſes a little piece of wire with a button is affixed to the box, which is formed ſo as to ſtop the motion of the needle when the compaſs is not intended to be in action, as when it is carried in the pocket, &c.

The friction which muſt naturally take place in cleaning the glaſs cover of a compaſs, frequently excites its electricity, in which caſe the needle is attracted more or leſs by the glaſs, and its free motion is thereby partly or entirely obſtructed, Phil. Tranſ. N°. 480. p. 243. This inconvenience may be removed by paſſing a wet finger in various directions over the ſurface of the glaſs. Few needles of land compaſſes are furniſhed with cards like thoſe which are uſed at ſea. In general the principal points of the horizon are marked in the bottom of the box, and a divided circle is added to the box, ſo that the edge of it may be even with, and ſo near as almoſt to touch, the extremities of the needle.

The compaſſes uſed at ſea for aſcertaining and directing the courſe of veſſels, differ from the former principally by their having a circular card, whoſe diameter is equal to the length of the needle, fixed upon the needle, ſo as to turn with it, and by the box being ſet in a mechaniſm on four croſs centres, called gimbals, the office of which is to keep the compaſs box always in an horizontal poſition, whilſt the external box moves with the ſhip, as the latter rolls and pitches. This conſtruction will be eaſily underſtood, by obſerving *fig.* 10, which exhibits a ſteering compaſs as viewed by an eye placed perpendicularly over it. A B C D is the external wooden box, which is faſtened to and moves with the ſhip, E F is a braſs circle having two pivots or axes, G, H, which turn in two holes in the oppoſite ſides of the wooden box; *i o*, in the compaſs box, which is likewiſe furniſhed with two pivots or axes, *r*, *u*, and theſe turn in two holes made in the braſs ring F E. Now as the direction of theſe laſt pivots, *r*, *u*, is at right angles to the direction of the pivots, G, H, it will be eaſily underſtood, that in whatever direction the veſſel, and the box A B C D, which is fixed to it, may incline, the compaſs box, *i o*, remains always in an horizontal poſition, for it will turn either upon the pivots, *r*, *u*, or upon the pivots, G, H. K is the card which is fixed to the magnetic needle and moves with it, under the glaſs cover, through which it may be diſtinctly ſeen. The outer edge of this card is divided into 360 degrees, and within the circle of thoſe diviſions it is again divided into 32 equal parts or arches, called *the points of the compaſs*, or *rhumbs*. Theſe rhumbs are uſually divided into quarters. Their names, beginning from the north point, and going all round, are as follow: the letters ſtanding N, for north; E, for eaſt; S, for ſouth; and W, for weſt.

The conſtruction which has been more generally uſed in the royal navy, is an improvement of the late Dr. Knight, a gentleman of very extenſive knowledge in magnetiſm. In this conſtruction the weight of needle, card, &c. is removed conſiderably below the point of ſuſpenſion or centre of motion, by the addition of a braſs circle, whoſe diameter is equal to that of the card, which is made very thin. This ring being fixed below the card, and the needle above it, the centre of gravity of the whole comes low enough to admit of the cap being ſituated below the needle; hence the needle needs not be perforated. This needle is a perfect parallelopiped. The *figs.* 11 and 12 repreſent the lower and upper parts of this (Dr. Knight's) card, needle, &c. about one half of the real ſize. A B is the needle, and C repreſents the upper part of its cap, ſituated below it. The under part of the cap is ſeen at G; A D D B is the card. The braſs edge, or circle, is repreſented by F E O, and is faſtened to the extremities of the needle, (the card being interpoſed) by means of two ſcrews. H, I, are two ſliding weights to balance the card.

A few years ago another ſort of conſtruction was contrived by Mr. K. M'Culloch, for which he obtained a patent. The *figs.* 13 and 14 repreſent this compaſs, the former being a ſection, and the latter a perſpective view of it. In this compaſs, both the compaſs-box and the needle, with the card, are ſuſpended upon points, the extremities of which come very near to each other; which conſtruction keeps them horizontal without any gimbals, as will be eaſily manifeſted by the following deſcription. *Fig.* 13. A *a a a a*, is the common wooden box, with its lid; *b b* the braſs compaſs box; *c c* the glaſs cover to it; *d d* the hollow conical bottom; *e* the prop, upon which the compaſs is ſupported inſtead of gimbals; the ſpherical top of which is finely poliſhed, and the apex of the hollow cone is fitted to receive it; *f f* is a quantity of lead run round the bottom and cone of the compaſs box, to balance and to keep it ſteadily horizontal; *g g* is the card, and the magnetic needle, bent in ſuch a manner as to bring the point of the conical pivot, on which it moves and is ſupported, very near to the centre of gravity, as well as to the centre of motion; *h h* are two guards, which, by means of the two pins *i*, *i*, affixed to the compaſs-box, prevent its turning round, and deceiving the ſteerſman. In *fig.* 14, both the lid and the front of the box are removed; *h h* are the guards; *b* the compaſs-box, and *e* is the prop which ſupports the box.

The greateſt inconvenience that attends the uſe of the compaſs at ſea is the irregularity of motion induced by ſhocks of ſudden impulſes. In thoſe caſes the veſſel is ſuddenly moved out of its direction, and the card of the compaſs is ſet a vibrating for a conſiderable time, during which the ſteerſman is unable to regain his courſe. Several methods have been tried for the purpoſe of removing this inconvenience, and the above deſcribed compaſs of Mr. M'Culloch's contrivance was ſuppoſed to accompliſh this end in a conſiderable degree; but the experience of ſome years ſhews that this is not the caſe. The leaſt ſkilled ſeamen do not like the needles of their compaſſes too powerfully magnetized, becauſe, they ſay, then the needles are not ſteady. The fact is, that when the needle is not ſtrongly magnetic, it follows the irregularities of the ſhip's motion in a great degree; which renders it apparently more ſteady; but the very ſame cauſe which enables it to follow the irregular motion of the ſhip, prevents at the ſame time its placing itſelf in the magnetic meridian. With the ſame degree of impropriety, ſome perſons have endeavoured to prevent the irregular ſhocks or vibrations of the magnetic needle by increaſing the friction between the cap of the needle and the pointed wire which ſupports it. Sometimes pieces of paper, like wings, have been ſtuck to the lower ſurface of the card, which, by offering a reſiſtance againſt the air in the box, check in ſome meaſure the irregular movements of the card. In the year 1779, Dr. Ingenhouſz preſented a paper to the Royal Society, which is publiſhed in the 69th vol. of the Philoſophical Tranſactions, and in which he deſcribes ſome experiments, made by magnetic needles in water, where he found that a ſtrong magnetical needle placed itſelf in the magnetic meridian, nearly as well under water as in the open air, and that by the reſiſtance of the medium, much of its too great verſatility was taken away. In conſequence of thoſe experiments the Dr. propoſed to encloſe the magnetic needle in ſome fluid for the uſe of veſſels. "Common water," he ſays, "would be, perhaps, the beſt medium for theſe different contrivances, if ſteel was not ſo eaſily ruſted by it, and if in cold weather water was not ſo apt to freeze; therefore, I think, that ſome of the thinneſt expreſſed oils would anſwer the purpoſe better. The glaſs baſon containing ſuch a compaſs ſhould be full of the liquid to the cover, to obſtruct undulating motions." But though this propoſal appeared at firſt very promiſing, and ſome eminent philoſophical inſtrument-makers were much ſtruck with it; yet it does not appear that it was ever adopted.

The uſe of the compaſs in general is to direct a perſon along any required track, which makes a known angle with the direction of the magnetic needle; and this renders the compaſs applicable to a variety of purpoſes; thus it guides travellers in deſerts, as in Arabia, in the woods of America, &c.; it enables the navigator to proceed in any required track; it is highly uſeful to the miner, by ſhewing the direction of ſubterranean places; it ſerves for meaſuring horizontal angles; hence it is uſeful in land-ſurveying, taking plots, finding bearings in dialling, &c. And laſtly it ſerves to ſet ſun-dials, and other aſtronomical inſtruments when no great accuracy is required. The application of the compaſs to thoſe purpoſes is ſo very obvious, as not to require any farther illuſtration. But for ſome of theſe purpoſes, ſights muſt be applied to it, as in the azimuth compaſs.

The *azimuth compaſs* is a ſteering compaſs of any of the above-mentioned conſtructions, to which two ſights are adapted, through which the ſun is to be ſeen, in order to find its amplitude or its azimuth, whence the declination of the magnetic meridian from the true or aſtronomical meridian may be determined; thoſe two meridians ſeldom coinciding. At preſent (1807) in London, the declination of the magnetic needle is about 24° 9′ weſt; that is, the northern extremity of the magnetic needle, points to a part of the heavens, which makes an angle of about 24° 9′ with the true North. But this declination is various at different times in the ſame place, as well as at different places at the ſame time.

The more uſual ſort of azimuth compaſſes is repreſented in *fig.* 15, where F, G, are the ſights, or ſight vanes, in one of which, G, there is an oblong aperture, with a perpendicular thread or wire through its middle; and in the other ſight, F, there is a narrow perpendicular ſlit. A thread or wire, H I, is ſtretched from one ſide of the edge of the box to the other. The ring A B of the gimbals reſts with its pivots on the ſemicircle C D, the foot, E, of which turns in a ſocket, ſo that whilſt the box, K L M, remains ſteady, the compaſs may be turned round, in order to place the ſights, F, G, in the direction of the ſun, or other celeſtial object. The pivots of the gimbals of this, as well as of the ſteering compaſs in general, ſhould lie in the ſame plane with the point of ſuſpenſion of the needle or card, for the purpoſe of avoiding the irregularity of its vibrations as much as poſſible. In the inſide of the box there are two lines drawn on its ſides perpendicularly down, from the points where the thread, H I, touches the edge of the box. Theſe lines ſerve to ſhew how many degrees the north or ſouth pole of the needle is diſtant from the azimuth of the ſun; on which account the middle of the apertures in the ſight vanes, F and G, the thread H I, and the above-mentioned two lines muſt ſtand exactly in the ſame vertical plane. The uſe of the thread H I, which is ſometimes omitted in compaſſes of this ſort, is to ſhew the degrees between the magnetic meridian and the azimuth, &c. when the eye of the obſerver ſtands perpendicularly over it. On one ſide of the box of the azimuth compaſs, there generally is a nut or ſtop, which, when puſhed in, bears againſt the card and ſtops it; and this is done for the purpoſe of reading that degree, half degree, &c. of the card, which coincides with one of the perpendicular lines in the inſide of the box.

Mr. M'Culloch's azimuth compaſs is repreſented in *fig.* 16, where *b* is the compaſs-box, *h* one of the guards, *e* the prop, which ſtands in a braſs ſocket, and may be turned round at pleaſure, 1 is a braſs bar upon which the ſight vanes are fixed; 2, a dark glaſs, which moves up or down on the ſight vane 3; 4 is a magnifying-glaſs, which is alſo moveable on the other ſight vane; 5 is the nonius or vernier; 6 a ſlide for moving the vernier ſo as to ſtop the card in taking the azimuth; and 7 a double convex glaſs, through which the diviſions on the vernier may be read with accuracy.

In order to obſerve at ſea the magnetic amplitude of a celeſtial object (*viz.* its bearing by the compaſs when in the horizon) with the azimuth compaſs, place the inſtrument on a ſteady place, whence the horizon may be clearly ſeen; and looking through the ſight vanes of the compaſs, turn the inſtrument round, until the centre of the ſun's diſk, or other celeſtial object, may be ſeen through the narrow ſlit in one of the ſight vanes, exactly on the thread which biſects the other ſight vane; and at the inſtant that the centre of the celeſtial object, whether riſing or ſetting, is in the horizon, puſh the ſtop in the ſide of the box, ſo as to ſtop the card, then read the degree, half degree, &c. of the card, which ſtands againſt one of the perpendicular lines in the inſide of the box, and this is the magnetical amplitude ſought.—In this obſervation, ſome allowance muſt be made for the height of the obſerver's eye, above the level of the ſea. The true amplitude of the celeſtial object is an arch of the horizon contained between the eaſt or weſt points of the horizon, and that point of the horizon which the centre of that celeſtial object cuts in its riſing or ſetting. In order to find the true amplitude of the celeſtial object, the latitude of the place of obſervation, and the actual declination of that object, muſt be known; then ſay, as the coſine of the latitude is to radius, ſo is the ſine of the declination to the coſine of the amplitude ſought.

To obſerve at ſea the magnetic azimuth of a celeſtial object, (*viz.* its bearing by the compaſs when above the horizon), ſituate the inſtrument in a ſteady place, and looking through the narrow ſlit in one of the ſight vanes, turn the box round until the centre of that object appears to coincide with the thread in the ſlit of the other ſight vane, or till the ſhadow of that thread, when the ſun is obſerved, falls exactly along the line on the ſurface of the compaſs-box, and at that inſtant ſtop the card; then read the degree, &c. as above directed with reſpect to the amplitude, and thus you have the magnetic azimuth of that object.—The true azimuth of that object is an arch of the horizon intercepted between the north or ſouth point, and that point in which a plane paſſing through the zenith and the celeſtial object, cuts the horizon. In order to find this azimuth, the latitude of the place of obſervation, the declination of the celeſtial object and its altitude muſt be known; and ſince to determine the declination of the magnetical needle, this true azimuth of a celeſtial object muſt be taken at the ſame time that its magnetic azimuth is taken; therefore the altitude of that object muſt be taken with a ſextant, at the very inſtant that its magnetic azimuth is taken; *viz.* at the time the card is ſtopped; then proceed in the following manner: If the declination and latitude be both north or both ſouth, call the co-declination A; but if they be one ſouth and the other north, add 90° to the declination, and call the ſum A. Call the difference between the co-latitude and co-altitude B. Let the half of the ſum of A and B be called D; and the half of their difference be called C; then add together the four following logarithms, *viz.* the arithmetical complement of the logarithmic ſine of the co-latitude, the arithmetical complement of the logarithmic ſine of the co-altitude, the logarithmic ſine of D, and the logarithmic ſine of C. Half the ſum of thoſe four logarithms is the logarithmic ſine of half the azimuth ſought.

Now, having ſhewn how to find the true and the magnetical amplitudes as well as azimuths, we ſhall briefly add the method of determining from them, the declination of the magnetic needle for the time and place when and where the obſervations are made. Let the amplitudes, as well as the azimuths, be all reckoned from the north point, which is effected by ſubtracting the amplitude from 90° when it is on the northward of the eaſt or weſt points; or by adding it to 90° when it is ſouthward of the ſaid points. Then the magnetic amplitude is either ſmaller or greater than the true amplitude. When the magnetic amplitude is leſs than the true, and they are both on the ſame ſide of the north point, their difference is the declination of the magnetic needle towards the contrary ſide of the north point. But if they be on different ſides of the north point, then their ſum is the declination towards the ſame ſide with the true amplitude. When the magnetic amplitude is greater than the true, and they are on the ſame ſide of the north point, their difference ſhews the declination towards the ſame ſide. But if they be on different ſides, then their ſum is the declination towards the ſame ſide with the true amplitude. Thus, for example, if the magnetic amplitude is 80° eaſtward of the north point, and the true amplitude is 82° towards the ſame ſide; then the declination is 2° weſt. And if the magnetic amplitude be 76° eaſtward of north, whilſt the true amplitude is 5° weſtward of north, then the declination is 81° weſt. The ſame directions, *mutatis mutandis*, are to be followed for finding the declination from the magnetical and true azimuths.

Ever ſince the diſcovery of the declination of the magnetic needle from the true meridian, which appears to have been firſt obſerved by Columbus in his firſt voyage towards the continent of America, in the year 1492, the cauſe of that phenomenon has been earneſtly ſought after by inquiſitive perſons in the ſcientific world; and eſpecially when it was found that this declination varies continually, in a manner, which has not, as yet, been reconciled to any theory. The moſt promiſing method of inveſtigating the ſubject appeared to be that of obſerving attentively the daily, and even the hourly, variation of the declination, in order to diſcover, if poſſible, any period in it, or any dependance of it upon other natural phenomena. And in fact, the late ingenious Mr. Canton, who made numerous obſervations relative to the ſubject, found a periodical increaſe and decreaſe of the magnetical variation, in great meaſure correſponding with the temperature of the different parts of a natural day. For this purpoſe accurate compaſſes were fixed in various obſervatories, and the variation of the magnetic needle has been obſerved, at leaſt once every day, for a great many years; ſuch obſervations having frequently been inſerted in meteorological journals, and elſewhere.

The variation compaſs being intended to ſhew the daily variation of the magnetic needle upon land, is generally made longer than thoſe that are uſed at ſea; and, as it is not neceſſary to turn it round, the box generally is of an oblong form, ſo that the angular motion of the needle in it may amount to about 40° or 50°. The divided arches are either within the box, concentric with the point of ſuſpenſion of the needle; or out of it, on a frame, the particular conſtruction of which will appear from the deſcription of the variation compaſs of the Royal Society of London, which will be given preſently. When the divided arches are within the box, in which caſe a nonius is often placed on one extremity of the needle, the variation is known by obſerving the diviſion which coincides with the axis of the needle. In either conſtruction, it is evident that the beginning of the diviſions of the arch or arches muſt be placed exactly in the meridian of the place; or elſe its deviation from the meridian muſt be accurately known and allowed for in reading the degrees of magnetical variation. And it is almoſt ſuperfluous to add that ſuch compaſſes muſt be ſituated in very ſteady places, out of the influence of iron; ſo much ſo that it will be proper for the obſerver, when he examines the compaſs, &c. to take out of his pockets, keys, knives, or any other article of ſteel and iron; for otherwiſe theſe will ſenſibly alter the direction of the needle. We ſhall now ſubjoin the particular deſcriptions of two variation-compaſſes of the beſt conſtruction, *viz.* of that which is uſed at the Royal Society, and is deſcribed by the honourable Henry Cavendiſh, in the 66th vol. of the Philoſophical Tranſactions; and of that which was contrived by Mr. Cavallo, and is deſcribed in his "Treatiſe on Magnetiſm;" the former of which, being much larger, is well calculated for a fixed obſervatory, whilſt the latter is ſmaller, more compact, and may be eaſily fixed in any place.

Fig. 17, is a plan of the Royal Society's variation-compaſs. "In this inſtrument, the box which holds the needle is not fixed, but turns horizontally on a centre, and has an index faſtened to it, pointing to a divided arch on the braſs frame on which it turns; and the method of obſerving is to move the box, till a line drawn on it points exactly to the end of the needle; which being done, the angle that the needle makes with the ſide of the frame is ſhewn by the index. A B *b a* is the braſs frame, the ſides A B and *a b* being parallel: E*e* is a circular plate faſtened thereto, on which C D *d c*, the box which holds the needle, turns as on a centre; N*n* is the needle, the pin on which it vibrates being fixed in the centre of the plate E*e*; B*b* is the diviſion on the braſs frame; and G the index faſtened to the box, C D *d c*, furniſhed with a vernier diviſion; the diviſion and vernier being conſtructed ſo as to ſhew the angle which the line, F*f*, makes with A B, or *a b*. The inſtrument is placed in the meridian by the teleſcope, M *m*, the line of collimation of which is parallel to A B, and is pointed to a mark fixed due north of it. *Fig.* 18, is a vertical ſection of the inſtrument paſſing along the line F*f*; A B is the braſs frame; C D *d c* is the box which holds the needle; E*e* the circular plate on which it turns; N*n* is the needle; P and *p* are ſmall plates of braſs fixed to the ends of it, on each of which is drawn a line ſerving by way of index. Theſe pieces of braſs are raiſed to ſuch a height that their tops are on a level with the point of the pin on which the needle turns. The uſe of them is, that it is much eaſier obſerving this way, than when the lines, ſerving by way of index, are drawn on the needle itſelf, as by this means the inconvenience proceeding from one kind of vibration in the needle is avoided. S, and *s*, are two braſs plates, on each ſide of which is drawn a line, to which the index at the end of the needle is to point; there is alſo a line parallel to theſe, drawn on the bottom of the box; theſe three lines form the line, F*f*, in *fig.* 17. R is a double microſcope intended to aſſiſt us in judging when the index, P, points exactly to the line, F, that is, to the line drawn on the plate S. It is placed ſo that a wire, W *w*, in its focus, appears to coincide with this line; and in obſerving, the box is moved till the wire appears alſo to coincide with the index P. The cap in the centre of the needle is made to take on and off readily, and to fit on upon either face; ſo that we may on occaſion obſerve with the under face of the needle uppermoſt. The intention of inverting the needle is to ſhew whether the axis of the figure of the needle coincides with its magnetic axis.

The *figures* 19 and 20, exhibit a vertical view, and a ſection of Mr. Cavallo's variation-compaſs, and thoſe repreſentations are two thirds of the real ſize of the inſtrument. The letters of reference indicate the ſame parts in both figures. A B D is a braſs bottom with a circular braſs piece, *cei*, ſcrewed faſt upon it. F G H K is a rim likewiſe of braſs, that ſlides on the outſide of the circular piece *cei*, and to which the flat glaſs, M, is faſtened; ſo that when the rim is removed, the glaſs comes off with it. The ſhape of the needle is clearly indicated by the figures. It has a hole in the middle to receive the agate cap, which is burniſhed into a braſs ſocket, and is ſo ſituated into the needle, that the apex of its cavity does not riſe higher than the ſurface of the needle; hence the point of ſuſpenſion upon the pin, B, is even with the upper ſurface of the needle. By this means the pendulum-like oſcillations cannot diſturb the direction of the fine lines marked on the extremities of this needle. The upper and lower ſurfaces of this needle are quite alike, and the braſs ſocket, which contains the agate cap, is made ſo as to admit of the needle's being turned with either of theſe ſurfaces upwards. The hole in the middle of the needle is quite cylindrical, and ſo is the outſide of the braſs ſocket, which fits the ſaid hole exactly, but projecting a little way beyond the needle, has a ſcrew cut on that projection, upon which another circular piece of braſs is ſcrewed to fix it, as may be ſeen in *fig.* 20. It is evident, therefore, that when the laſt-mentioned piece of braſs is unſcrewed, the ſocket with the agate cap, may be put in on either ſide of the needle, and may be faſtened on the oppoſite ſide of it. By this means a great ſource of error may be avoided, namely what ariſes from the magnetical axis of the needle being not in the axis of its figure, which is frequently the caſe; for, if the direction of this needle be obſerved with one ſide of it upwards and then (the needle being turned) be obſerved again with the other ſide upwards; either the ſecond obſervation coincides with the firſt, and then we may conclude that the magnetical axis of the needle is truly in its middle; or the obſervations differ, and thence we ſhall know that the magnetical axis of the needle is not in the axis of its figure; but in this caſe we may have the real magnetic direction by taking a mean of the two obſervations; or we may thereby aſcertain, once for all, how much the line of direction of the needle deviates from its magnetic axis, which, when once aſcertained, becomes a fixed quantity to be either ſubtracted from, or added to any other obſervation."

"The upper ſide of the circular piece *cei* is ſilvered, and divided into degrees and half degrees; but thoſe diviſions, being too minute, are omitted in the figure. The bottom A B D has two projections, A and D, oppoſite to each other, and on each of their chamfered edges a line is marked, which, being drawn at the ſame time that the circle, *cei*, is divided by the circular dividing engine, coincide exactly with the commencement of the numeration of the degrees on the oppoſite ſides of the circle, from which places the degrees run on both ſides as far as 90°. The needle, therefore, which lies with its upper ſurface even with the divided circle, points to the ſame degree and part of a degree with both its extremities."

"We come now to deſcribe the method of meaſuring the parts of a degree on the circle, which is only divided into half degrees. This is obtained by means of the microſcope, *fig.* 21., which is furniſhed with one of my mother-of-pearl micrometers. (Phil. Tranſ. vol. 81.) The external conſtruction of the microſcope, and likewiſe the manner of placing it perpendicularly upon the compaſs box, are indicated by *fig.* 21; at N in *fig.* 19; and by the dotted lines at K, in *fig.* 20. P is a ſhort tube ſupported by the uprights R, R, the lower parts of which project horizontally. Theſe horizontal projections, O, O, are notched at Y, ſo as to fit the mouldings, H, K, of the rim F G H K, when the parts, O, O, reſt upon the glaſs. By this means the microſcope may be moved all round the compaſs-box, whilſt it keeps ſome of the diviſions of the circle always in the field of view. The body of the microſcope may be moved up and down in the tube P, in order to adjuſt it for diſtinct viſion. It conſiſts of the tube S S, into the upper part of which ſlides a ſhort eye-tube T, and at its lower extremity, H, a lens is faſtened. Two other lenſes are fixed into the tube T, which is about nine-tenths of an inch long, and within it; *viz.* exactly in the focus of the eye lens, the mother-of-pearl micrometer is ſituated. Thoſe three lenſes are all of the plano-convex ſort. The focus of the upper one is about four-tenths of an inch, and the focus of the ſecond and third is about ſix-tenths of an inch. The diviſions of the micrometer are 300ths of an inch, and when viewed through the microſcope, and the microſcope is placed upon the compaſs, 15 of them appear to be exactly equal to half a degree on the circle *cei*. But there is no need for thoſe diviſions to be exactly

300ths of an inch. It is ſufficient if they are nearly ſo, as, for inſtance, from about 280 to 320 in an inch; becauſe by pulling the tube T more or leſs out of the tube SS, and by moving the laſt mentioned tube up or down into P, the diviſions of the circle may be magnified more or leſs, till 15 diviſions of the micrometer appear to be exactly equal to the ſpace between any two contiguous diviſions on the circle; *viz.* to half a degree. When the microſcope has been once ſo adjuſted, it requires no farther alteration, excepting to be moved round the box until it comes over the end of the needle, in which ſituation the field of view appears as ſhewn in *fig.* 22, where the middlemoſt part is occupied by the micrometers 1, 2, 3, 4; the other large diviſions are the magnified diviſions of the circle, and W is the extremity of the needle, with its directive line pointing to ſome diviſion on the micrometer."

"Fifteen diviſions of the micrometer being equal to half a degree, or to 30′, it follows that each diviſion is equal to two minutes, and as it may be eaſily diſcerned whether the line on the end of the needle is directed exactly to one of thoſe diviſions or midway between two of them, therefore the direction of the needle in this compaſs may be read off to a ſingle minute. In order to obſerve the daily variation, when this compaſs is properly fixed, the microſcope need not be moved, becauſe its field of view takes in about two degrees, which is a much greater ſpace than the needle will go through in ten years time. In moving the microſcope round the box, care muſt be taken to place it ſo that the diviſions of the circle may appear to coincide with ſome of the long diviſions of the micrometer.—N. B. This microſcope inverts the objects; therefore what appears to be on the right hand muſt be underſtood to lie on the left, and *vice verſâ.*"

"In order to obſerve the real direction of the magnetic needle, or the daily variation, the compaſs muſt be placed ſo as that the two lines marked on the projections A and D, *fig.* 19, may coincide with a meridian line drawn upon a board, a ſtone, a block, &c. and then the degrees and minutes, to which the extremity of the needle is directed, will ſhew the required variation."

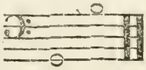
Having, in the preceding paragraphs, mentioned all the important particulars relating to the diſcovery, the conſtruction, and the uſe of one of the moſt remarkable, and the moſt uſeful, philoſophical inſtruments, we ſhall conclude by mentioning a deception which has ſometimes been offered to the credulous and unſkilled part of mankind. It is a compaſs, or a magnetical needle which was pretended to point due north and ſouth, without any variation at any time or place; and compaſſes apparently of this deſcription have actually been offered for trial and have even been ſent abroad. But upon examination it has been found either that the north and ſouth points of the card were not placed over the north and ſouth points of the needle; or that the needle, having been made purpoſely broad, had been magnetized ſo that the direction of its poles made an angle with the axis of its figure, juſt equal to the magnetical declination at that particular time and place. The conſequence of this artifice is, that though the needle may appear to have no declination at that particular time and place; yet at any other time, or if moved to another place where the magnetical declination is different, its direction will deviate from the true meridian. The declination or variation, like the attraction and repulſion, belongs to every piece of magnet, be it natural or artificial, and the magnetic needle is of the latter ſort; nor can, at the ſame time and in the ſame place, one needle point to one part of the heavens whilſt others point to a different part; provided they be freely ſuſpended, and be uninfluenced by iron or other magnets.

COMPASS *of voices*, in *Muſic*. In early times of counterpoint, human voices of different compaſs, occaſioned by age, ſex, and natural organ, were claſſed and divided into four diſtinct kinds, at the diſtance only of a third above each other, which the baſe, or F clef, placed from line to line, expreſſed. The loweſt of theſe was called the tenor, the next contratenor, motetus the third, and triplum the higheſt, or treble; of which term this was the origin.

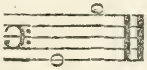
After this, about the middle of the fifteenth century, as different parts began to be multiplied, the ſcale received ſix diviſions: baſe, baritono, tenor, contralto, mezzo ſoprano, and ſoprano. The natural pitch of theſe is about three or four notes above each other, as their ſeveral clefs, which originally ſerved as barriers, will diſcover.

It ſeldom happens that a voice has more than ten real, ſteady, and full, natural notes, in its compaſs, without a mixture of falſet, which, being of a different regiſter, is eaſily diſcovered. The following are the names and uſual extent of the ſeveral ſpecies of human voice.

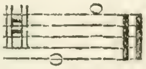
1. *Baſe.*



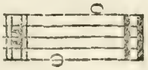
2. *Baritono.*



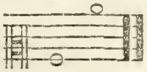
3. *Tenor.*



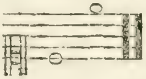
4. *Contralto.*



5. *Mezzo Soprano.*



6. *Soprano.*



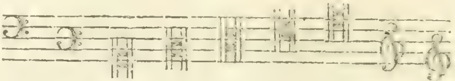
But as there are ſometimes baſe voices which go down to double F, and even lower; ſo there are in the treble, among modern vocal phenomena, ſingers that go higher than F in altiſſimo; which make the whole diapaſon of voices exceed four octaves. And there is at preſent (1802) in England, a German buffo ſinger with a baſe voice that goes down to double gammut in real muſical tones; and in falſet, up to G on the ſecond line in the treble. No public uſe was made of this extraordinary voice. He arrived in autumn, when no theatres were open, and remained but a ſhort time.

But though parts in choral muſic were multiplied, not only to ſix, but even thirty-ſix, before the cloſe of the fifteenth century; yet the general, and eſtabliſhed number, in the pope's chapel, by which probably all other choral ſervice was regulated, amounted to no more than four: cantus, altus, tenor, and baſe; which ſee ſeverally.

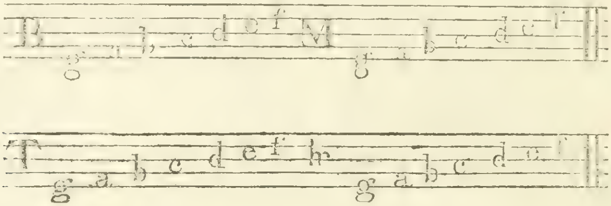
If it be aſked why ſo many clefs are uſed? It may be anſwered, to keep the melody of theſe ſeveral voices within the compaſs of the five line ſtaff; to prevent the perplexity of a great number of leger-lines, which in ſinging and playing at ſight, frequently alarm and embarraſs the performer.

Of all the expedients propoſed by ſpeculative and ingenious men, for the abolition of tenor clefs, the only one that ſeems practicable, and has the merit of great ſimplicity, was publiſhed in our own country in the time of Charles II. under the title of "An Eſſay to the advancement of Muſic, by caſting away the perplexity of different cliffs; and uniting all ſorts of muſic, lute, viols, violins, organ, harpſichord, voice, &c. in one univerſal character, by Thomas

Salmon, A. M. of Trinity College, Oxford." London, 1672. This book is well written, and, though very illiberally treated by Lock, Playford, and ſome other profeſſors, contains nothing that is either abſurd or impracticable; nor could I diſcover, ſays Dr. Burney, any other ſolid objection to its doctrines being adopted, than the effect it would have upon old muſic, by ſoon rendering it unintelligible. At preſent the tenor cliff alone is thought an inſuperable difficulty in our country, by Dilettanti performers on the harpſichord; but if Salmon's ſimple and eaſy muſical alphabet were chiefly in uſe, the baſe cliff would likewiſe be ſoon rendered as obſolete and difficult as the tenor; ſo that two parts or cliffs out of three, in preſent uſe, would become unintelligible. The author's plan was ſimply this: inſtead of the eight or nine cliffs that were then in uſe, as,



to expreſs the whole ſcale of ſounds on the five lines and ſpaces in this ſimple manner:



G in every part of the ſcale being on the firſt line, *a* on the firſt ſpace, *b* on the ſecond line, &c. the letters preceding each ſeptenary implying baſe, mean, treble, ſupreme. To this propoſal there ſeems no cogent objection; profeſſors would not be humbled by having any thing to learn. The baſe clef, which every tyro knows, repeated in octaves, without changing a ſingle name or character, would accompliſh the whole buſineſs. The principal evil, and a great evil it would be, is the certainty of ſoon rendering all former muſic, printed or in manuſcript, obſolete and unintelligible. This has been effected in a great meaſure, lately, by new editions of the harpſichord and organ muſic of the laſt century, and the total rejection of every tenor clef in muſic for keyed-inſtruments; of which we have already pointed out the inconvenience. See ACCOMPANIMENT and CLEF.

COMPASS *of proportion*. See SECTOR and PROPORTION.

COMPASS *dials*, are ſmall dials, fitted in boxes, for the pocket, to ſhew the hour of the day by direction of the needle; which indicates how to place them right by turning the dial about, till the cock or ſtyle ſtand directly over the needle, and point to the northward; but theſe can never be very exact, becauſe of the variation of the needle itſelf. See DIAL.

COMPASS *Saw*. See SAW.

COMPASSES, or *pair of* COMPASSES, a mathematical inſtrument, uſed for the deſcribing of circles, meaſuring lines, &c. The common compaſſes conſiſt of two branches or legs, of iron, braſs, or other metal, pointed at bottom; and joined by a rivet, whereon they move, as on a centre. Thoſe are reckoned the beſt, part of whoſe joint is ſteel, and where the pin on which the joint turns is a ſteel ſcrew. The points ſhould alſo be made of hardened and poliſhed ſteel. In ſome the points are fixed; in others they may be taken off, and a drawing-pen, pencil, or dotting wheel, ſubſtituted in their room.

The invention of compaſſes is aſcribed to Talaus, nephew of Dædalus, by his ſiſter, whom, the poets ſay, Dædalus killed out of envy. We have compaſſes now of various kinds and contrivances, accommodated to the various uſes they are intended for; as,

COMPASSES *of three legs*, or *triangular compaſſes*. Their ſtructure is like that of the common compaſſes, ſetting aſide the exceſs of a leg, which has a motion every way: their uſe is to take three points at once, and ſo to form triangles: to lay down three poſitions of a map to be copied at once, &c. Two of the legs A, B (*Plate, Compaſſes, fig.* 1.) are jointed together like a common pair: the pin *a*, which connects them, has another leg D, jointed to it; the legs, A, B, are firſt ſet to two of the points, and the leg D is then moved farther from, or nearer to, the other legs by bending its joint; or it is turned round the pin *a* of the other legs as a centre, as occaſion may require.

Fig. 2, is another conſtruction of the triangular compaſſes. A, B, C, are three arms, at whoſe ends are jointed the arms *a*, *b*, *c*, carrying ſteel points; they are of ſuch lengths, that when cloſed they ſhall nearly meet in one point; by opening them as in the figure, they can be made to coincide with any three points within the reach of the arms.

COMPASSES, *Beam*, conſiſt of a long branch, or beam, carrying two braſs curſors; the one fixed at one end, the other ſliding along the beam, with a ſcrew to faſten it, on occaſion. To the curſors may be ſcrewed points of any kind; whether ſteel, pencils, or the like. To the fixed curſor is ſometimes applied an adjuſting or micrometer ſcrew, by which an extent is obtained to very great nicety. Mr. Ramſden conſtructed compaſſes of this kind whoſe micrometer ſcrew ſhews very perceptibly a motion of $\frac{1}{5000}$th part of an inch. It is uſed to draw large circles, to take great extents, &c. See *Plate, Compaſſes, fig.* 3, which exhibits a common pair of beam compaſſes. A A is a five-ſided bar, of mahogany, made very ſtraight and true; B, D are two frames of braſs, ſliding on the bar, that can be faſtened at any place by a clamp ſcrew *a b*, at the top of each; *c*, *f* are two pieces into which are inſerted the points, and are faſtened by a ſcrew; the ſliding frame B has a collar *g* ſcrewed to it, in which the ſcrew *h*, with a divided head, turns; this ſcrew is tapped into a piece of braſs faſtened at the end of the mahogany bar, ſo as to move the point at *f* very ſlowly when the ſcrew is turned.

COMPASSES, *Bow*, or *Bows*, are a ſmall ſort of compaſſes,

paſſes, that ſhut up in a hoop, which ſerves for a handle. Their uſe is to deſcribe arcs, or circumferences of circles of very ſmall radius. *Fig.* 4, is a ſmall pair of compaſſes, with a ſcrew for meaſuring ſmall diſtances very accurately, and deſcribing ſmall circles: *a* is one of the points faſtened to a ſocket, in which the ſcrew *b* works; *d* is a ſteel-bar attached to the ſame ſocket; *e* is a piece ſliding on the bar *d*, and carrying the other point; it has a projection above it, in which the ſcrew works; *f* and *g* are two pieces jointed to the points at one end, and to a ſmall handle *h*. at the other, which is uſed to hold them by. The head *l* of the ſcrew is divided into equal parts, which diviſions are read againſt a projecting part of the piece, holding the point *a*; and by turning it round one of the diviſions, the points are moved ſome fractional part of an inch, as $\frac{1}{100}$, or $\frac{1}{200}$, according to the number of threads in an inch of the ſcrew's length, and the number of diviſions on the head of the ſcrew.

Compasses, *Caliber*. See Caliber.

Compasses, *Clock-makers*, are very ſubſtantial, ſerving to cut paſteboard, braſs, &c. jointed like the common compaſſes with a quadrant, or bow, as the *ſpring compaſſes*, only its uſe is different; as ſerving here to keep the inſtrument firm at any opening. See Clock.

Compasses, *cylindrical and ſpherical*, uſed in taking the diameter, thickneſs, or caliber of round or cylindric bodies; ſuch as cannons, balls, pipes, &c. They conſiſt of four branches joined in a centre, two of them circular, and two flat, a little bent at the ends.

To uſe them, one of the flat points is put within the cannon, the other without: the two oppoſite points ſhew the thickneſs. See Caliber *Compaſſes*.

There are alſo *ſpherical compaſſes*, differing in nothing from the common ones, but that their legs are arched, ſerving to take the diameters of round bodies, &c. Another ſort of compaſſes has been lately invented, for meaſuring the diameter of round bodies, as balls, &c. which conſiſt of two flat pieces of metal, ſet at right angles, in a ſtraight bar or beam of the ſame; the one being fixed, and the other ſliding along it, ſo far as juſt to receive the round body between them; and then its diameter, or diſtance between the two pieces, is ſhewn by the diviſions marked on the beam.

Compasses, *Elliptic*. Their uſe is to draw ellipſes, or ovals of any kind: they conſiſt of a beam A B (*Plate, Compaſſes, fig.* 5.) about a foot long, bearing three curſors; to one of which may be ſcrewed points of any kind: to the bottom of the other two are rivetted two ſliding dove-tails, adjuſted in grooves made in the croſs branches of the beam. The dove-tails having a motion every way, by turning about the long branch, go backwards and forwards along the croſs: ſo that when the beam has gone half-way about, one of theſe will have moved the whole length of one of the branches; and when the beam has got quite round, the ſame dove-tail has got back the whole length of the branch. Underſtand the ſame of the other dove-tail.

Note, the diſtance between the two ſliding dove-tails is the diſtance between the two foci of the ellipſis; ſo that by changing that diſtance, the ellipſis will be rounder or ſlenderer. Under the ends of the branches of the croſs are placed four ſteel points to keep it faſt.

The uſe of this compaſs is eaſy; by turning round the long branch, the ink, pencil, or other point, will draw the ellipſis required. Its figure ſhews both its uſe and conſtruction.

Compasses, *German*, whoſe legs are a little bent outwards towards the top; ſo that, when ſhut, only the points meet.

Compasses, *Hair*, ſo contrived within ſide, as to take an extent to a hair's breadth. The outward appearance of the hair compaſſes is like that of a common pair of compaſſes; the peculiarity conſiſts in one of the legs A, being attached to the braſs by a ſpring B (*fig.* 6.), whoſe action throws the leg inwards, and is counteracted by a ſmall ſcrew D; by turning which the leg can be moved ſmall diſtances, and ſet to the greateſt nicety, without moving the joint.

Fig. 7, repreſents a pair of pocket compaſſes, the legs, *a*, *b*, of which are hollow, and contain, the one a pen, *d*, and the other a port-crayon *e*, at the oppoſite end of each point, *f* and *g*.

Compasses, *Lapidary's*, a piece of wood in form of the ſhaft of a plane, cleft a-top, as far as half its length; wherewith they meaſure the angles, &c. of the precious ſtones, as they cut them. In the cleft is a little braſs rule, faſtened there, at one end, by a pin; but ſo that it may be moved in the manner of the bevel; with this kind of ſquare they take the angles of the ſtones, laying them on the ſhaft as they cut them.

Compasses, *Proportional*, are thoſe whoſe joint lies between the points terminating each leg: they are either *ſimple* or *compound*. In the former ſort the centre is fixed, ſo that one pair of theſe ſerves only for one proportion.

Compasses, *Compound proportional*, conſiſt of two branches (ſee *fig.* 8), each pointed at either end with ſteel: the length of the branches is cut through, for a curſor to ſlide up and down; in the middle of which curſor is a ſcrew, ſerving to join the branches, and to fix them at any point required.

On the one leg are diviſions, ſerving to divide lines into any number of equal parts, for reducing of figures, &c. On the other are numbers, for inſcribing any regular polygon in a circle propoſed.

The uſe of the firſt is eaſy: Suppoſe v. gr. a right line required to be divided into three equal parts; puſh the curſor till the ſcrew be juſt on the figure 3; where fixing it, take the length of the given line between the two longeſt parts of the legs: the diſtance between the two ſhorteſt will be one third of the given line. In the ſame manner may the line be divided into any other number of parts.

For the uſe of the line of polygons: Suppoſe, v. gr. a pentagon required to be inſcribed in a circle: puſh the curſor till the middle of the ſcrew be againſt 5, the number of ſides in a pentagon; between the ſhorteſt parts of the legs take the ſemidiameter of the circle: the legs thus opened, the diſtance between the points of the longeſt parts will be the ſide of the pentagon to be inſcribed in the circle. And thus for a figure of any other number of ſides.

Fig. 9. is a pair of proportional compaſſes; the braſs part of the two legs A, B, have longitudinal openings in them, for the pin, round which they move as a centre, to ſlide in, and can be fixed at any place by a ſcrew *a*, ſo that the diſtance from the centre to the points *c*, *d*, ſhall be twice, three times, (or any other aliquot part) of the diſtance to the points *e*, *f*, and of courſe the openings at each end will be in the ſame proportion.

Fig. 10, repreſents a method of adapting a quick and ſlow motion to a pair of theſe compaſſes; *a* is a braſs bar, with an oblong opening cut in it, to receive a ſcrew, *b*, faſtened to one leg of the compaſſes; the other end of the bar, *a*, is cut into a ſcrew, with a fine thread, and has a nut, *f*, on it, turning in a collar jointed to the other leg of the compaſſes. When the ſcrew, *b*, is looſe, the compaſſes can be ſet to any opening; but when it is faſt, they can only be moved by turning the nut *f*. The ſcrew, *b*, is put into a hole in one of the legs of the compaſſes, ſo that it can eaſily be removed, and inſerted into a hole made in the moveable centre *g*, to give it a ſlow motion if required.

Compasses, *Proportional, with the ſector lines.* The ſtructure of theſe is ſo like that of the common proportional compaſſes, only a little nicer, that it needs no particular deſcription. See *fig.* 11.

The lines on the firſt face are the line of lines, marked *lines:* it is divided into 100 equal parts, every tenth numbered: and the line of chords, which goes to 60°, is marked *chords*.

On the other face are a line of ſines to 90°, and a line of tangents to 45°. On the other ſide are the tangents from 45° to 71° 34′; on the other, ſecants from 0° to 70° 30′.

For the uſe of theſe compaſſes: 1. To divide a line into any number of equal parts, leſs than 100: divide 100 by the number of parts required: ſlip the curſor till the line on the ſliding dove-tail be againſt the quotient on the line of lines; then the whole line being taken between the points of the compaſſes moſt remote from the centre, the aperture of the other will ſhew the diviſion required. 2. A right line given, ſuppoſed to be divided into 100 parts, to take any number of thoſe parts; ſlip the line on the ſliding dove-tail to the number of parts required; the whole line being taken between the points fartheſt from the centre, the aperture of the other two will include the number of diviſions required. 3. The radius being given, to find the chord of any arch under 60°; ſlip the line on the ſliding dove-tail to the degrees required on the line of chords; the radius being taken between the points fartheſt from the centre of the curſor, the aperture of the other line will be the chord required, provided the number of degrees be greater than 29; if it be leſs, the aperture taken from the radius will leave the chord required. 4. If the chord of an arch under 60° be given, and the radius required, ſlip the line on the dove-tail to the degrees given on the line of chords; the given chord being taken between the two points next the curſor, the aperture of the other will be the radius required. 5. The radius being given, to find the ſine of any number of degrees. Slip the line on the dove-tail to the degree on the line of ſines whoſe ſine is required; the radius taken between the points fartheſt from the curſor, the aperture of the other will give the ſine of the angle required. But if the ſine ſought be leſs than 30°, the difference of the apertures of the oppoſite points will be the ſine required. 6. The radius being given, to find the tangent of any number of degrees under 71°: if the tangent required be under 29° 30′, then ſlip the line on the dove-tail to the degree propoſed on the tangent line; the radius taken between the points fartheſt from the curſor, the aperture of the others will be the tangent of the degrees required: if the tangent required be above 29° 30′, but under 45°, the line on the curſor muſt be ſlipped to the degrees given on the tangent line; then the radius being taken between the points fartheſt from the curſor, the aperture of the others will be the tangent. If the tangent required be greater than 45°, but leſs than 56° 20′, ſlip the notch on the tangent ſide of the turned cheek to the degree 0 in the tangent line on the ſide of the compaſs; the radius taken between the points fartheſt from the curſor; the difference between the aperture of the other, and theſe, added together, will be the tangent required. Thus, for the tangents of other degrees under 71. After the like manner may the ſecant of any number of degrees under 71 be found.

Mr. Heath, a mathematical inſtrument-maker in London, conſtructed a pair of proportional compaſſes in 1746, with a curious and uſeful contrivance for preventing the ſhorter legs from changing their poſition, when theſe compaſſes were uſed. It conſiſted of a ſmall beam ſoldered to a ſcrew, and running parallel to the leg of the compaſſes, nearly of the length of the groove; in this beam a ſlit was made, which admitted of a ſliding nut, the other end of which fell into a hole in the bottom of the ſcrew, belonging to the great nut of the compaſſes. The ſcrew-pin of the beam paſſed through an adjuſter, by means of which the mark on the ſlider might be brought exactly to any diviſion. But the proportional compaſſes have been much out of uſe ſince the invention of the *ſector*, which ſee.

Compasses, *Spring*, or *Dividers*, are made of hardened ſteel, the head arched; which, by its ſpring, opens the compaſſes; the opening being directed by a circular ſcrew, faſtened to one leg, and let through the other, worked with a nut.

Compasses, *Triangular*. See Compasses *of three legs*, and Triangular.

Compasses, *Triſecting*, the invention of M. Tarragon, for the triſection of angles, geometrically.

The inſtrument conſiſts of two central rules, and an arch of a circle of 120 degrees, immoveable, with its radius; the radius is faſtened with one of the central rules, like the two legs of a ſector, that the central rule may be carried through all the points of the circumference of the arch. The radius and rule muſt be as thin as poſſible, and the rule faſtened to the radius hammered cold, to acquire an elaſticity; the breadth of the other central rule muſt be triple the breadth of the radius. In this rule there is a groove, with a dove-tail, to be faſtened on it, for its motion; in the centre of each rule muſt likewiſe be a hole. See the Journ. des Sçavans, Sept. 1688.

Compasses, *Turn-up*, a late contrivance to ſave the trouble of changing the points; the body is like the common compaſſes; towards the bottom of the legs, without ſide, are added two other points, beſide the uſual ones; the one carrying a drawing pen-point, the other a port-crayon; both adjuſted ſo as to turn round, and ſo be in the way of uſe, or out of it, as occaſion requires.

The points of ſmall compaſſes are tempered by a lamp and blow-pipe, heating them red-hot; when cold, they are hard: the larger are tempered by a charcoal fire and a blow-pipe, heating them to a cherry colour, then plunging them in water.

See M. Bion's Conſtruction and Uſes of Mathematical Inſtruments, by Stone; and Robertſon's Treatiſe on the ſame ſubject.

COMPASSEMENT *de feux*, in *Military Language*, a manner of fixing the diſtances between the chambers of mines, and diſpoſing of the ſauciſſons, ſo as to communicate the fire to them at one and the ſame inſtant of time.

COMPASSING, in *Naval Architecture*, a term uſed to denote ſuch pieces of timber as are incurvated into the figure of an arch.

Compassing *the king's death*, in *Law*. See Treason.

COMPASSION, in *Ethics*, a mixed paſſion, compounded of love and ſorrow, and excited by the ſight or recital of diſtreſs; or, as Dr. Hartley conciſely defines it, it is the uneaſineſs which a man feels at the miſery of another. Accordingly he traces it to ſeveral aſſociations, both in children and adults, upon which it ſeems to be grounded; and he obſerves, that perſons, whoſe nerves are eaſily irritable, and thoſe who have experienced great trials and afflictions, are in general, more diſpoſed to compaſſion than others; and that we are moſt apt to pity in thoſe diſeaſes and calamities which we either have felt already, or apprehend ourſelves in danger of feeling hereafter. A compaſſionate temper, ſays this writer, being great matter of praiſe to thoſe who are endued with it, and the actions which flow from it being a duty incumbent on all, men are led to practiſe theſe actions, and to inculcate upon themſelves the motives of compaſſion, by attending to diſtreſs, actually preſent, or deſcribed in hiſtory, real or fictitious.

Hobbes makes this a merely ſelfiſh paſſion, and defines it, as being fear for ourſelves; Hutcheſon reſolves it into INSTINCT; but Dr. Butler much more properly conſiders compaſſion as an original, diſtinct, particular affection in human nature.

According to Dr. Cogan, in his "Treatiſe on the Paſſions," compaſſion is that ſpecies of affection, which is excited either by the actual diſtreſs of its object, or by ſome impending calamity which appears inevitable. It is, ſays this writer, a benevolent ſorrow at their ſuffering or approaching miſery. The etymology of the word expreſſes this idea with ſtrict propriety, as it ſignifies "ſuffering with the object." Compaſſion is always connected with a diſpoſition to relieve, and will always prompt to vigorous exertion, wherever there is a poſſibility of ſucceſs; unleſs ſome important conſiderations ſhould render the endeavour improper or unjuſt. It has no neceſſary connection with the character of its objects; their diſtreſs being a ſufficient excitement. From the great extent and univerſality of this affection, it may be juſtly conſidered as a generic name, comprehending ſeveral other affections which have a more ſpecific application, as *mercy*, *commiſeration*, *pity*, &c. Dr. Reid remarks, that it ſeems to be falſe religion alone that is able to check the tear of compaſſion. We are told, he ſays, that in Portugal and Spain, a man condemned to be burned as an obſtinate heretic, meets with no compaſſion, even from the multitude; obſerving, that they are taught to look upon him as the enemy of God, and doomed to hell fire. But ſhould not this very circumſtance, he adds, move compaſſion? Surely it would, if they were not taught that, in this caſe, it is a crime to ſhew compaſſion, or even to feel it. Hobbes of Human Nature, cap. ix. ſect. 10. Hutcheſon's Enquiry into Moral Good and Evil. Butler's Sermons, ſerm. v. and vi. Hartley's Obſervations on Man. Cogan on the Paſſions. Reid's Eſſays on the Active Powers of Man, ch. iv.

COMPATIBLE, ſomething that may ſuit, or conſiſt with another. See INCOMPATIBLE.

COMPENDIUM, an abſtract, epitome, or reduction of a large matter into a little compaſs. See ABSTRACT and EPITOME.

COMPENSATION, an action whereby any thing is admitted as an equivalent to another.

COMPENSATION, in the *Civil Law*, is a kind of right, whereby a debtor purſued by his creditor, for the payment of a debt, demands that the debt may be *compenſated* with what is owing him by the creditor. *Compenſation* is equivalent to payment, and anſwers to that which is called SET-*off*, in common law.

COMPENSATION-*Balance*, in *Horology*, is the balance of a chronometer, ſo ingeniouſly contrived, that two oppoſite actions counteract each other's natural effects at all times upon it, and equaliſe its momentum under all the changes of temperature experienced in different climates and ſeaſons. The oppoſition of two natural effects, produced by an artificial arrangement of the acting parts, is very properly called the *compenſation*, which has been effected in various ways. The moſt ſimple compenſation that has been produced in a machine for meaſuring time, is that which depends upon the variable fluidity of the oil applied to the pivot holes of the balance arbor, and of the other arbors of a watch; oil, it is well known, however good, is more fluid in hot weather than in cold, and therefore diminiſhes the friction at the pivots more in ſummer than in winter, the conſequence of which variation in the friction of a watch with the ordinary crown-wheel eſcapement, would have its rate accelerated in the former ſeaſon, and retarded in the latter, by this ſimple cauſe, if there were no compenſating property in the ſtructure of ſome part of the mechaniſm; this property naturally exiſts in the balance and balance-ſpring, both which are ſubject to have their dimenſions enlarged by heat, and contracted by cold; and theſe changes alternately occaſion retardations and accelerations in the rate of going; but in ſuch a way, that when the watch is diſpoſed to have its rate accelerated by the moſt fluid ſtate of the oil, it is alſo diſpoſed to have the ſame retarded by the contemporary enlargement of the balance and balance-ſpring; hence the quantity that one of theſe diſpoſitions prevails over the other in any watch, when regulated to mean time at a mean temperature, conſtitutes its liability to vary its rate of going in different months of the year. Berthoud, who attempted to proportion the thickneſs of his pivots to ſuit the oil with a given balance, ſo as to produce an approximation towards a good compenſation, has called this the *natural* compenſation, which is a very proper appellation, as it exiſts in a certain degree in all chronometers and watches that have oil applied to them. This natural compenſation, however, is found to be a very imperfect one, and unfortunately interferes with the effects produced by the better compenſations, which, in oppoſition to this, may be called the *artificial* compenſations. To baniſh the interference of the variable effects produced by oil, is one of the difficulties, and indeed now the principal one, that oppoſes the efforts of the chronometer-maker, to make the action of his mechaniſm permanently uniform.

The mechaniſm of the artificial compenſations may be arranged under three diviſions, *viz.* 1ſt, That which applies excluſively to the balance-ſpring; 2dly, That which applies excluſively to the balance itſelf; and, 3dly, That which applies partly to the ſpring and partly to the balance: for the ſake of order, we propoſe to deſcribe the different compenſation-balances agreeably to theſe diviſions, which are alſo nearly agreeable to the order of time in which they were invented.

Compenſations at the Spring.

1. *Harriſon's Compenſation Curb.*—We have ſaid, under our article CHRONOMETER, that Mr. James Harriſon of Barton, in Lincolnſhire, was the firſt perſon who applied a ſelf-compenſating piece of mechaniſm to the balance of a watch, which contrivance, according to his provincial dialect, he called a *kirb*, and which we have taken the liberty to name a *curb*. *Fig.* 1. of *Plate* XXVIII. of *Horology*, repreſents the balance, balance-ſpring, ſmall cocks, and curb, as they would be ſeen by an eye placed directly over the back of the pillar-plate, when the large cock is taken off, that bears the verge-pivot: AA is the plate on which the mechaniſm is placed; B the balance of one uniform metal; C the ſpiral ſpring of regulation; DE the thermometrical curb, ſo contrived as to lengthen the effective length of the ſpring in the different degrees of temperature, without manual adjuſtment; Gg a double cock to which the curb D E is attached; and F the ſmall cock, or ſtud, to which the exterior end of the ſpring is pinned. The thermometrical curb, D E, is compoſed of two long ſlender ſlips, one of braſs and the other of ſteel,

pinned together in different places, and is attached to the ſmaller half *g* of the double cock G *g*, ſo that it may be brought nearer to G, or removed farther from it at pleaſure, before *g* is fixed to G, in order to place it at the requiſite point between *a* and *b* of the ſpiral; the double cock is repreſented in the figure as though it were fixed faſt by a ſcrew and ſteady pin to the plate; but in the original time-keepers, it was adjuſtable between two parallel pieces, that allowed it to approach the ſtud F, or recede from it, for the purpoſe of aſcertaining particularly the beſt length of the curb, for effecting the requiſite compenſation: the ſide of the curb next to D was ſteel, and the ſide next to E braſs, and the effect produced by changes of temperature was thus: when the time-keeper was expoſed to heat, the balance, and balance ſpring, had their dimenſions enlarged, ſo that the momentum of the balance was increaſed, ſuppoſing its arc of vibration unaltered, and the force of the ſpring was diminiſhed, or at leaſt would have been by its elongation, if the curb had not been applied; and the natural conſequence would have been for the piece to retard; but the ſame heat, which naturally produces theſe changes in the balance and balance-ſpring, produces ſuch a change in the ſhape of the curb, as counteracts theſe natural effects; in the caſe of heat, the braſs part, E, of the curb becomes more lengthened than the ſteel part D, by reaſon of its ſuperior expanſibility; the conſequence is, that the compound piece, D E, becomes convex on the braſs ſide E, and concave on the ſteel ſide D; that is, the remote or free end of the curb, conſidered as an index, moves from *a* towards *b*, and as this end carries two pins between which the ſtraight end of the ſpring paſſes, theſe pins, and not the ſtud, form the limit of length at all times of the regulating ſpring, which conſequently is curbed as to its effective length, under all the variety of elongations, that it experiences from different degrees of heat; ſo that it may be ſaid to be always both lengthening and ſhortening in nearly the ſame proportion: on the contrary, when the piece is expoſed to cold, or to ſpeak more ſcientifically, is expoſed to a low temperature, the ſteel ſide, D, becomes convex, and the braſs ſide, E, concave from its greater contraction, and the free end of the curb moves from *b* towards *a*, thereby mechanically lengthening the ſpring, as it naturally contracts, in a degree ſufficient to check the velocity which the balance would acquire from its diminiſhed dimenſions. Thus, whether it is ſummer or winter, in hot or in cold climates, the compenſation-curb is calculated to counterbalance the natural effects of changes of temperature on the dimenſions of the balance and of its regulating ſpring.

It has been aſſerted, that the *elaſticity* of the balance-ſpring is affected by changes of temperature; but we conceive it to be its *force*, or that power which depends on its *length* that is naturally altered, and not, at leaſt in any ſenſible degree, that property which depends upon its *temper*. This contrivance, we have ſaid, in another place, laid the foundation of modern chronometry, though it was afterwards found to be a better application of the compound bar, that the balance itſelf ſhould bear it, in order that the dimenſions of the balance and of the compenſation pieces might be affected in a contemporary manner by the variation of atmoſpheric temperature, ſo that the artificial changes going on in the balance itſelf might compenſate the changes naturally produced in it and in the ſpring, inſtead of the artificial changes in the ſpring being made to compenſate the natural changes in its dimenſions, and in thoſe of the balance. We have before ſaid, that this mechaniſm was invented and uſed ſo long ago as the year 1726, and that it is incapable of the uſual adjuſtment for rate, except at the fixed ſtud, from which the faſtening pin muſt neceſſarily be taken, to admit of the ſpring's being lengthened or ſhortened.

Compenſation by F. Berthoud.

In the year 1760, which was about ſeven years before the Board of Longitude publiſhed the principles of Harriſon's Time-keeper, Mr. F. Berthoud, the famous clock and watch-maker of Paris, contrived and introduced, into No. 1, of his marine clocks, a compenſation-curb, acting on the ſpiral ſpring of the balance in a manner ſimilar to the action of Harriſon's curb, except that the backward and forward motion of his *pince-ſpiral*, or curb, was produced by the difference of two direct expanſions agreeably to the diſpoſition of the grid-iron pendulum, which Harriſon had previouſly invented, (for the deſcription of which ſee the ſection, "Aſtronomical clock, by Mr. Reid of Edinburgh," under the article CLOCK.) The mechaniſm by Berthoud, is repreſented in *fig.* 2. of *Plate* XXVIII., the eye being, as before ſuppoſed, to be directly over the pillar plate of the frame; the circle A A denotes the plate juſt mentioned; B B, the grid-iron frame, attached to the ſaid plate, and compoſed of alternate bars of ſteel and braſs, joined together by end-pieces like the compenſation-pendulum alluded to, which therefore need not be again minutely deſcribed; the pair of braſs bars in the middle of the frame, or grid-iron, are thoſe which act by protruding more or leſs in different degrees of heat againſt the tail-piece D, of the double lever D E, moveable on an arbor with pivots borne by the plate and cock G, or by G made as a double cock; H is the principal cock, in which the balance pivot runs in the triangular hole, made by three friction-rollers, not ſhewn in the figure; the *pince-ſpiral b*, and arm *a* are faſt to an arbor which is pivoted into the cock H, and a ſmall cock under it, which is attached to it; this arbor is parallel to the balance verge, and is ſo contiguous to it, as to be in one of the eccentric points, from which the ſpiral of the ſpring which it holds is geometrically deſcribed; that is, at half the diſtance from the verge, that the two neareſt ſpirals are from each other; on each of theſe two levers, *a* and *b*, is a ſliding piece of metal; that on *a* for the lever E to reſt againſt, and that on *b* to have a ſlit for receiving the thread of the ſpiral ſpring; they are both fixed by preſſing ſcrews to their reſpective levers, when adjuſted to their proper places thereon; but *b* is prolonged to *d*, which is attached to the graduated L piece by the ſcrew *e*, and this L piece has a pointer, uſed as an index for the graduations on the bridge I, that lies acroſs the grid-iron frame, when attached to the plate A A. K is a ſpring, preſſing againſt a tail-piece of the lever *a* to keep it always in contact with the lever E; C is the ſpiral regulating ſpring, as in an ordinary watch, and F an adjuſtable ſtud, for the exterior end of the ſpring, with an oblong perforation for the preſſing ſcrew; the interior end of the ſpring being faſt to a collet on the verge, which is adjuſtable by friction. The mechanical action is thus produced; the difference of the expanſibilities of the ſteel and braſs rods of the grid-iron frame becomes ſenſible at the pin D, in the tail-piece of the bent lever D E, moveable in a point of bridge G, between thoſe two letters; the part E, being longer from the centre of motion than the part D, which is acted on, moves faſter and carries before it the lever *a*, and together with it the *pince-ſpiral b*, and L piece with the ſcrew *e*; and it is obvious, that, as the ſliding piece, borne by lever *a*, limits its effective length from its place of contact with lever F, the relative lengths of theſe two levers may be varied at pleaſure by adjuſtment, till the effect produced on the ſpring by the grid-iron frame, through the medium of theſe levers, is according to its due quantity; and the pince-ſpiral will go and come in a manner ſimilar to the motion of Harriſon's curb, though the law of their motion is different, one depending on direct expanſion, and the other on lateral curvature. The graduations of the L piece are for bringing the machine to time, the end, *d*, being the index, and the ſcrew, *e*, the inſtrument of adjuſtment; and the index of the L piece ſhows, on the graduated cock I, the ſituation of the pince-ſpiral under all the variations of temperature. Beſides No. 1, Nos. 3, and 8 of the marine-pieces of this author had the compenſation we have here deſcribed, which, though complex, would no doubt anſwer its purpoſe as well as Harriſon's more ſimple contrivance; and though the idea did not originate with the contriver, yet it will be acknowledged, that there is evident ingenuity in the arrangement and adaptation of the acting parts of the mechaniſm; the effect alſo produced by the mechaniſm before us muſt be regular and permanent, when the materials are good, and the work well executed. (See "Traité des Horloges Marines" par F. Berthoud. Paris 1773.)

Harriſon's Compenſation improved by F. Berthoud.

After the Board of Longitude had publiſhed the principles of Mr. Harriſon's Time-keeper, Mr. F. Berthoud perceived that Harriſon's compenſation-balance might be improved by introducing the action of a lever, capable of adjuſtment for any given quantity of effect, without moving the cock that holds the compenſation bar; the conſtruction he adopted was thus; A, in *fig.* 3; of the plate already named, is the cock for the balance pivot, ("Hiſtoire de la Meſure du Temps") which balance is not neceſſary to be ſhewn, B is the curb lever, detached from the compenſation bar, and turning on a ſhort arbor pivoted into the cock A, and an under cock borne by this not ſeen, the centre of its motion being at one ſide of the balance verge, as in Berthoud's former balance; the ſpring under the cock, that urges it towards the ſcrew of C, is concealed from ſight; C is the compound or compenſation bar, fixed in the chops of a faſt bridge D, and having, at its free end, a ſcrew with its point bearing on the tail-piece H of the curb-lever B, which curb-lever has a ſliding piece with a narrow groove to admit the thread of the ſpring, and is fixed by a preſſing ſcrew in any given ſituation; E is what the French call a *piton*, or adjuſtable frame of the ſtud, ſtanding on four ſcrews, as feet, which allow it to be brought into the plane of the ſpiral-ſpring, ſo as not to force it from its natural poſition; the ſtud F, that holds the exterior end of the ſpring ſlides in the *piton*, when under adjuſtment for diſtance, and is then fixed by a preſſing ſcrew, paſſing through the contiguous end of the ſpring G, which turns on a ſtud or ſcrew, at its remote end when looſe. The manner in which this mechaniſm acts will be readily apprehended from what we have ſaid of Harriſon's, and the preceding compenſation curb, of which it conſtitutes an union, thus: when the temperature is high, the compound bar, C, is affected exactly in the way we have juſt deſcribed Harriſon's to be affected, and the chops of the bridge, D, allow the lengths of the curb lever B, and of its tail-piece, preſſed by the ſcrew, to be adjuſted according to any given ratio as they reſpect each other; and as the quantity of effect to be produced on the ſpiral ſpring depends upon this ratio, with a given compound bar balance, eſcapement, and maintaining power, it is obvious that the adjuſtment for temperature may be brought to the requiſite degree of exactneſs by a few ſucceſſive trials in the oppoſite extremes of temperature.

The Application of Harriſon's Curb to a common Watch.

After Berthoud had made the alterations, which we have juſt deſcribed, in Harriſon's curb, he turned his mind towards ſimplifying it ſo as to become uſeful in a common watch; the manner in which he ſucceeded in doing this is ſhewn in *fig.* 4 of our preſent plate, where it will appear by inſpection how the action takes place, particularly as we have placed the ſame letters of reference to the ſame parts, as in *fig.* 3; the difference of the two contrivances conſiſts chiefly in the ſtud, F, being here fixed faſt to the circular plate of the frame; in the curb-lever being bent and having its centre of motion on a ſeparate ſmall bridge, H; and in the oppoſing ſpring, K, being attached to the face of the plate itſelf; otherwiſe the adjuſtment for temperature is performed as in *fig.* 3, and is equally capable of taking in the extreme limits of temperature. (For another diſpoſition ſomewhat ſimilar to the preſent one, ſee Berthoud's "Supplement au Traité des Horloges Marines." *Plate* III. *fig.* 8.)

Compenſation by Mr. Alexander Cumming.

Mr. Cumming publiſhed his book on "The Elements of Clock and Watch-work," in the year 1766, in which he has given an ingenious though complex method of compenſating the effects of heat and cold on the balance and balance-ſpring, different from the foregoing ones, and depending on the difference of the direct expanſions of two ſeparate and different metals, aided, like Berthoud's, by the introduction of adjuſtable levers; whether the invention preceded or followed Berthoud's grid-iron frame and lever, is a conſideration which does not, perhaps, affect either of their two claims to originality, as Harriſon's curb was moſt probably heard of, if not previouſly known, by both the mechaniſts in queſtion; nor does it appear that either of the two complex methods here ſpoken of has been copied by others in practice. *Fig.* 1. of *Plate* XXX. of *Horology*, repreſents a view of Cumming's mechaniſm of compenſation, without the balance, as viewed by the eye placed directly above it, when fixed to the back of the pillar-plate of the frame. The outermoſt circular rim, AAA, is of ſteel, and has eleven ſmall rollers revolving on as many pins or ſtuds inſerted into the plane of the rim, and the interior rim, BBB, which reſts againſt the rollers, is of braſs, but is not an entire circle: one end of this interior, or braſs rim, is ſcrewed faſt to the plane of the ſteel rim, by means of its enlarged extremity being made to lie upon the plane of the ſteel rim, as ſhewn in the figure; in this ſituation it is clear that the exceſs of the braſs rim's expanſibility will make its oppoſite ends approach each other in a high temperature, and recede in a low one, while the friction-rollers will prevent jerks; hence any object oppoſed to the free end of the braſs rim will be puſhed forwards by it, as the temperature is raiſed, which effect affords the means of alternately lengthening and ſhortening the ſpiral ſpring of the balance in the following manner; the free end of the braſs rim preſſes againſt the end, *a*, of a lever moveable on a ſtud about the middle of it, and the oblong ſlit made in the oppoſite end of the ſame lever receives a pin inſerted into the contiguous end of a ſecond lever *b*, moveable about its remote end round a ſocket concentric with the balance-verge, or nearly ſo; the lever, *b*, which may be called the curb-lever, has two pins in underneath, not ſeen in the drawing, between which the outermoſt thread of the ſpiral ſpring paſſes; hence it is plain, from an inſpection of the figure, that when the end, *a*, of the ſlit lever is puſhed outwards, its oppoſite end draws inwards the pin of the curb-lever, and with it the curb, ſo as to ſhorten the effective length of the ſpring in this caſe; and on the contrary, when the braſs rim ſhortens by a low temperature, the contrary effect takes place: for the end, *a*, of the ſlit lever follows the free end of the ſaid rim as it retires in contracting, in conſequence of a ſpring, not ſeen, impelling it into contact with this end at all times; the ratio of the two acting ends of the two levers from their reſpective centres of motion is adjuſted by the horizontal arbor, *d*, ſquared at the end to receive a key; for as the interior end of this arbor is formed into a ſcrew that paſſes into a tapped hole in a ſquare nut on which is the centre of motion of the ſlit lever; the ſaid ſquare nut is made to ſlide in an oblong hole of the plate below the lever; and thus the different parts of the ſlit may be made, ſucceſſively, to impel the pin of the curb-lever, as the compenſation may be found on trial to require. The balance, of courſe, is placed above this mechaniſm, and vibrates free from it. We obſerve that in the original drawing given by Cumming, (*fig.* 5 of his *Plate* XIV.) the ſpiral is made to turn the wrong way about, ſo that the effect of heat will be to elongate the ſpring, which conſtruction would double the natural effect of variations of temperature inſtead of compenſating them, as the contrivance is intended to do, and would do, if rightly conſtructed; but we ſee no reaſon to doubt this being as effectual and permanent as any of the foregoing modes of producing a compenſation, when the ſpiral is bent the right way round, as we have placed it.

Berthoud's Compenſation by a Braſs Arch.

Another method of producing a compenſation, different from any of the preceding ones, in its mode of application, comes next under our conſideration, as another production of the French clock and watch maker, whoſe name we have had frequent occaſion to mention with reſpect.

Fig. 5. of *Plate* XXVIII. exhibits the plan of all the eſſential parts of this contrivance, in an intelligible manner; A, as uſual, is the principal cock over the pillar plate; B, the balance of one metal; C, the ſpiral ſpring; D, an arch of braſs with its ends reſting in two ſloping notches filed into the ſteel bar, E, which is fixed by a ſcrew, near E, in the middle, to the plate, ſo that it may be at liberty to yield both ways to the action of increaſed or diminiſhed temperature on its total length; F is, as before, the ſtud to hold the exterior end of the ſpring, while the interior one is faſt to a collet on the balance-verge; G*g*, is a bent lever, with a pin in its ſhort end, *g*, and its long end pointed as an index, to reach to the diviſions, H, made on the plane of the plate, which bears the mechaniſm; the effect is thus produced; the braſs arch, D, is more elongated than the ſtraight ſteel bar, E, with the ſame increaſe of heat; this arch carries a ſmall ſcrew, the head of which is juſt oppoſite the pin, *g*, already mentioned, between which ſcrew and pin the outermoſt coil of the ſpiral ſpring paſſes; now if the ſcrew and pin were made to approach, till they both ſhould touch the ſpring at oppoſite ſides, they would become in place of a curb, and there limit the length of the ſpring that comes into action; on the contrary, if they were made to recede from each other, till the ſpring acted up to the ſtud, F, placed on the plate, they would be ſuperfluous; but when they are placed at ſuch an intermediate diſtance from each other that the ſcrew limits the opening of the ſpiral, and the pin its cloſing, before the part of the ſpring near the ſtud is moved by the motion of the balance, then the natural effective length of the ſpring is controlled, and the pin and ſcrew together become a ſpecies of curb, that limits the effective length of the ſpring from an undiſtinguiſhed point, lying ſomewhere between the ſtud and the ſaid pin and ſcrew; which indiſcriminate point will always be nearer to the ſtud the more the pin and ſcrew are removed from each other, and *vice verſâ*; hence it is eaſy to ſee; that moving the index, G, forwards or backwards, on the graduated portion of a circle, H, will bring the pin, *g*, nearer to, or remove it farther from, the ſcrew head, than a mean diſtance, and will thence affect the rate depending on the effective length of the ſpiral ſpring, with a given balance, maintaining power, and eſcapement; but it is the ſame thing if the index be ſuffered to remain, and the ſcrew be brought nearer to the pin; for the one limits the right hand and the other the left hand excurſion of the balance; this is the preciſe operation of the contrivance; the ſuperior elongation of the braſs arch over the ſteel bar ſhortens the radius of curvature of the arch, and makes the ſcrew-head approach the ſpring, more or leſs, agreeably to the change of temperature, to which the acting parts are expoſed. The law by which the approach is effected is ſomewhat different, however, from that by which an expanſion-rim is guided, with one of its ends at liberty; and the manner alſo in which the effective length of the ſpring is limited, allows a long ſcale of lengths, in a correſponding ſhort ſcale of diſtances between the ſcrew head and pin; the latter of which laws is evidently diſadvantageous to the nicety of the adjuſtment for temperature; beſides, when the braſs arch and the ſteel bar are found on trial not to be in their due proportions to each other, the remedy cannot be applied without varying the original proportions, by lengthening or ſhortening the verſed ſine, as the caſe may be, which alteration will require the mechaniſm to be diſplaced.

Improvement on the laſt Compenſation.

Berthoud, having diſcovered the inconvenience and objections to the laſt deſcribed compenſation curb, propoſes another in his "Hiſtoire du Temps," tom. ii. p. 101 and 102, thus: A, *fig.* 6, *Plate* XXVIII, is the principal cock, mounted as uſual on the pillar plate behind; B is again the balance of one metal; C, the uſual ſpiral ſpring; D *d b*, a rack moveable on a ſocket concentric with the balance verge, with ſome additional apparatus carried by it; E is a ſecond cock; and F a third, bearing the *piton*, or ſliding ſtud, with its frame and ſecuring ſpring as in *fig.* 3 of the ſame plate already deſcribed; G is a pinion with an arbor ſquared at the projecting end, to receive a key, which pinion has its teeth formed ſuitable to impel the teeth of the rack D *d*; *a* and *b* are two compound bars of braſs and ſteel, ſoldered together with hard ſolder, inſerted at *d* into a bearing piece, and kept faſt by a preſſing ſcrew *e*, urging them together with the looſe piece, *d*, interpoſed, and kept parallel by a clamping piece *c*; the rack has a circular perforated groove, which allows it to paſs backward and forward by the action of the pinion, while the heads of the two ſcrews, *f* and *g*, confine it to the ſame plane on the back of the plate; and, laſtly, the compound bars, *a* and *b*, have each a pin at their free extremities, which contain between them the laſt coil of the ſpiral ſpring, the action of which is limited preciſely in the manner deſcribed in our laſt compenſation mechaniſm; here, however, the law of flexure is again the ſame as in Harriſon's, though the law of limitation in the effective length of the ſpring is different: the latter, as we have ſeen, depends on the quantum of play between the pins, whereas, in the former, there was no play at all, and the curb itſelf was the limit; ſeeing the effective length of the ſpring diminiſhes as the pins approach each other, the exterior laminæ of the compound bars, *a* and *b*, muſt neceſſarily be braſs, and the interior ones ſteel, to ſhorten the ſpring in high temperatures, and the contrary; when the effect produced is too great, the clamping piece, *c*, is carried outwards towards the pins, in order to ſhorten the bars, which have their lengths meaſured from this clamp; but when the effect produced is too little, the ſaid clamp muſt be brought inwards towards *d*, to lengthen the bars ; ſo that the ſcale of adjuſtments here runs along the length of the two parallel compound bars, as it relates to the variations of temperature ; while the adjuſtment for a mean rate is made by the index *b*, which ſhews the quantum on the contiguous portion of a divided circle. Still, we think, that while a ſmall variation in the play, between the curbing pins, produces a great variation in the effective length of the ſpring ; this contrivance can have no pretenſions to rank in utility with ſome of the more recent inventions, that place the compenſating parts on the balance itſelf.

Compenſation by Breguet.

A compenſation ſimilar in effect to the two foregoing ones by Berthoud, but more ſimple than the latter, is that which Breguet of Paris has applied with ſucceſs to his common watches ; this compenſation is ſhewn in *fig.* 7 of *Plate* XXVIII. where the bounding circle denotes the back plate of the frame ; A the principal cock ; B the balance of one metal ; C the common ſpiral ſpring ; D *d c* a three armed piece, called by the French a *rateau*, to which is attached the mechaniſm of compenſation thus : the curvilinear fork, *a b*, is compoſed of two metals : each prong conſiſting of a ſlip of ſteel and a ſlip of braſs, ſo attached together, that the ſteel is the exterior, and the braſs the interior part in each ; the end *a* is ſcrewed to the lever D, and the end *b* is looſe, conſequently at liberty to approach or recede from the ſpiral ſpring, as the changes of temperature affect the fork ; the interior end, *a*, of the fork bears a pin near the letter *b*, not ſeen by reaſon of the lever D, which lies over it, and a ſecond pin ſimilar to the other is carried by the lever D, between the two largeſt coils of the ſpiral : theſe two pins limit the effective length of the ſpring exactly in the way that the two preceding compenſating contrivances have been explained to do, for which reaſon we do not repeat what we have already ſaid on this part of the ſubject ; the alternate inward and outward motions of the pin, *b*, regulate the diſtance between the two pins, on which the play depends, and conſequently the length of the ſpring alſo, as it has regard to the action ; the prong *a* has a tendency to become ſtraight by heat, in conſequence of the concave part being braſs, but the prong, *b*, has a tendency to become ſtill more convex in conſequence of the braſs being the convex part ; the joint effect of which alterations of ſhape and poſition will be, that, as the balance and its ſpring become enlarged, the ſpace between the curbing pins will become diminiſhed, and the contrary. The watch is regulated for mean time by the index part *d* of the three-armed *rateau*, and the third arm, *c*, contains a pin about the middle of the ſpiral ſpring, which we conceive to be the banking pin, though no mention is made of it in the original deſcription. " Hiſtoire de la Meſure du Temps, by Berthoud."

Compenſation by Mr. James Scott.

In May of the year 1805, Mr. James Scott, of Grafton Street, Dublin, publiſhed an account in Mr. Nicholſon's Journal, (vol. XI. p. 19—21., 8vo. ſeries) of a compenſation curb which acts in a manner ſomewhat analogous to that which we have deſcribed as the invention of Cumming ; but it is evident he had not previouſly ſeen the one alluded to, nor yet Berthoud's, otherwiſe he would not have ſaid in his letter to Mr. Nicholſon, that " artiſts have not been able to invent a compenſation-curb adjuſtable to the exact expanſion required." The contrivance now before us is ingenious, and we preſume might be applied to an ordinary watch with conſiderable advantage ; though we cannot perſuade ourſelves that any method of curbing the regulating ſpring, after it has been adjuſted for iſochroniſm, affords ſo good a compenſation, as the mechaniſm of compenſation now uſually applied to the balance itſelf. *Fig.* 2. of *Plate* XXX of *Horology*, ſhews all the parts of Mr. Scott's compenſation-curb, as given by himſelf in the original account ; but as his deſcription did not ſeem very intelligible to us at the firſt reading, we hope to be excuſed the liberty we take of giving our own account of the contrivance : A A is an index of ſteel, with a circular part embracing a dove-tailed groove that ſurrounds the balance verge in the upper plate of the frame ; to this ſteel index is attached, by a ſcrew and ſteady pin, one end of a compound circular bar, B B, ſo formed, that the ſteel part is the exterior, and the braſs part the interior ; to this compound bar is faſtened a ſecond compound bar C C, alſo circular, by means of a clamping piece and ſcrew at D ; a looſe piece of metal, interpoſed between the two circular bars, being preſſed by the ſcrew, the outer one keeps the inner one cloſe to the ſhoulder of the clamping piece, which cannot be ſeen in the figure ; but it is eaſy to conceive that ſuch a clamping piece will apply at any part of the circular bars ; the bar, C C, has the braſs part exterior, and the ſteel part interior ; E is the ſtud in the plate, that holds the outward end of the ſpiral regulating ſpring, intended to be curbed ; and the interior compound bar, C C, paſſes between two ſteady pins, inſerted in the plate at *a*, a ſhort diſtance from *b*, where the curbing pins are fixed, that embrace the laſt coil of the ſpring : whenever the index, A A, is moved, in regulating for mean time, it carries with it the two concentric compound bars, and the curbing pins ſlide along the coil of the ſpring, ſo as to lengthen or ſhorten it as the caſe may be ; ſuppoſe, now, that the regulation for rate be made, and that the balance has its temperature elevated, the tendency of the outer circular bar will be to open, or enlarge its radius of curvature, which action will bring the interior compound bar and its curbing pins nearer to the index, and ſhorten the balance ſpring a little ; but this action is not ſufficient to produce the whole requiſite effect ; the tendency of the interior circular bar C C, on the contrary, is to cloſe, that is, to approach the index, in conſequence of its radius of curvature becoming ſhorter, while its end at D is clamped to the free end of B B ; and it is the amount of theſe two contemporary motions, produced in the interior compound bar, C C, that conſtitutes the motion of the curbing pins at *b*, along the ſpiral ſpring, in a direction towards the index A A. In a low temperature, juſt the reverſe takes place ; the outer compound bar, B B, has its radius of curvature ſhortened, and the inner one, C C, has its radius of curvature, on the contrary, lengthened in this caſe, ſo that the joint effect is to make the curbing pins retire from the index to lengthen the regulating ſpring ; which alternate lengthening and ſhortening of the balance-ſpring's effective length in heat and cold, form the compenſation for the correſponding variations in the momentum of the balance and force of the ſpring. The excellence of the preſent contrivance conſiſts in its affording a ſcale of adjuſtments ; for moving the clamping piece, D, forwards, towards the middle of the concentric circular bars of compenſation, leſſens the effect, and removing them back, towards the open ends, increaſes the effect to be produced on the balance-ſpring, by giving a greater or ſmaller range of motion to the curbing pins. The inventor's rule for the thickneſs of the compound bars is, that each lamina be of the thickneſs of an ordinary main ſpring of a common watch, ſo that the compound pieces may be each of twice the ſaid thickneſs.

COMPENSATIONS *on the Balance.—Thermometer of Peter le Roy.*

We have ſaid under our article CHRONOMETER, that Harriſon was the firſt perſon who ſuggeſted the idea of the balance carrying its own compenſation, and Peter le Roy was the firſt who in 1766 ſucceeded in ſuch a conſtruction; in our notice of this invention, however, there is a typographical omiſſion which we beg leave to correct here before we proceed to our deſcription; it is ſaid under the article juſt referred to, that the compenſation was effected "by means of two thermometers, one of mercury and the other of alcohol, attached to, and carried by, the balance itſelf;" inſtead of "one end of each bearing mercury, and the other end alcohol, &c." as will now be more clearly underſtood. *Figs.* 1 and 2 of *Plate* XIX. of *Horology*, exhibit ſo much of the balance of Peter le Roy as is neceſſary for explaining its conſtruction; A A, in *fig.* 1, is a portion of the arbor or verge to which the balance B is attached by ſcrews; C is a ſmall ring attached to the inferior part of the verge which holds the two ſcrews of regulation for mean time, and which alſo clamps the horizontal parts of the two glaſs thermometrical bent tubes, D and E, placed diametrically oppoſite to each other, one of which is ſeen in a detached ſtate in *fig.* 2; theſe tubes are alſo held faſt by two other clamps, to the middle of the verge, as may be ſeen in *fig.* 1; the ſuperior end of the ſtraight vertical part of each tube is open to admit the preſſure of the atmoſphere on the mercury, which is now ſeen ſtanding at the ſame level in both the upright portions of each thermometer, after the inferior or horizontal connecting part is filled; but the bulbs and parts above the letters D, and E, are filled at a mean temperature with alcohol, reſpectively reſting on the columns of mercury: when the balance and balance-ſpring are enlarged by heat, the alcohol has alſo its bulk increaſed, and deſcends below the letters D and E, for inſtance, in very high temperatures as low as the horizontal connecting part, in which caſe the mercury preſſed upon by it deſcends under the alcohol, but aſcends in the ſame proportion at the other end, till it reaches nearly the open ſuperior end of the vertical ſtraight part of the tubes reſpectively; the mercury which was before in a column parallel to the verge, but at a diſtance from it, is now alſo parallel but contiguous, and, as it is a ponderous fluid, the momentum of the balance is conſiderably diminiſhed by the approach of the mercury to the centre of motion, which change of poſition of the mercury conſtitutes the compenſation required to balance the effect of an enlargement of the balance itſelf, and of an elongation of its regulating ſpring taken jointly: in a low temperature the contrary change takes place in the ſituation of the mercury, for as the bulk of the alcohol contracts and retires round the acute angular point into the bulb, the exterior vertical branch becomes filled by the mercury. Peter le Roy, we have before ſaid, was diſpoſed to prefer this balance to the balances he made entirely of metal, but the frangibility of the bent tubes, and the liability of the fluids to be agitated, if not to be mixed, ſometimes conſtituted objections to its portability, that prevented its being copied by other chronometer makers. The adjuſtment for the extremes of temperature muſt have been made by varying the quantity of mercury in a given tube; and probably tubes of various dimenſions were tried ſucceſſively before the exact effect was produced, both at the extremes, and at all the intermediate degrees of temperature. The balance being heavy, was ſuſpended by a thread above the ſuperior end, A, and the ſlender cylindrical part, underneath the ſame A, rotated in a triangular hole, made by three ſurrounding friction rollers, not ſhewn in our figure; laſtly, two regulating ſprings, wound in contrary directions, were placed under the ring, C, near the lower pivot of the verge, which ſprings are purpoſely left out, that the reader may not have to view more parts than are neceſſary for explaining the compenſation balance itſelf.

Compound metallic Balance of P. le Roy.

Peter le Roy, however, was not content with trying his thermometrical tubes, only to effect a compenſation on the balance, but he ſo far adopted Harriſon's idea on the requiſite conſtruction of a balance, carrying its own compenſation in motion, that he tried moreover his compound bars of ſteel and braſs, not, indeed, as curbs, applied to the ſprings according to Harriſon's method, but as rims to the balance itſelf: *fig.* 3 of *Plate* XXIX. ſhews a balance of this contrivance, where A is the diametrical bar fixed to the verge, and BB and C C two ſeparate ſemicircular portions of the compound rim, which were each compoſed of laminæ of ſteel and braſs reſpectively rivetted together in different places, in ſuch a way that the braſs pieces were the exterior or concave ones, and the ſteel pieces the interior or convex ones; the loads are not given in the drawing, but the inventor ſays "Memoire ſur la meillure maniere, &c." that his contrivance made a conſiderable portion of the circumference to approach the centre of the balance in a high temperature; ſo that either he muſt have had loads on the ends of the ſemicircular parts of the rim, or otherwiſe theſe parts themſelves muſt have been thick, which would prevent their due obedience to the variations of temperature. *Fig.* 4 is a kind of regiſter contrived to examine the law by which the flexure of a compound bar was guided, as compared with a mercurial thermometer, thus; A is the croſſes and rim of a balance of one metal, ſteel, we will ſuppoſe, and the compound piece B, ſcrewed at the end *a*, to the plane of the rim, has its end, *b*, at liberty to obey the changes of temperature; near *b* is a ſmall cock into which a roller, bearing the index C, is pivoted above, againſt which roller the free end, *b*, of the compound bar, B, acts, whilſt the interior end of the index points at the diviſions made on the portion of a circle, D, near the centre of the balance: the experiments that were made with this inſtrument, according to P. le Roy's account, ſhewed that the rim of the index, ſo circumſtanced, correſponded very well with the rim of a mercurial thermometer, in all the different parts of the ſcale; and if this was found to be really the caſe, we cannot help thinking it extraordinary that the contriver of the compound metallic balance, which has ſtability and portability to recommend it, did not prefer it, in actual practice, to the mercurial balance, which was liable to the objections we have ſtated.

Arnold's Balances.

Some pains have been taken to prove that Mr. Arnold, ſenior, did not invent his compenſation balances himſelf, but borrowed them from Peter le Roy; we confeſs that we have not met with any concluſive argument in favour of ſuch a ſuppoſition, but, on the contrary, have aſſerted under our article CHRONOMETER, that, "a variety of different ſhapes were given by Arnold to his balances, and actually tried in practice, before he adopted the one in preſent uſe, ſome of which balances are yet in exiſtence;" and we have it now in our power to ſay further, that many of the balances here alluded to are yet in uſe, as ourſelves have witneſſed very lately; which balances have been proved to be excellent regulators, and ſome of which have public teſtimonies in their favour. We propoſe therefore now to deſcribe them in ſucceſſion, or at leaſt ſuch of them as have fallen in our way.

No. 1. In his preface to his printed certificates, Mr. Arnold, ſenior, ſays, that his firſt attempt to improve clocks and watches commenced in the year 1764; but we find it was not till the year 1767, that he turned his mind ſeriouſly to the conſtruction of chronometers; the firſt compenſation balance that he actually brought into uſe, was the one repreſented in *fig.* 5. of *Plate* XXIX. which was taken from one of the original balances while in our poſſeſſion. The rim is 2.4 inches in diameter, and is, together with the three radial arms, of ſlender braſs: the compenſation bar is of braſs and ſteel coiled round the balance verge, at a little diſtance from the mechaniſm which lies between it and the plane of the balance; the exterior part of this compound ſpiral bar is braſs, and the interior part ſteel; *a b* is a piece of ſteel moveable round a tube ſurrounding the balance verge, and having a longitudinal aperture or ſlit, each way from the centre to nearly each extremity, *a* and *b* reſpectively; the end, *a*, is turned up a little, and has the exterior end of the compound ſpiral bar of compenſation attached to it, ſo as to partake of its motion under all the changes of temperature; *c d* and *c d* are two bracket pieces of metal carrying each a pin under them, that exactly fit the longitudinal ſlit of the piece, *a b*; conſequently theſe bracket pieces alſo partake of the motion produced by the compound ſpiral bar; the ends, *c* and *c*, of the bracket pieces are attached to the balance rims at the points, *e* and *e*, by the ſtraight ſlender ſprings, *e c*, and *e c*, reſpectively; to the ends *d* and *d*, of the ſaid brackets are attached the long pins, *d f* and *d f*, which paſs through the ſmall ſteady bridges on the rim, and carry the ſectoral loads of temperature, *f* and *f*; the action produced on this mechaniſm by the changes of temperature may be thus explained; when the temperature is elevated, the exterior end of the compenſation ſpiral bar, moves in a direction from *a* towards *c*, and carries with it the end, *a*, of the croſs-piece, *a b*, at the ſame time the oppoſite end of this piece moves from *b* towards the *c* which is contiguous to it; theſe oppoſite motions of the ends, *a* and *b*, of the croſs piece carry the two brackets in ſuch direction that the loads of temperature, *f* and *f*, are both made to approach the balance, ſo as to leſſen its momentum when in motion; which is the effect required in the above-named temperature; on the contrary, when the temperature is low, the motion of the ends, *a* and *b*, is towards *d* and *d* reſpectively, and the loads of temperature are thrown outwards, to increaſe the momentum of the moving balance. The quantum of effect is regulated by enlarging or diminiſhing the loads, *f*, *f*, of temperature, as compared with the ſcrews, *g* and *g*, or weights of adjuſtment for mean time; or otherwiſe, by ſcrewing them into a new ſituation, out or in, as the caſe may be; the ſprings, *e c* and *e c*, do not interfere with the inward and outward motions of the loads of temperature, but only confine the brackets to the plane of their action, and limit the direction of their motion. This compenſation-balance was applied to ten or twelve different chronometers, between the years 1775 and 1778, but we have not been able to aſcertain its comparative merit; its principle is ſimple, in that there is but one compound bar, to move two loads of temperature, but its mechaniſm is complex, which was probably the principal reaſon why it came into diſuſe.

No. 2. The next balance, which Mr. Arnold contrived, was that which is repreſented in *fig.* 6. of *Plate* XXIX, in which the mechaniſm is much more ſimple than in its predeceſſor; the rim and diametrical bar, by which it is attached to the verge-collet, are both ſteel, the parallel bars, *a b* and *a b*, are compoſed of braſs and ſteel reſpectively, the braſs being here interior and the ſteel exterior, and are inſerted into pivot-holes made in the rim of the balance; in ſome of the chronometers, the end, *b*, was faſt to the balance, and the end, *a*, of the ſame bar looſe, while the end, *a*, of the other bar was faſt, and the end, *b*, of the ſame was looſe, but in other chronometers both the ends of each bar were formed into pivots with ſhoulders, and were inſerted looſely by bending the bars about the middle; the croſs pieces, *c* and *c*, which carry the loads of temperature, are of ſteel, and the rim itſelf is ſo notched as to admit of the loads being contiguous, that they may meet with very little reſiſtance from the air, when in motion; the mode of action is obvious from a view of the figure, and from what has been previouſly ſaid of a ſtraight compound bar, being liable to become convex on the braſs ſide by an elevated temperature, and the reverſe in an oppoſite temperature; the bars, *a b* and *a b*, becoming convex, with increaſed heat, towards the centre of the balance, draw the loads, *d* and *d*, nearer to the rim, than they are when the bars are ſtraight at a mean temperature, and, on the contrary, as the heat diminiſhes, the ſame parallel bars become convex on the ſides next the rim, and carry the loads from the balance; and theſe alternations of motion, keeping pace with the changes made in the dimenſions of the balance itſelf and of the balance-ſpring, conſtitute the compenſation for the effects of temperature: the exact quantum of effect is adjuſted as before, by altering the magnitude of the loads, *d* and *d*, as compared with the weights of the adjuſtment-ſcrews, *e* and *e*, for mean time; or otherwiſe have their relative poſitions altered in regard to their diſtances from the centre. About twenty of theſe balances were made and applied as regulators, all of which performed their office, we are told, very well; the famous gold chronometer, No. 36, tried for 18 months by Dr. Maſkelyne, at the Royal Obſervatory, while worn in the pocket, under the different degrees of temperature, agitations of the body, and changes of poſition, had, and ſtill has, one of theſe balances; and its rate, which has been publiſhed, eſtabliſhed its credit ſo highly, that it was ſold for 1000 *l.* or guineas, notwithſtanding the detent of its eſcapement, after the faſhion adopted by the French, is fixed to an arbor revolving on pivots. The balances of the preſent conſtruction were made from the year 1778 to the year 1780, and the only objection we have heard alleged againſt them, was the play they neceſſarily had in their pivot-holes, which we think muſt have been ſcarcely perceptible when the pivots were well made and fitted tight into their holes.

No. 3. The objection to the motion at the pivot holes in the laſt balance, (No. 2.) was attempted to be remedied by the conſtruction exhibited in *fig.* 7. of the ſame plate, where the expanſion pieces are of braſs and ſteel, arranged in the form of a long S, which form was afterwards adopted by Emery, the Swiſs watch-maker, who ſettled in London, and who has been the reputed inventor of this arrangement; the two halves of the S are joined at the middle, and the braſs, as before, is interior throughout; the rim and diametrical bar of ſteel, in the balance we examined, which was 1.2 inches only in diameter, by reaſon of its having been uſed in a pocket-chronometer; the exterior end, *a*, of the S is attached to one of the ſhortened croſſes of the balance, and the interior end of the ſame bears the long pins, *c* and *c*, that carry the loads of compenſation *d* and *d*; the long pins, *c* and *c*, do not paſs through the rim, but are held to their proper poſitions by the two ſlender ſprings, *e c* and *e c*, as in No. 1, or *fig.* 5: as before, the relative weights of the loads of compenſation, *d*, *d*, and *f*, *f*, the loads of adjuſtment for mean time, conſtitute the limit of effect to be produced by the expanſion bars, ſuppoſing their diſtances from the centre fixed; but if the loads remain unaltered, the effect to be produced may be adjuſted by varying the diſtances of the ſcrews reſpectively as they regard the centre of the balance. Of theſe balances about forty were made and applied to uſe between the years 1779 and 1782, and have been found to perform well.

No. 4. The length of the S pieces in the laſt balance having been found difficult to execute of uniform thickneſs and ſhape, by reaſon of their great length, the conſtruction repreſented by *fig.* 8. was ſubſtituted, which is very nearly allied to its predeceſſor, and indeed differs from it only as the bends are united by an interpoſed piece of ſolid metal, thereby dividing what was before one half of the S, into two parallel compound bars; in all other reſpects, the deſcription juſt given of No. 3, together with the letters of reference, will equally apply to our preſent balance; which circumſtance renders a further detail ſuperfluous.

Of theſe balances not more than ſix or eight were conſtructed, by reaſon of the more ſimple form, which is now in general uſe, having been adopted in 1782, when a patent was taken out for it. The ſpecification, however, contains the drawings of Nos. 2 and 3 (*figs.* 6 and 7), as well as of the common balance, which we have fully deſcribed under our article CHRONOMETER, to which the reader is reſpectfully referred, and which was known to the workmen by the name of the Z balance, by way of diſtinction from the S balance. Beſides the above-deſcribed conſtructions of the compenſation balance, Arnold, we are aſſured, contrived various others which never came into uſe, one of which had the expanſion pieces parallel to the verge of the balance, and borne by it; and others had platina in the expanſion pieces, inſtead of ſteel; but we conceive it to be unneceſſary to purſue the ſubject of his inventions further, than merely to obſerve, that ſo regular a ſucceſſion of different balances actually made and uſed, where ſo many were conſtructed, and where each was evidently meant to be an improvement on the laſt preceding, may be taken, if not as a poſitive, at leaſt as a preſumptive proof, that the imputation of plagiariſm, unleſs otherwiſe fairly made out againſt him, is in contradiction to the facts we have here adduced; which are all facts open to ſtill further inveſtigation.

For the deſcription of the compenſation-balance as made by the Brockbanks and Earnſhaw, the reader is deſired to turn to the article CHRONOMETER, where this part of our preſent article has been anticipated. The deſcription of Earnſhaw's balance and eſcapement, however, which we have quoted as the production of this chronometer-maker, it may be proper to ſtate, was not his, but the production of Mr. Firminger, the late aſſiſtant of Dr. Maſkelyne at the Royal Obſervatory, as we have been aſſured by the author himſelf, ſince the publication of the pamphlet in which it appeared oſtenſibly as Mr. Earnſhaw's own account. And now that we are on the ſubject of Mr. Earnſhaw's balance and eſcapement, we beg leave to add further here, an acknowledgment of our miſinformation reſpecting the patent, which we were credibly informed, and ſaid, was never taken out; but which we now find, on more minute examination, was actually taken out and regiſtered. How far his pretenſions to originality of invention are warranted by his conſtruction, is not the object of our preſent enquiry.

A Compenſation balance by F. Berthoud.

Berthoud informs us, "Hiſt. de la Meſure, &c." p. 104 tom. ii., that he had propoſed a means of compenſation by the balance itſelf, ſo long ago as in the year 1754; but that it was not until 1787 that he effected his purpoſe. The reader is led to ſuppoſe, that he was not indebted to P. le Roy, or any other maker, for the contrivance, but that it was the reſult of his own inventive genius; and that the contrivance was his own is rendered ſomewhat probable from this conſideration, that in his "Traité des Horologes Marines," two balls only were propoſed to be uſed with two compound bars; but after a calculation of the effect to be produced, contained in page 195 of the Supplement, four balls were found to be neceſſary with as many compenſating bars. The propoſed arrangement is ſhewn in *fig.* 9. of plate XXIX, and is certainly original; A, A, A, and A are four radial bars of metal attached to the verge collet of the balance by two ſcrews, as ſeen in the figure; the ſlender bars, *a*, *a*, *a*, and *a*, attached reſpectively to the exterior ends of the four radial bars by ſcrews and fixing pieces, are four compound bars of ſteel and braſs, the exterior laminæ being of braſs; and each of thoſe compound bars has at its free end a ſtem formed into a ſcrew, upon each of which a ball, B, with a long ſocket, ſcrews towards or from the verge, to adjuſt the momentum to the maintaining power, and regulating ſpring, and alſo to effect the equilibrium, when the machine is brought to time. From what we have repeatedly ſaid of the flexure of a compound bar, it is eaſy to ſee, that the braſs portions being exterior, will cauſe the balls to approach the centre of motion in hot weather, and the reverſe in cold; which effect conſtitutes the compenſation. The author acknowledges that the exact effect to be produced depends on the relative length and thickneſs of each compound bar, and that many trials are neceſſary to come at the due proportion; conſequently, the want of an adjuſtment for temperature, after the balance is tried, is in this conſtruction a fundamental objection to its general adoption; otherwiſe we ſee no reaſon to doubt its accuracy of performance.

This balance was uſed in No. 8. of Berthoud's marine pieces.

Another Compenſation-balance by F. Berthoud.

The compenſation-balance which we have juſt deſcribed being found liable to objection, the ſame author contrived and uſed, in his No. 63, a different arrangement of the compenſation bars, which he again reduced to two, and introduced two additional ſcrews for adjuſtment of mean time, placed at right angles to the former; the contrivance is ſhewn in perſpective in *fig.* 10. of *Plate* XXIX., where all the eſſential parts may be viewed at once: A A is the balance, made light and of the beſt braſs, having four croſſes; B and B are the two compenſation bars fixed to the rim of the balance at one end, and bearing the ſcrews or weights of temperature, C and C, at the other reſpectively; and D and D are the ſcrews or weights of adjuſtment for mean time, borne by two of the oppoſite croſſes, as ſhewn diſtinctly in the figure. The balance as uſual is attached to the verge collet by a couple of ſmall ſcrews; the exterior laminæ of the two compound bars, B and B, are of braſs, and the interior ones of ſteel, ſo that a high temperature brings them towards the centre of motion, as the balance itſelf enlarges, and as its ſpring elongates and becomes weaker. The adjuſtment for temperature may be made in two ways; either by altering the relative ſizes of the ſcrews of temperature and ſcrews of mean time; or otherwiſe, which is more readily done, by ſcrewing one pair in and the other out, ſo as to produce a ſimilar effect without taking either of the pairs entirely out; it is hardly neceſſary to explain that, in all the conſtructions, when the momentum of the balance conſiſts more of the moving weights of temperature, than of the moving weights of mean time, the effect of the compenſation bars will be the greater in the ſame proportion, and the contrary; ſtill, however, the quantity of flexure of the compound bars in the preſent balance remains unaltered, and conſequently the velocity of their inward and outward motions is not capable of adjuſtment in any other way, than by altering the ratio of their length to their thickneſs reſpectively, which may be called an alteration rather than an adjuſtment.

Compenſation balance by Joſias Emery.

We have ſaid, under our article Chronometer, that Emery's balance is one of the varieties previouſly contructed by the ſenior Arnold, (ſee his N° 3.) and the reader will now judge for himſelf how far our aſſertion was founded in fact. We take our drawing from Berthoud's figure of Emery's balance, which Sarron took over into France, and which was much admired for the accuracy and permanency of its regulation. *Fig.* 11 of *Plate* XXIX, preſents the plane of Emery's balance to the eye placed over it; A A is the balance made with four croſſes, the rim of which is braſs; B B is a ſteel flat ring ſcrewed to two of the croſſes; C and C are the two compenſation bars, each bent twice over into the ſhape of a long narrow S; D and D are the weights for mean time, formed into adjuſting ſcrews to ſuit the female ſcrews of the protuberances made on the plane of the balance; the ſcrews, E and E, are the adjuſtable weights for temperature, but are tapped only at the parts neareſt their heads; the points being faſt to the exterior ends of the compound bars, and the intermediate pins being without threads and moving ſteadily in the two ſockets reſpectively fixed to the rims, or rather formed out of them in the ſolid; the S pieces have the braſs laminæ as uſual on the exterior ſides, ſo that at the middle of the S of each compound bar, the poſition begins to be reverſed, in order that the condition may be fulfilled; the interior end of each compound bar preſſes againſt the circumference of the ſteel ring B B, which we have ſaid is faſt to two of the croſſes; conſequently, whenever a change takes place in the temperature of the parts, the whole motion takes place at the foot of the ſcrew of temperature, at each oppoſite ſide of the balance. The ſmall interior circle F is the upper end of the cylindrical ſpring of the balance, together with the pin that holds one end of it, and the part that forms the banking, which have nothing to do with the compenſation. In this balance, as in Berthoud's latter one, the adjuſtment for temperature muſt neceſſarily be made, by altering the relative momenta of the ſcrews of mean time, and of the ſcrews of temperature.

Mr. W. Hardy's Compenſation-balance.

Among the moſt recent improvements in chronometry, may juſtly be reckoned the new compenſation-balance of Mr. W. Hardy of Clerkenwell, communicated to the Society of Arts in the Adelphi, in March 1805, and renumerated with thirty guineas. The balance in common uſe, that brings the weights of temperature alternately towards and from the verge, by ſimple flexure of the compound rim-pieces, is objectionable, in the opinion of Mr. Hardy and others, on account of theſe conſiderations: 1ſt, The two metals of the compound pieces of the rim, when united by fuſion of the braſs, are liable to partial ſeparations, which affect the permanency of the adjuſtment for temperature; 2dly, The variation of the centrifugal force of the weights of temperature in large and ſmall arcs of vibration overpower the elaſticity of the expanſion pieces, and affect the momentum of the balance, as adjuſted for mean arcs of vibration; the weights being thrown from the centre more in the long arcs than in the ſhort ones; and, 3dly, The adjuſtments for rate and temperature, however carefully made, will affect the equilibrium of the balance, and the rate of the machine placed in different poſitions, without ſubſequent rectifications; to remove theſe objections, Mr. Hardy has availed himſelf of the direct expanſion of two different metals, where their difference of expanſion produces a mechanical action on the loads of temperature, ſuch as bids fair for general introduction in practice.

Fig. 3. of *Plate* XXX. of *Horology*, exhibits a lateral view of the balance before us, and *fig.* 4. the balance inverted; A A is the balance arbor or verge of the ordinary conſtruction; B B is a ſteel diametrical bar, borne by the collet of the verge, 1.6 in. long, 0.232 broad, and 0.032 thick; this ſteel bar is made uniformly except at the two extremities, which are made narrow, and in each of which a notch is cut in the inferior ſurface, ſo far, that the remaining thin metal conſtitutes a ſpring above each notch; beyond theſe ſprings, which we have ſaid form a part of each end of the diametrical bar of the balance, are attached two ſtems at right angles, ſo as to be parallel to the verge when the ſmall ſprings are not acted on by any force; the upper parts of the ſtems, in the original drawing, are formed into ſcrews with threads adapted to the tapped holes of the two balls C, C, which they ſupport, and which are weights of adjuſtment for temperature, but in our more recent drawing, the weights ſlide and are fixed by ſide ſcrews; D, D, are two ſimilar ſcrews for rate which ſcrew reſpectively into the inferior or thicker parts of the ſtems, ſo as to be capable of increaſing or diminiſhing the effective momentum of the balance according to circumſtances; and E, E, are ſcrews of adjuſtment for equilibrium; each end of the ſteel diametrical bar has, moreover, a ſtud or ſhoulder, pointing downwards under the ſtem juſt deſcribed, which ſtud cannot be ſeen in the figure in a ſeparate ſtate; underneath the ſteel bar, and exactly parallel to it and to each other, are placed two bars of braſs, ſhorter but broader than the ſteel bar; the length of each is 1.47 in, the breadth 0.078, and the thickneſs 0.032, like that of the ſteel; each of the two braſs bars has one of its ends ſecured to one of the ſtuds deſcribed, and preſſing with its oppoſite end againſt the other, but in ſuch a way, that their poſitions are reverſed with reſpect to the fixing of the ends; the fixed end of the one being contiguous to the free end of the other reciprocally; a ſecond view is given of theſe bars in *fig.* 4, where they are repreſented in an inverted ſtate. The action of the mechaniſm it is not difficult to underſtand, though the author has rendered his account ſomewhat confuſed by his mention of ſhort levers, which the reader does not ſee in the figure. When the balance is expoſed to heat, the ſteel bar elongates a little both ways from the verge in the centre, but the two braſs bars ſeparately elongate more, and conſequently each detached end, having liberty to move a quantity equal to the difference of the two expanſions, puſhes againſt the ſtud or ſhoulder that is contiguous, and forces it outwards; the ſlender ſpring-parts, above the notches of the ſteel bars, now yield to the forces impreſſed reſpectively on the ſtuds, and the parts of the two ſprings which yield moſt may be conſidered as centres of motion of a pair of levers; the diſtance from the yielding point of each ſpring to the point urged by the detached end of its braſs bar, may be called the length of the ſhort end of each lever, and the diſtance from the ſaid point of each ſpring to the centre of the load carried by the neareſt ſtem, may be taken as the length of the long end of the lever, which two ends ſuppoſe as 1 to 20 reſpectively; then if the difference of the expanſions of the ſteel and one of the braſs bars be called 1 outwards, the quantity of inward motion in the ſame denomination will be 20; conſequently, the ſame heat which elongates the ſteel bar, and carries the balls from the centre of motion, will, at the ſame time, by the exceſs of expanſibility of the braſs bars, bring the ſame balls inwards towards the ſame centre, and the two contrary actions may be adjuſted, by moving the loads up or down their proper ſtems, till theſe oppoſite effects exactly balance one another; for as thoſe diſtances that have been denominated the ſhort ends of the levers are variable in length, or very nearly ſo, varying the longer ends only, *viz.* the diſtances of the balls from the yielding points of the ſprings, conſidered as centres of motion, will alter the ratios, which may be done in the requiſite proportion, till the compenſation is found in the tentative adjuſtments to be perfect. When once the exact compenſation is effected, it is obvious, that the law by which it is preſerved is uniform and conſtant, as that according to which the grid-iron pendulum is conſtructed, which experience has proved to be permanently uſeful in practice. When the balance has its momentum properly adjuſted for rate, with a given maintaining power, eſcapement, and balance-ſpring, and when the balance is put into an exact ſtate of equilibrium, the ſtems being at all times either exactly parallel to the verge, or, if inclined a little by the extremes of temperature, alike inclined, it is ſelf-evident, that, under theſe reſtrictions, the adjuſtment of the loads up or down for temperature will not deſtroy the adjuſtments of rate, and of equilibrium for the poſitions, previouſly made, provided the two loads be of equal weight, and placed in ſimilar poſitions on their reſpective ſtems; and even if one happen to be left a little higher on the ſtem than the other, no ſenſible bad effect will be produced thereby, which circumſtance is one of the greateſt recommendations of the preſent balance. The effects produced by variations of temperature, are ſaid to be produced not by jerks, but regularly, notwithſtanding the united ſtructure of the parts is ſufficiently firm; and, laſtly, the conſtruction is ſo ſimple, that a common workman may ſucceed in making and putting together the conſtituent parts of this balance without difficulty.

Compenſation on the Balance and alſo at the Spring.

Double Compenſation by Berthoud.—F. Berthoud having experienced much inconvenience, and loſt much time in making the adjuſtments of his balances for rate, temperature, and poſition, at length determined to avail himſelf of the curb, as a ſupplemental aid, in addition to the compenſation carried by the balance itſelf; the union of the two modes of effecting the due compenſation, is repreſented in *fig.* 5 of *Plate* XXX. of *Horology*, in ſuch a way that all the acting parts may be ſeen and underſtood: A is the balance-rim of braſs, and bears four croſſes, beſides two projecting bars, B, B; theſe bars carry each a compound or compenſation bar, C, of the uſual conſtruction, the free ends of which are perforated and attached to the ſcrews or loads of temperature, D and D, or, more properly ſpeaking, to the ſliding ſockets on which thoſe loads ſcrew in and out, in making the adjuſtment; E and E are the ſcrews or loads of adjuſtment for mean time: FF is the cock, and G a ſmall cock, bearing a jewel mounted on it, to take the pivot of the balance. The action of the compenſation bars, C and C, needs no explanation, after what we have ſaid about the effect of ſuch pieces borne by other balances: I, is the compenſation bar of the curb for the ſpiral ſpring, ſhewn in the figure, and acts on the bent ſteel bar, K, which holds the curbing pins, and which has its centre of motion under the cock, at a ſhort diſtance from the balance-verge; the quantity of action of I on K is regulated by the holding piece, *a*, ſliding in a dove-tailed groove, between the parallel bars, *b* and *b*, ſcrewed to the piece N, which piece, N, is moveable round a pin under it, near the part, *a*, in ſuch a way as to admit of a little circular motion, together with the compound bar, I, to regulate for mean time without altering the length of I; and a ſlow motion may be given to the piece, N, by the graduated piece, M, which is moveable on the pivots of its arbor, in the plate and ſmall cock, L, while the tooth, or rounded part, lies in a concave part at the end of N, and impels it almoſt imperceptibly as the end, M, moves; the graduations of the piece, M, are ſeen through a hole made in the interior caſe of the watch; and the adjuſtment for rate may be made there without trouble, and without deranging the previous adjuſtments of the balance itſelf; but then, if there is an iſochronal point in the acting length of the ſpiral ſpring, the adjuſtment made by means of the curb will derange its iſochroniſm, which will become ſenſible as the arc of vibration varies in uſe; otherwiſe the adjuſtment for temperature might be completed by varying the length of the compound-bar, I, after this adjuſtment has been nearly effected on the balance itſelf, and after the balance has been brought into a ſtate of equilibrium for the poſitions; but whether the effect produced by the joint agency of two cauſes, will be uniform in all degrees of temperature, has not been ſaid by the author.

Compenſation for the Spring's want of Iſochroniſm.

That property of a balance's regulating ſpring which makes the balance perform all its vibrations, long, ſhort, and intermediate, preciſely in the ſame time, is called its *iſochronal* or *iſochronous* property, from the two Greek words ισος, *equal*, and χρονος, *time*: it has been aſſerted that there is a certain proportion between the length and thickneſs, or between the length and the breadth and thickneſs taken conjointly, which only aſcertains the iſochronal point in any uniform ſpring, of whatever ſhape; this doctrine has been maintained by Dr. Hooke and Peter le Roy ſeparately, and has been ſubſcribed to by Arnold the ſenior, Berthoud, and others, though Pennington of Camberwell ſays there are different points in the ſame ſpring equally iſochronal; now allowing that there is only one point in the length of every ſpring that determines its iſochroniſm, and that conſequently all other lengths of the uniform ſpring regulate the balance uniformly, only while the arcs of vibration remain unchanged, to determine the iſochronal effective length of ſuch ſpring would be to render all compenſations, for want of iſochroniſm, unneceſſary; and this point may in moſt ſprings be aſcertained by repeated trials with long and ſhort arcs ſucceſſively, and by marking down the reſpective reſults; for it is found from experiments, that if ſhortening the regulating ſpring makes the long arcs of vibration to be performed in leſs time than the ſhort ones, and *vice verſâ*, the ſpring under trial is capable of having its total length reduced gradually till the iſochronal length is determined, but, generally ſpeaking, not otherwiſe. Another method of managing the ſpring, which may be ſaid to be effecting a ſpecies of compenſation for want of iſochroniſm, in the total length of an uniform ſpring, is tapering it from the outer to the inner end, till, with a given length, the long and ſhort arcs are performed in equal times; this method was ſtrongly recommended by Cumming in his Eſſay towards the improvement of watch-work, and after him, Earnſhaw has laid much ſtreſs on this particular, ſo much indeed, that he conſiders his ſkill in the adjuſtment of the iſochroniſm, by a tapering ſpring, as conſtituting one of his chief claims to public encouragement; nay, he profeſſes to manage the buſineſs ſo nicely, that he can make ſuch a ſlight deviation from perfect iſochroniſm as will compenſate the *laſſitude* alſo, in the intenſity of his ſprings in uſe!

The firſt notice that we have of a regular compenſation, for want of perfect iſochroniſm in a regulating ſpring, is Harriſon's, when he propoſed to introduce the cycloid-pin which we have already confeſſed we do not underſtand, from the want of ſhading in the drawing of it, as attached to his compenſation curb, in the publication by the Board of Longitude; we may, however, ſtate, that Harriſon, not knowing, probably, that there is naturally an iſochronal length in moſt uniform ſprings, concluded, that the long arcs are naturally performed in leſs time than the ſhort ones, reaſoning from the circumſtance of one of his pieces having been obſerved to go faſter in a horizontal poſition, than in a vertical one, though the arc of vibration was ſhorter in the latter than in the former poſition; he therefore applied his cycloid-pin, as Mudge did after him, as may be ſeen in the drawing of his eſcapement, in ſuch a way that the ſhort vibrations were accelerated by its puſh more than the long ones, that were not ſo long acted on by auxiliary means; but the fact is, the uſe of ſuch a contrivance would neceſſarily have an effect juſt oppoſite to the intended one, if the balance-ſpring happened to be pinned to the ſtud at the contrary ſide of the iſochronal point; that is, if the long vibrations were ſlower than the ſhort ones, the cycloidal contrivance would make the difference ſtill more ſenſible.

Berthoud's Compenſation for want of Iſochroniſm.

Berthoud has given an ingenious method of compenſating the want of iſochroniſm in a balance-ſpring in his "Supplement au Traité des Horloges Marines," which contrivance he calls an *iſochronal compenſator.* (Compenſateur Iſochrone.) The contrivance is repreſented in *fig.* 6. of *Plate* XXX, where A repreſents the balance with three radii; B an eccentric collet of poliſhed ſteel, placed on the balance-verge, and preſſing againſt the large roller C, which is carried by and pivoted into a ſmall frame at the end of the ſlender ſpring D, attached to the cock, E, on the plate of the watch frame, whenever the long vibrations are found by trial to be performed in a longer time than the ſhort ones, the poſition of B and C are reſpectively as in the drawing, at the time when the balance-ſpring is quieſcent; for then the preſſure of the eccentric piece, B, againſt the roller urged by the ſpring, is greater in the ſmaller arcs than in the long ones; but when the long arcs are performed in the leaſt time, the poſition of B muſt be at *b*, and then C will be found by the force of its ſpring at *c*, where it is evident, that the preſſure will be leſs in the ſhort arcs than in the long ones comparatively; and the quantity of eccentricity of B muſt depend on the greateſt difference of the two extreme vibrations. The principal reaſon why Berthoud adopted this iſochronal compenſator in five clocks, and in his portable watch for the longitude, was, that whenever the cock was diſmounted the iſochroniſm of his ſpring, however well adjuſted, was generally found to be deranged when re-mounted. The eccentric collet was of courſe capable of being put to any given eccentricity as well as into any given poſition for accelerating long or ſhort arcs at pleaſure. The Engliſh watch-makers have not, that we know of, ever uſed this contrivance, but depend on their own patience and ſkill, in aſcertaining the beſt length and moſt deſirable ſhape of their regulating ſprings for effecting their own purpoſe.

Mr. W. Hardy's Compenſation for want of Iſochroniſm.

Mr. W. Hardy publiſhed a ſhort account of a new method of making the balance of a chronometer perform its long and ſhort vibration, in the ſame time, in Mr. Nicholſon's Journal for September, of the year 1806. (Supplement of vol. xiv. 8vo. Series) which account, we propoſe, to copy with ſome ſlight verbal deviations, that are more adapted to our figures, as drawn in perſpective. The ſpring *a b*, *fig.* 8 of *Plate* XXX, is ſcrewed to the inferior ſide of the cock A, *fig.* 7. and lies over the upper part of the regulating-ſpring, proceeding in a right line to the axis of the balance B, and having a bend to clear the verge, from which it paſſes on to the end of the ſpring which it holds. This ſtraight ſpring is made of ſuch a ſmall ſtrength, that it comes into action before the regulating ſpring. The other piece *c*, *fig.* 8, is attached to the cock, in a line with the ſlender one, but on the oppoſite face of the cock; the part of the piece, *c*, which is bent down, is divided into a fork and admits the part, *b*, of the ſlender ſpring, to paſs and play between its prongs; at each ſide of the prongs is a lateral ſcrew, preſenting its point to the ſpring, in ſuch a way, that the play between the prongs, or rather between the points of the two equidiſtant ſcrews, may be limited according to circumſtances, provided they are not farther aſunder than the quantity of the eſcapement angle. The other end of the cylindrical regulating ſpring, as uſual, is attached to a piece of metal carried by the verge of the balance. The effect produced by the compenſating ſpring, *a b*, is thus; when the balance is firſt moved from its place of reſt, the ſlender ſpring, *a b*, moves firſt, till it meets with the point of one of the two ſcrews of the fork, then the cylindrical-ſpring begins to be acted on, as in the chronometers in general; this motion of the ſtud, at the end of the ſlender ſpring, retards the motion of the balance, which begins to be accelerated only, when the ſtud is at reſt; conſequently the contrivance before us ſuppoſes that the ſhort arcs are in general performed in leſs time than the long ones; and require on that account, to be checked in their velocity at ſtarting; and the quantity of play in the fork limits the quantum of retardation; but as we have ſeen the long arcs may be, and often are, performed in leſs time than the ſhort ones, with ſprings not adjuſted for iſochroniſm; we conceive, therefore, that, like Harriſon's cycloid pin, which owed its origin to a contrary ſuppoſition, the application of the invention we are deſcribing may happen to be productive of an effect, juſt oppoſite to that which it is meant to produce; for it can be uſed as a compenſation for want of iſochroniſm, only in the particular caſe, when the ſhort arcs of vibration are performed in leſs time than the long ones, which we have ſeen is juſt the oppoſite application of that adopted by Harriſon, and founded, as we have ſaid, on an oppoſite ſuppoſition; whereas the fact is, that ſometimes one of the two contrivances may prove to be neceſſary, and ſometimes the other, with a limited length of ſpring, accordingly as the long, or the ſhort arcs of vibration, may turn out on trial to be performed in the leſs time; and the trial neceſſary for aſcertaining, whether the ſpring is too long or too ſhort, will afford the means of aſcertaining very nearly, if not quite, the exact iſochronal length, ſuch as ſhall require no compenſation at all; to attain which object, though with ſome additional trouble, we are diſpoſed to think the preferable practice.

COMPENSATION-*Pendulum*, is a ſuperior kind of pendulum in which the natural effects of two actions are ſo oppoſed to each other, as to counteract or compenſate each other's influence on the motion of the going pendulum. We have already deſcribed the grid-iron pendulum invented by J. Harriſon, and alſo, Troughton's new arrangement of the metallic bars, under our article CLOCK, to which we muſt here refer; and for the other various conſtructions of a compenſation-pendulum the reader is deſired to conſult the word PENDULUM, where he will find the ſubject treated at conſiderable length.

COMPERTORIUM, in the *Civil Law*, denotes a judicial inqueſt made by delegates, or commiſſioners, to find out, and relate the truth of a cauſe.

COMPETENCE, or COMPETENCY, in *Law*, the authority, or right of a judge, for taking cognizance of any matter. See JURISDICTION.

COMPETENCE *Militaire*, Fr. military juriſdiction. In France, the officer of the troops took cognizance of and poſſeſſed the right of directing the proceſs or proceedings in regard to every thing that concerned military affairs and offences, thoſe excepted, that were puniſhable by the provoſt marſhal, and to judge of all crimes and offences committed by an officer againſt an officer, or by a ſoldier againſt a ſoldier, provided a civil individual had no concern or intereſt in it. And if the civil judges were obliged to cauſe military perſons to be arreſted, the commandants could demand them, and in caſe of refuſal complain to the ſovereign through the miniſter.

COMPETENT *Witneſſes*. See WITNESS.

COMPETENTES, in *Church Hiſtory*, an appellation given to the catechumens, when being ſufficiently inſtructed in the Chriſtian religion they required baptiſm.

COMPEYRE, in *Geography*, a town of France, in the department of Aveyron, and diſtrict of Milhaud; one league N. of Milhaud.

COMPHEDA, a town of Arabia Felix on the Red Sea, S.E. of Mecca, garriſoned by the Turks.

COMPIANO, a town of Italy, in the duchy of Parma; 12 miles from Pontremoli.

COMPIATA, *Ital.* COMPLICS, *Fr.* The laſt prayer or hymn ſung in full chorus, at the end of the ſervice of the Romiſh church.

COMPIEGNE (in Latin, *Compendium*,) a handſome town of France, the chief place of a diſtrict in the department of Oiſe, ſituated on that river at the diſtance of two kiliometres from the confluence of the Oiſe with the Aiſne and 76 kiliometres from Paris. N. lat. 49° 25′. E. long. 3° 12′. A very extenſive foreſt ſtretches from this town to the department of the North and that of the Lys. Before the revolution of 1789 the kings of France reſided occaſionally at the palace of Compiegne to take the diverſion of hunting. This palace was built by Charles the Bald, repaired by ſeveral of his ſucceſſors, and reconſtructed on a grand ſcale in 1755 by Louis XV. There is alſo a beautiful bridge over the Oiſe which formerly was adorned with the arms of France elegantly carved in ſtone by Couſtou: but this fine monument was mutilated in 1793 by a revolutionary ſtone-cutter, who put a cap in its place. Compiegne has a ſub-prefect, two courts of juſtice, and 6359 inhabitants. The diſtrict contains a population of 88,048 individuals, diſtributed in 165 communes. Its principal trade is in wood, corn, and wool. Its wine is much eſteemed. There are but a few manufactures of worſted caps and ſtockings.

COMPITALIA, or COMPITALITIA, feaſts held among the ancients in honour of the *lares*.

The word comes from *compitum*, a *croſs-way*; becauſe the feaſt was held in the meeting of ſeveral roads.

The compitalia are more ancient than the building of Rome. Dionyſius Halicarnaſſus, and Pliny, indeed, ſay that they were inſtituted by Servius Tullius; but this only ſignifies, that they were then introduced into Rome.

Notwithſtanding what Dion relates, that the compitalia were celebrated a little after the Saturnalia, and that the Roman calendar fixes them on the twelfth of January, it appears that they had not fixed any day, at leaſt not till the time of Varro, as is obſerved by Caſaubon.

The feaſt being then moveable, the day whereon it was to be obſerved, was proclaimed every year. It was ordinarily held on the fourth of the nones of February, *i. e.* on the ſecond of that month. Macrobius obſerves that they were held not only in honour of the *lares*, but alſo of *mania*, madneſs. The prieſts who officiated at them were ſlaves and liberti; and the ſacrifice was a ſow. They were re-eſtabliſhed, after a long neglect, by Tarquin the Proud, on occaſion of an anſwer of the oracle, "That they ſhould ſacrifice heads for heads," *i. e.* that for the health and proſperity of each family, children were to be ſacrificed: but, Brutus, after expelling the kings, in lieu of thoſe barbarous victims, ſubſtituted the heads of garlick and poppy; thus ſatisfying the oracle, which had enjoined *capita*, *heads*, at an eaſier rate.

During the celebration of this feaſt, each family placed at the door of their houſe, the ſtatue of the goddeſs *Mania*: they alſo hung up at their doors figures of wool, repreſenting men and women; accompanying them with ſupplications that the *Lares* and *Mania* would be contented with thoſe figures, and ſpare the people of the houſe.

As for ſlaves, in lieu of the figures of men, they offered balls or fleeces of wool. Servius Tullus ordered, that the ſlaves who aſſiſted at the compitalia, ſhould be free during the whole time of the feaſt. Auguſtus ordered the ſtatues of the *Lares*, placed in the croſs ways, to be adorned with flowers twice a year.

COMPLACENCY, in *Pathology* and *Ethics*, denotes full and continued ſatisfaction, connected with a conſiderable degree of approbation. It has intrinſic value, or ſome ſpecies of worth for its object. Some mental excellencies, or advantages accruing from them; ſome ſentiment, diſpoſition, acquirement, conduct, performance, either of ourſelves or of others with whom we are immediately connected, which, upon cloſe examination, we deem deſerving of eſteem or applauſe. Complacency may be enjoyed as the reward of our own conduct, or of the purity and benevolence of our motives; and it may alſo relate to the approved conduct, ſentiments, attainments, and diſpoſitions of others, for whom we are deeply concerned. The ſatisfaction produced by complacency indicates, that we have, in ſome reſpect or other, a perſonal intereſt in the object of it; and the approbation implied in it conveys the idea of ſome kind of excellency. In ſtrict propriety of language, complacency is alone applicable to that ſpecies of good which originates from ſome mental or moral excellence; where there is an indication of propriety, ingenuity, wiſdom, addreſs, or dignity, in ſentiment, deſign, execution, or of rectitude and benevolence in the motive, this affection will poſſeſs different degrees of ſtrength, according to the various kinds and degrees of excellence diſcernible in the exiſting cauſe; and high complacency is the moſt grateful of all the affections. It poſſeſſes an elevation and a ſuavity peculiar to itſelf. It is permanent ſatisfaction, enjoying the full approbation of reaſon; and conſequently it ſuffers no allay from the ſtruggle of contending paſſions, or oppoſite deſires. When it is inſpired by our own conduct, it is accompanied by ſelf-approbation, or the teſtimony of an applauding conſcience, enlivened perhaps by the voice of gratitude, and enriched by the eſteem of the worthy. If it proceed from the conduct of others, it augments the pleaſures of affection, friendſhip, and gratitude. This affection, however, has its counterfeit; and an erroneous opinion of ourſelves may change the nature of this ſublime affection, and render it the parent of vice and folly. Thus falſe conceptions of our own talents, acquirements, and conduct, may inſpire pride, vanity, haughtineſs, and arrogance. Cogan on the Paſſions, p. 71.

COMPLAINANT, in *Law*, a plaintiff, or one who prefers a complaint againſt another, to be relieved by juſtice or equity.

COMPLEMENT, in a general ſenſe, denotes what is wanting, or neceſſary to complete ſome certain quantity or thing.

COMPLEMENT, *Arithmetical*. See ARITHMETICAL.

COMPLEMENT, in *Aſtronomy*, is uſed for the diſtance of a ſtar from the zenith; or the arch comprehended between the place of a ſtar above the horizon, and the zenith. It is the ſame as the complement of the altitude, or co-altitude; or zenith diſtance.

COMPLEMENT *of the courſe*, in *Navigation*, is the number of points the courſe wants of 90 degrees, or eight points; *viz.* of a quarter of the compaſs.

COMPLEMENTS *of the curtain*, in *Fortification*, are thoſe parts of the ſide of the interior polygon, which form the demi-gorges of the two baſtions adjoining the curtain.

COMPLEMENT *of the line of defence*. See LINE *of defence*.

COMPLEMENT, in *Geometry*, is what remains of a quadrant of a circle, or of ninety degrees, after any certain arch has been retrenched from it. Thus, if an arch or angle be 30 degrees, we ſay its complement is 60 degrees, ſince $60 + 30 = 90$.

The ſine of the complement of an arch is called the *coſine*; of a tangent, the *co-tangent*; &c.

We ſometimes alſo ſay the *complement of an angle*; meaning ſo much as it wants of a right angle, or of 90 degrees.

COMPLEMENT, in *Heraldry*, a term uſed to ſignify the full moon, for example, azure, the moon in her *complement*, argent.

COMPLEMENTS *of a parallelogram*, are the two leſſer parallelograms, made by drawing two right lines parallel to each ſide of a parallelogram, through a given point in the diagonal.

Such are the parallelograms C and M (*Plate* III. *Geometry*, *fig.* 50.) It is demonſtrated, that in every parallelogram, the complements C and M are equal: for $Z + C + o = R + M + x$; as making up on each ſide the great triangles, made equal by the diagonal; of which, $Z = R$, and $o = x$ (becauſe the diagonal makes them ſo); wherefore the remaining parallelogram $C = M$.

COMPLEMENT *of life*, in the *Doctrine of Life annuities*, denotes the difference, according to M. De Moivre's hypotheſis, between the age of any given life, and 86 years; thus, at the age of 30 the complement is 56—at the age of 37 it is 49—at the age of 50 it is 36, and ſo on. In this hypotheſis the probabilities of life through every period of exiſtence, are ſuppoſed to decreaſe in an arithmetical progreſſion, ſo that out of 86 perſons juſt born, one is ſuppoſed to die every year, till at the end of 86 years, which is conſidered as the utmoſt limit of human life, the laſt ſurvivor becomes extinct. M. De Moivre, who formed this hypotheſis with the view of facilitating the computations of life-annuities, derived it from Dr. Halley's "Table of Obſervations," at Breſlaw, which, being the only table of the kind at that time, and making the decrements in the middle ſtages of life nearly equal, ſo far ſupported the truth of the hypotheſis, and juſtified M. De Moivre in adopting it. But in the earlier and later periods of life the decrements are ſo irregular as by no means to accord with this hypotheſis; and ſince ſubſequent tables, more accurately formed, and deduced from more extenſive obſervations, have been publiſhed by Dr. Price, Meſſrs. Wargentin, Suſmilch, and other writers on the ſubject; and the values alſo of ſingle and joint lives for all ages have been computed from them; this hypotheſis is rendered unneceſſary, even in caſes where it is moſt correct: in other caſes, which involve two or three lives in the queſtion, eſpecially if thoſe lives be very young or very old, it gives ſolutions ſo inaccurate as to be altogether unfit for uſe.

By ſuppoſing an uniform decrement in the probabilities of life from infancy to extreme old age, the number of years which a perſon has an equal chance of ſurviving is made to be the ſame with the *expectation* which M. De Moivre by his hypotheſis finds to be equal to half the complement of life; ſo that if the age be four, the expectation will be $\frac{82}{2} = 41$; if the age be 82, the expectation will be $\frac{4}{2} = 2$, while the chance that a child aged 4 ſurvives 41 years is $\frac{41}{82}$, and the chance that a perſon aged 82 ſurvives 2 years is $\frac{2}{4}$. Now ſince each of theſe fractions is $= \frac{1}{2}$, it follows, agreeable to what has been obſerved above, that the one has an equal chance of living 41, and the other of living 2 years, or ſuch a number as ſhall be expreſſed by their reſpective expectations. But by the Breſlaw table the expectations of thoſe lives are ſeverally $40.\frac{2}{3}$ and $3.\frac{1}{2}$ years, while the chance of the younger living $40.\frac{2}{3}$ years is .464, and the chance of the elder living $3.\frac{1}{2}$ years is .53: that is, in the firſt inſtance, the chance is leſs, and in the ſecond greater, than an even one, that the perſon lives ſuch a number of years as ſhall be equal to his expectation. This is true in all other tables deduced from real obſervations, and proves that even in the ſimpleſt caſe the hypotheſis is incorrect.

Mr. Thomas Simpſon, inſtead of ſuppoſing the complement to be the difference between 86 and the age of the given life, aſſumed this complement to be equal to twice the expectation when computed from a table of the real probabilities of life, and by this means leſſened the incorrectneſs of thoſe rules which depended entirely on Mr. De Moivre's hypotheſis. But had this excellent mathematician been poſſeſſed of the preſent tables of obſervation, there is no doubt but that he would have adopted a more genuine method of ſolution. As far as relates to the computation of the probabilities of ſurvivorſhip between any given number of lives, M. De Moivre's hypotheſis in many caſes appears to give approximations which are ſufficiently near the truth; but as the mere determination of ſuch probabilities is of no uſe in computing the values of contingent reverſions, inaſmuch as the diſcount of money muſt be blended in each ſeparate year with the chance of ſurvivorſhip in that year, the inveſtigation of them is a matter of no conſequence, and therefore the hypotheſis of an equal decrement, which often leads to great errors in the doctrine of life annuities, may be wholly laid aſide without injury or inconvenience in any caſe. (See Phil. Tranſactions, vol. 78.)

COMPLEMENT *of a Chord*, in *Muſic*, the note or notes wanting in any chord, to complete its harmony.

COMPLEMENT *of an Interval*, is the minute quantity it wants in particular temperaments.

COMPLEMENT, is the difference or remainder between an octave or eighth, and any given interval, called alſo the inverſion of that interval, (ſee INVERSION); thus, a fifth is the complement or inverſion of a fourth, and a fourth of a fifth; a minor third is the complement or inverſion of a major ſixth, and *vice verſâ*. See THIRD, FOURTH, FIFTH, &c.

COMPLETE, in French *complet*, in *Military Language*, a regiment, troop, or company is ſaid to be complete when it has its full complement of officers, non-commiſſioned officers, and privates, agreeably to the regulations for the time being.

COMPLETUS. *flos*, in *Botany*, a complete flower, furniſhed with both calyx and corolla; *incompletus* being uſed when the latter is deficient, and *nudus* when the former.

COMPLEX, a term ordinarily uſed as ſynonymous with *compound*; though, ſtrictly ſpeaking, there is ſome difference between them.

COMPLEX *object*. See OBJECT.

COMPLEX *oppoſition*. See OPPOSITION.

COMPLEX *term*, or *idea*, is a term or idea compounded of ſeveral ſimple or incomplex ones.

Thus, in the propoſition, *A juſt God cannot leave crimes unpuniſhed*; the ſubject of this propoſition, viz *a juſt God*, is a *complex term*, or ſtands for a *complex idea*, compoſed of two ſimple, or *incomplex* ones, viz. *God* and *Juſt*. Mr. Locke obſerves, that though the mind be perfectly paſſive in the formation of ſimple ideas, yet it exerts ſeveral actions of its own about them, when once formed: and that by this means it is, that they become the materials and foundations out of which all our knowledge is framed.

Theſe acts are chiefly three, *viz.* 1. The combining of ſeveral ſimple ideas into one compound one: and thus it is that all complex ideas are made.

2. The bringing two ideas, whether ſimple or complex, together; ſetting them by each other, and ſo viewing them, without uniting them into one; by which it gets its ideas of relation.

3. The ſeparating ſeveral ideas from all other ideas that accompany them in their real exiſtence: and thus all its general ideas are formed.

As ſimple ideas are obſerved to exiſt in ſeveral combinations united together: ſo the mind may conſider them as united, not only as they are really united in external objects, but as itſelf has joined them: ideas thus made up of ſeveral ſimple ones put together, we call *complex*; as man, beauty, army, gratitude, &c.

Complex ideas, however compounded and decompounded, though their number be infinite, and their variety endleſs, may be all reduced under theſe three heads, viz. *modes*, *ſubſtances*, and *relations*; which ſee under their proper heads, MODE, SUBSTANCE, and RELATION. Complex ideas are often conſidered as ſingle and diſtinct beings, though made up of ſeveral ſimple ideas; as body, ſpirit, &c. See COMPOSITION of *ideas*.

COMPLEX *propoſition*, in *Logic*, is that in which the ſubject, or predicate, or both, are made up of *complex* terms: and if the term added to the ſubject be eſſential or neceſſary to it, then it is called *explicative*; otherwiſe it is *determinative*, the adjoined term limiting the ſubject to a particular part of its extenſion. Some logical writers aſcribe the complexion of a propoſition, in ſome caſes, to the copula, as in modal propoſitions; but this rather pertains to the predicate. See *Compound* and *Modal* PROPOSITION.

COMPLEX *ſyllogiſm*, is that in which the middle term is not connected with the whole ſubject, or the whole predicate in two diſtinct propoſitions, but is intermingled and compared with them by parts: *e. g.* The ſun is a ſenſeleſs being, the Perſians worſhipped the ſun, therefore the Perſians worſhipped a ſenſeleſs being.

COMPLEXI *Pars*, in *Anatomy*, a name given by Riolanus, and others, to a muſcle called by Albinus *Biventer cervicis*, and by ſome the *complexus*.

COMPLEXIO, COMPLEXION, in *Metaphyſics*, the union, or coalition of ſeveral things different from each other; either really, or only in our conception. See COMPLEX.

COMPLEXIO, in *Logic*, is ſometimes applied to the ſecond operation of the mind, *viz.* the judgment; conſidered as it affirms or denies any thing; ſuch affirmation, &c. neceſſarily importing a combination of ſeveral things.

Complexio is ſometimes alſo uſed by logicians in the ſenſe of dilemma.

COMPLEXIO, [illegible] both beginning, and ending, with the ſame word.

Thus Tully: "Quis legem tulit?" Rullus. "Quis majorem partem populi ſuffragiis privavit?" Rullus. "Quis comitiis præfuit?" Rullus.

COMPLEXION, in *Phyſics*, is uſed for the temperature, habitude, or natural diſpoſition of the body.

Some philoſophers diſtinguiſh four general and principal *complexions* in man, *viz.* the *ſanguine complexion*, which, according to them, anſwers to the air; having the qualities thereof, as being hot and moiſt. It takes its name from *ſanguis*; becauſe the blood is there ſuppoſed to be predominant.

The *phlegmatic complexion* takes its name from the pituita, or phlegm, in which it abounds; and correſponds to water; being cold and moiſt.

The *bilious*, or *choleric complexion*, takes its name from the bile, or choler: it is ſuppoſed of the nature of fire, hot and dry.

Laſtly, the *melancholic complexion* partakes of the nature of earth, being cold and dry; but this ſort of reaſoning is now not much regarded.

Under this article we may introduce a ſubject that has occaſioned much diſcuſſion, and conſiderable difference of opinion among phyſiologiſts. It relates to the variety of complexion or of colour that has ſubſiſted amongſt the inhabitants of different nations. Some perſons, diſſatisfied with the ſeveral hypotheſes that have been ſuggeſted for explaining this phenomenon, have been led to conceive that there is a ſpecific difference in the human race, and that the variations of colour are owing to their not having ſprung from one common original. But this hypotheſis contradicts the moſt ancient and authentic hiſtory extant, which repreſents Adam and Eve as the progenitors of all mankind; and it is alſo liable to various other objections which we ſhall take occaſion diſtinctly to ſpecify in the courſe of this work. Dr. Hunter, who has publiſhed a theſis on this ſubject, has inveſtigated it with peculiar attention; and he gives it as his decided opinion, that there is no ſpecific difference among mankind. In order to guard againſt the confuſion which has ariſen from the uſe of the term "ſpecies," he begins with defining it, and he comprehends under the ſame ſpecies all thoſe animals which produce iſſue capable of propagating others reſembling the original ſtock, from which they ſprung. According to this ſenſe of the term, he conſiders the whole human race as belonging to the ſame ſpecies. But, as in the vegetable creation, one ſpecies of plants includes ſeveral varieties depending upon climate, ſoil, culture, and ſimilar circumſtances that are incidental, the caſe is the ſame with reſpect to the human race; the varieties that occur pertain to the ſame ſpecies, and are produced by the operation of natural cauſes. Of the different colours that ſubſiſt among mankind, he enumerates the following, *viz.*

- *Black*, comprehending
  - Africans under the Line.
  - Inhabitants of New Guinea.
  - Inhabitants of New Holland.
- *Swarthy*, including
  - The Moors in the northern parts of Africa.
  - The Hottentots in its ſouthern parts.
- *Copper-coloured*, as the Eaſt Indians.
- *Red-coloured*, as the Americans.
- *Brown-coloured*, to which claſs belong
  - Tartars.
  - Perſians.
  - Arabs.
- *Brown coloured*, comprehending
  - Africans on the coaſt of the Mediterranean.
  - Chineſe.
- *Browniſh*, including
  - The inhabitants of the ſouthern parts of Europe; as,
    - Sicilians,
    - Abyſſinians,
    - Spaniards,
    - Turks, and alſo the Samoiedes and Laplanders.
- *White*, to which belong
  - Moſt of the European nations; as,
    - Swedes, Danes, Engliſh, Germans,
    - Poles, &c. Kabardinſki, Georgians, and.
  - Inhabitants of the iſlands in the Pacific Ocean.

In tracing the cauſes of theſe differences of colour, he ſets out with obſerving that its ſeat is unqueſtionably in the ſkin; that it is confined to the cuticle, conſiſting of the epidermis and reticulum; and that it chiefly occupies the latter of theſe. The cuticle, he obſerves, is much thicker and harder in black than in white people; the reticulum in the latter being a thin mucus, in the former a thick membrane. The ſeat of colour in whites he conceives to be tranſparent, and either totally deprived of veſſels, or furniſhed with a very ſmall number; as the yellow colour appearing in the jaundice vaniſhes when the cauſe of the diſeaſe is removed, which is not the caſe with ſtains in the cuticle from gun-powder, or ſimilar cauſes. He then mentions three cauſes which contribute to deſtroy the pellucidity of the cuticle, to give it a brown colour, and to thicken it; *viz.* acceſs of air, naſtineſs, and the heat of the ſun: the effect of theſe he illuſtrates by examples; but he apprehends the laſt to be the moſt powerful. Admitting ſuch influence of theſe cauſes, he ſuppoſes that it is ſufficient to account for all the diverſities of colour, that are obſervable among mankind. He proceeds to obſerve, that all the inhabitants of the torrid zone incline more or leſs to a black colour; and the difference that is perceivable among them may be owing, not to mere heat, but to the other cauſes alſo; and if we conſider that even in the torrid zone there is a conſiderable difference of temperature, the exiſtence of a white nation in this climate would not deſtroy the argument. He is farther of opinion, that the exiſtence of a brown colour, and of conſiderable varieties from white, in the northern and coldeſt parts of Europe, may be very eaſily explained, by adverting to the manner of life of the inhabitants, who of courſe are either expoſed to the inclemency of the air, or to the conſtant naſtineſs of ſmoky houſes. If, to this reaſoning, it ſhould be objected, that infants are ſubject to theſe differences even when they are born, and previouſly to the influence of the cauſes above-mentioned, Dr. Hunter replies, that many peculiarities acquired by parents are tranſmitted to their poſterity; in proof of which, he refers to hereditary diſeaſes, which will continue to affect families for many generations. Thus, a parent expoſed to cauſes that deſtroy the natural whiteneſs of his complexion, will beget ſwarthy children; and the ſame cauſes continuing to operate upon the ſon, the blackneſs will be increaſed. In this manner, all the different ſhades may have been at firſt induced, and afterwards continued. To this objection, however, it might be anſwered, that the fact is not admiſſible; as it is now generally allowed, that the children of the blackeſt negroes are born white.

Mr. Clarkſon, in a diſſertation introduced in his "Eſſay on the Commerce and Slavery of the Human Species," has conſidered and well illuſtrated the ſubject of complexion. In the inveſtigation of this ſubject, the firſt queſtion that occurs relates to the preciſe ſeat of the colour. As the old anatomiſts commonly divided the ſkin into two parts or laminæ, *viz.* the cuticle and cutis or true ſkin, they muſt have ſuppoſed, that as the latter is the ſame in all the varieties of mankind, however different their external hue, the ſeat of colour muſt have exiſted in the cuticle or upper ſurface. Malpighi, however, diſcovered that the ſkin is divided into three laminæ; *viz.* the cuticle, the true ſkin, and a kind of coagulated ſubſtance ſituated between both, which he denominated the "rete mucoſum." Accordingly, this diſcovery ſerved to aſcertain the point in queſtion; for it afterwards appeared, that the cuticle, ſeparated from the other laminæ, was ſemi-tranſparent; and that the cuticle of the blackeſt negro was of the ſame tranſparency and colour with that of the pureſt white; and as the true ſkins of both were invariably the ſame, the rete mucoſum muſt be the ſeat of colour. That this is the fact has been alſo determined by a variety of anatomical experiments and phyſiological obſervations. The cauſes, therefore, that operate in producing difference of colour, muſt effect it by acting on the rete mucoſum, which, from the numberleſs perforations of the cuticle, is no leſs acceſſible than the cuticle itſelf. Theſe cauſes are probably thoſe various qualities of things, which, combined with the influence of the ſun, contribute to form what is called "climate." Moreover, it is a farther confirmation of this hypotheſis, that the mucous ſubſtance before-mentioned is ſubject to variation, according to the difference of climates from the equator to the poles. Thus, the inhabitants of many kingdoms and iſlands of Aſia are found to have their rete mucoſum black; thoſe of Africa, ſituated near the line, are of the ſame colour; thoſe of the maritime parts of the ſame continent, are of a duſky brown, nearly approaching to it; and the colour becomes lighter or darker, in proportion as the diſtance from the equator is either greater or leſs. The Europeans are the faireſt inhabitants of the world: thoſe ſituated in the moſt ſouthern regions of Europe, have in their rete mucoſum a tinge of the dark hue of their African neighbours. Admitting theſe facts, we are led to conclude, that climate has a very conſiderable influence in occaſioning a difference of colour. It has, however, been objected to this reaſoning, that people of the ſame climate, geographically conſidered, or under the ſame parallels, are not exactly of the ſame colour. But to this objection it has been replied, that climate, phyſically conſidered, depends upon a variety of accidental circumſtances. See Climate. It ſhould alſo be conſidered, that, although the inhabitants of the ſame parallel are not exactly of the ſame hue, yet they differ only by certain ſhades of the ſame colour; and, therefore, if climate has really an influence on the mucous ſubſtance of the body, we muſt expect to find not only a gradation of colour in the inhabitants from the equator to the poles, but alſo different ſhades of the ſame colour in the inhabitants of the ſame parallel. We might alſo add another argument of great weight, *viz.* that when the black inhabitants of Africa are tranſplanted to colder, or the white inhabitants of Europe to hotter climates, their children, born there reſpectively, are of a different colour from themſelves, that is, lighter in the firſt, and darker in the ſecond caſe. To this purpoſe the abbé Raynal obſerves, that the children, which the Africans procreate in America, are not ſo black as their parents were; and that after each generation, the difference becomes more palpable. It is poſſible, he adds, that after a numerous ſucceſſion of generations, the men come from Africa would not be diſtinguiſhed from thoſe of the country into which they have been tranſplanted. If we admit the fact above ſtated, that climate has an influence on the mucous ſubſtance, we may reaſonably imagine that this variation of the colour of children from that of their parents muſt take place; for being born white, and not being ſubject to the influence of cauſes equally powerful in colder climates, with thoſe to which their parents were ſubject in the hotter climates from which they were removed, it muſt follow that the ſame effect cannot poſſibly be produced.

On the other hand, we may here allege an important fact, ſtated by Dr. Mitchell (Phil. Tranſ. N° 476. § 4.). "The Spaniards," he ſays, "who have inhabited America, under the torrid zone for any time, are become as dark-coloured as our native Indians of Virginia, of which I myſelf have been a witneſs; and were they not to intermarry with Europeans, but lead the ſame rude and barbarous lives with the Indians, it is very probable that, in a proceſſion of many generations, they would become as dark in complexion." Another writer, deſcribing the European ſettlements on the African coaſt, obſerves, that "there are ſeveral other ſmall Portugueſe ſettlements, and one of ſome note at Mitomba, a river in Sierra Leone; the people here called "Portugueſe" are principally perſons bred from a mixture of the firſt Portugueſe diſcoverers with the natives, and now become, in their complexion and woolly quality of their hair, perfect negroes, retaining, however, a ſmattering of the Portugueſe language."

Another circumſtance might alſo be mentioned by way of corroborating the argument before us; and this is, that the members of the ſame family, ſeparated from each other, and migrating into different countries, have not only changed their family complexion, but have aſſumed as many different colours as the different regions of the globe in which they have ſettled. The Jews furniſh a remarkable inſtance to this purpoſe. Theſe people, though ſcattered over the face of the earth, preſerve themſelves a diſtinct people, and never intermarry with any out of their own body, ſo as to have any mixture of blood in their veins, by which they ſhould differ from each other; and yet it is an undoubted fact, that the Engliſh Jew is white, the Portugueſe ſwarthy, the Armenian olive, and the Arabian copper-coloured; and there appear to be as many different ſpecies of Jews as countries in which they reſide. It appears further from the teſtimony of the moſt ancient hiſtorians, that the darkeſt black complexion has actually changed in a ſucceſſion of years into the pureſt white. Herodotus informs us, that the Colchi were black and that they had criſped hair. Theſe people were a detachment of the Ethiopian army under Seſoſtris, who followed him in his expedition, and ſettled in that part of the world where Colchis is ſaid to have been ſituated. Their deſcendants probably remained in the ſame country. If this be the caſe, they muſt have totally changed their complexion; or the black inhabitants of Colchis muſt have acquired the hue of the fair Circaſſian. If indeed they migrated in any one direction from Colchis and to any diſtance within 1000 miles of Colchis, ſtill they muſt have changed their colour; for if they had gone in an eaſtern or weſtern direction, their colour muſt have been the ſame as that of the Circaſſians; if to the north, whiter; if to the ſouth, of a copper colour. Within the above aſſigned diſtance of Colchis, there are no black people.

Profeſſor Zimmermann of Brunſwick, in his work entitled "The Geographical Hiſtory of Man, &c," has ſatiſfactorily proved, that the complexion of the human ſpecies uniformly correſponds to the degree of heat or cold to which they are habitually expoſed. In eſtabliſhing this poſition, he diſtinguiſhes between climate, conſidered geographically and phyſically, and thus furniſhes an anſwer to the erroneous reaſoning of Lord Kames on this ſubject. At Senegal, and in places adjacent, the thermometer is often at 112 or 117 degrees in the ſhade; and here we find the inhabitants jet-black with woolly hair. The heat is equally great in Congo and Loango, and theſe countries are inhabited by negroes only; whereas in Morocco to the north of theſe regions, and at the Cape of Good Hope, to the ſouth, the heat is not ſo intenſe, nor are the inhabitants of ſo deep a hue. Lord Kames aſks, why are not the Abyſſinians and the inhabitants of Zaara of as dark a complexion as the Moors on the coaſt of Guinea; Zimmermann replies that theſe countries are much cooler. The deſert is not only further from the equator, but the winds blowing over the Atlas mountains, which, like the Alps, are covered with ſnow, and the weſterly wind coming from the ſea, very much mitigate the heat. Nor is Abyſſinia ſo warm, as either Monomotapa or Guinea. The N. E. winds from the ſide of Perſia and Arabia are cooled by their paſſage over the Red ſea; the northern winds of Egypt loſe much of their heat on the chain of mountains that is extended between the countries; the winds from the ſouth and the weſt are ſea winds. Thus the only quarter from which they can derive exceſſive heat is from the weſt, as the air on this ſide muſt paſs over tracts of heated lands. For a ſimilar reaſon negroes are not found either in Aſia or South America, under the equator. Theſe countries, as M. Zimmermann obſerves, being expoſed, from their ſituation, to ſea-breezes and cooling winds from the continent. He alſo obſerves, in confirmation of this hypotheſis, that the mountaineers in warm climates, as in Barbary and Ceylon, are much fairer than the inhabitants of the vallies; that the Saracens and Moors, who conquered the N.E. part of Africa in 1700, from being brown, are become like the negroes near the equator; that the Portugueſe, who ſettled at Senegal in 1400, became blacks; and it is aſſerted by Tudela the Jew, that his countrymen in Abyſſinia acquired the dark complexion of the conquered nations.

Upon the whole it may be obſerved, that colour is a kind of habit of the body, which is gradually acquired, and after a ſucceſſion of ages, fixed and rendered permanent. Thus, the ſanguine countenance will be perpetual in the higheſt latitudes of the temperate zone, and, as we deſcend to the ſouth, we ſhall find the ſwarthy, the olive, the tawny, and the black. The uniformity of the effect in the ſame climate, and on men in a ſimilar ſtate of ſociety, proves the efficacy and the certainty of the cauſe. As mankind are for ever changing their habitations by conqueſt or commerce, we find that, in all climates, they cannot endure the change, but are ſo aſſimilated by time, that we cannot ſay with certainty, whoſe anceſtor was the native of the clime, and whoſe progenitor was the intruding foreigner. For a further illuſtration and confirmation of the general arguments comprehended in this article, we refer to an "Eſſay on the Cauſes of the Variety of Complexion and Figure in the Human Species" by Dr. Smith, profeſſor of moral philoſophy in the college of New Jerſey. See NEGROE.

COMPLEXUS MUSCULUS, in *Anatomy*, derives its name from the intermixture of tendon with its muſcular fibres, which gives to its ſurface a confuſed appearance. It ariſes from the tranſverſe proceſſes of five, ſix, or ſeven of the upper dorſal vertebræ, by ſo many diſtinct ſlips; from the tranſverſe proceſs of the laſt cervical vertebra; and from the oblique or articulating proceſſes of the ſixth, fifth, and fourth vertebræ of the neck. The faſciculi of fibres from theſe numerous points of origin meet together to form a broad, flat, and ſtrong muſcle, which is implanted into the occipital bone, occupying the hollow in front of the external tranſverſe ridge of the bone. It ſometimes receives a ſmall fleſhy portion from the ſpinous proceſſes of one or two of the upper dorſal vertebræ; and is generally connected in ſome degree with the longiſſimus dorſi ſacrolumbalis and tranſverſalis colli. That portion of the muſcle, which is towards the ſpines of the vertebræ, is divided into two fleſhy portions by an intermediate tendon, and is ſeparate from the reſt at its origin; this is deſcribed by Albinus, Soemmerring, and others, as a diſtinct muſcle, by the name of biventer cervicis: we follow Cowper, Douglas, and Winſlow, in conſidering this as a part of the complexus, ſince it is always connected to the reſt of the muſcle, for two or three inches before its inſertion.

The action of the complexus conſiſts in carrying the head backwards upon the atlas; and in reſtoring it to the erect poſition, when it has been bent forwards. Its longeſt fibres will alſo have the ſame effect on the neck, *viz.* that of ſtraightening and carrying it backwards.

COMPLEXUS, *Minor*, is a name given by Winſlow, to the trachelo-maſtoideus muſcle, which ſee.

COMPLICATION *of diſeaſes*, a mixture, or combination of ſeveral diſeaſes; eſpecially where they have any affinity to one another; as the dropſy, aſthma, and jaundice, happening together.

What much perplexes the phyſicians is, when with a fever there is a complication of ſome other diſorder.

COMPLINE, in *Eccleſiaſtical Antiquity*, denotes that even-ſong, which completed the whole ſervice of the day in religious houſes, and began at nine of the clock at night.

COMPLUTENSIAN BIBLE. See *Greek* BIBLES, and POLYGLOTT. The Complutenſian edition of the Bible, which the reader will find deſcribed and particularly noticed, under the articles to which we have referred, has been highly extolled by Mill and Goeze, and as much depreciated by Wetſtein and Semler. Michaelis, in the ſecond edition of his "Introduction," &c. endeavoured to ſteer a middle courſe between the oppoſite opinions of Mill and Wetſtein; though he believed, on the authority of the latter, that the editors, actuated by religious zeal, had materially altered the Greek text from the Vulgate. But Goeze, he ſays, in his "Defence of the Complutenſian Bible," printed at Hamburgh, in 1765, has enabled him to form a proper judgment of that work; and he acknowledges, that he had too cloſely adhered to the opinion of Wetſtein, after the peruſal of the following publications by the ſame author, *viz.* "Complete Defence of the Complutenſian Greek Teſtament, with a Collection of the principal Differences between the Greek Text, and the Latin Text of that Edition," printed in 1766, and the "Continuation of the Defence of the Complutenſian Greek Teſtament, &c." publiſhed in 1769. Michaelis, having ſince had acceſs to the Complutenſian bible in the univerſity library of Gottingen, has been enabled to ſpeak of it with greater certainty. He has particularly uſed it in the Greek verſion of Geneſis, the Proverbs of Solomon, and the firſt book of the Maccabees; and in theſe books he has found its reading as pure, and as little altered from the Latin, as Goeze had deſcribed them. It has been queſtioned what were the MSS. from which this edition was prepared, and whether the editors had any beſides thoſe which were ſent to them from Rome; the ſilence of the editors is no proof of the contrary, for they make no mention of the Codex Rhodienſis, which had been preſented to Cardinal Ximenes, though Stunica, in his controverſy with Eraſmus, frequently applies to it, as a MS. uſed in the Complutenſian edition; and the Codex Beſſarionis, which was uſed in the Septuagint, had been preſented to him, by the ſenate of Venice. Moreover, as the New Teſtament was begun in 1502, it is wholly incredible that they ſhould have had no other MSS. than thoſe ſent from Rome, becauſe Leo X. who communicated theſe MSS. was not pope before the year 1513, and the ſubſcription at the end of the Revelation bears date January 10, 1514. If, therefore, the MSS. were ſent by Leo X., they muſt have arrived when at leaſt three parts of the Greek Teſtament were already printed, and yet the editors, at leaſt in the preface, mention no other MSS. One mode, ſays Marſh, in his notes on Michaelis's tranſlation, of ſolving this difficulty is, to ſuppoſe that MSS. were ſent from Rome by Julius II. the predeceſſor of Leo X., and that the writer of the preface to the Complutenſian Greek Teſtament, who knew that the latter was at that time pope, but, perhaps, was ignorant how long he had reigned, committed an anachroniſm in aſcribing to Leo X. what had been done by Julius II. Or, perhaps, he knew that they were ſent by Julius II.; but meant to flatter the vanity of the reigning pope, by attributing to him the act of his predeceſſor. Or, Leo X. might, before he was pope, have been inſtrumental in procuring them from the Vatican, and be therefore entitled to the compliment. However this be, it ſeems probable, that the editors, beſides the Codex Rhodienſis, had other MSS. of the Greek Teſtament, which had been procured by the cardinal. But whether they were ancient or modern, of great or little value, it is difficult to determine, as the editors have given no account of them. Wetſtein thinks they were modern, becauſe the readings of the Complutenſian bible have a remarkable agreement with thoſe of the MSS. written in the 14th, 15th, and 16th centuries; and this opinion is confirmed by the ſhape of the types, for they are ſuch as we find in the moſt modern MSS; and it is probable that the editors had their types caſt in imitation of the MSS., which they employed on the occaſion. Michaelis, however, in this account of the types, is not quite accurate; for of all the ſpecimens of Greek hand-writing, which Montfaucon has given in his "Palæographia Græca," from the firſt introduction of the ſmall letters down to the 15th century, none reſemble the types of the Complutenſian edition more than that which is found in MSS. of the 9th century. On the other hand, letters not very unlike the Complutenſian are found in MSS. of the 11th, 12th, and even 13th centuries. Moreover, as no MS. written in ſuch letters, as are uſed for the Complutenſian edition, is without accents, and the editors appeal not to the MSS. which they actually uſed but to the poems of Callimachus, and the Sibylline prophecies, there is reaſon to ſuſpect, that their MSS. had accents, and conſequently were modern. Accents, however, if it be allowed that the Complutenſian edition had them, though it has been generally ſaid (not juſtly) that it is printed without them, afford no proof that a MS. is modern; for they are found in ſeveral very ancient MSS. written even with uncial letters, as the Vaticanus, Claromontanus, &c. &c. and perhaps, ſays Mr. Marſh, there are as many ancient MSS. with uncial letters, which have accents as thoſe which have not.

With regard to the main queſtion, whether the MSS. uſed by the Complutenſian editors were ancient and valuable, Mr. Marſh candidly acknowledges that he is too little acquainted with the Complutenſian bible to be able to form any judgment; and he therefore contents himſelf with obſerving, that Grieſbach accedes to the opinion of Wetſtein and Semler, and ſays, in the preface to the ſecond volume of his Greek Teſtament (p. 16); "Complutenſes non habuerunt codices Græcos, niſi paucos, recentes, exigui fere, ſi ad lectionum bonitatem ſpectes, pretii."

It has been ſuggeſted, that the Complutenſian editors, in conſequence of a too high opinion of the Vulgate, and a miſtaken zeal for the Chriſtian religion, have ſometimes introduced into the Greek text readings of the Vulgate, which they did not find in the Greek MSS.

The Greek text of the diſputed paſſage, 1 John, v. 7., in the Complutenſian edition, ſeems to have been a mere tranſlation of one of the editors; becauſe the paſſage is found in not a ſingle ancient, and in only two modern MSS. the Montfortianus and the Ravianus, the latter of which is only a copy of this edition; and in the former, the text is very different from that in the Complutenſian edition. It cannot, therefore, as in the third edition of Eraſmus, have been taken from this MS.: though, on the other hand, it is not impoſſible that they found it in ſome modern MS., in which the paſſage, as in the codex Montfortianus, had been already tranſlated. The queſtion can never be decided, becauſe the MSS. which they uſed are either deſtroyed, or are at leaſt unknown. For an account of the fate of theſe MSS., ſee the article Alcala. Michaelis candidly explains the conduct of the Complutenſian editors ſo as to remove the charge of diſhoneſty. They might believe, he ſays, that this paſſage was really genuine, and, on account of its ſuppoſed importance, take no notice of its alteration from the Greek MSS.; in the ſame manner as the verſe has been inſerted by later editors in Luther's verſion. Or, they might have made ſome remarks on it, which were afterwards eraſed by the cenſors of this edition; for, contrary to their uſual cuſtom, they have a marginal note on 1 John, v. 7., which is in itſelf unimportant, and almoſt implies that ſomething originally preceded. If they have taken the paſſage from a modern MS., they have only acted like Eraſmus, who has inſerted it on the authority of a very modern MS. which he had never ſeen. In ſhort, many of the beſt editors have been guided in this paſſage by a miſtaken zeal for the Chriſtian religion, and have acted on principles which they have never admitted in other places. It was the principal object of Goeze to ſupport the authenticity of this paſſage, and as it occurs in the Complutenſian bible, he defended the antiquity and value of the Greek MS. from which he ſuppoſed that paſſage had been taken. On the other hand, Semler's object was to ſhew the ſpurioufneſs of this paſſage, and at the ſame time to ſupport the opinion of Wetſtein, that the text of the Complutenſian Greek Teſtament, in general, is of little value. The genuineneſs of this paſſage is now generally exploded by the moſt approved biblical critics.

The Complutenſian edition is extremely ſcarce, becauſe only 600 impreſſions were taken off, and is become too expenſive for a private library. That which is now at Gottingen coſt 480 florins, and the late Münchauſen gave an order to his commiſſioner as far as 900; and the price of it, ſays Michaelis, will ſtill increaſe, in proportion as its great excellence, eſpecially in the Septuagint, ſhall be better known. Mill, Bengelius, and Wetſtein, have collated this edition as a MS. with great diligence; but their extracts are by no means complete. Goeze has alſo given extracts from it, in his "Complete Defence of the Complutenſian edition," (p. 277), which, in the proper ſenſe of the word, may be called critical, and which no future editor of the Greek Teſtament ought to leave unnoticed. Michaelis thinks, that a real ſervice would be rendered to thoſe who are engaged in ſacred criticiſm, if a new edition both of the Greek and Latin Teſtament was publiſhed, that was an exact copy of the Complutenſian. From the Greek text of the Complutenſian edition were printed the following, *viz.* ſeven at Antwerp in 1564, 1573, 1574, 1590, 1591, 1601, 1602; five Geneva editions in 1609, 1619, 1620, 1628, 1632; and, laſtly, that of Mayntz, in 1753. Theſe are all deſcribed in Le Long Bibl. Sacra, ed. Maſch. P. i. p. 191—195. See Polyglott.

COMPLUTICA, in *Ancient Geography*, a town of Spain in the Tarragonenſis, placed by Ptolemy in the country of the Callaici, and thought to be the preſent village of Compludo, in Galicia. It is marked in the chart of M. d'Anville on the right of the Durius, to the ſouth-weſt of Pallantia.

COMPLUTUM, a town of Spain, in the Tarragonenſis, placed by Ptolemy in the country of the Carpetani, and marked in the chart of M. d'Anville in Hiſpania citerior, N.E. of Mantua; now *Alcala de Henares*, which ſee.

COMPOLI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Lavora; 4 miles E. of Sora.

COMPONE', or *Gobony*, in *Heraldry*, is compoſed of two colours in equal diviſions in a border, or any other ordinary; if it conſiſts of two ranges it is called counter-compony, and if of three, it is then termed chequé, and is generally uſed in a border to denote illegitimacy.

COMPOS *Mentis*. See Non-Compos.

COMPOSED *Baſtion*. See Bastion.

COMPOSER *of Muſic*, a perſon who invents a melody, and cloaths it with harmony, according to the eſtabliſhed rules of the art. Under the word *compoſition* we ſhall detail the qualifications requiſite to ſupport this character. Yet theſe are inſufficient to form a complete compoſer, whoſe productions will be felt and admired whenever they are heard. All the ſcience poſſible, without the inſpirations of genius, is unable to command attention, and intereſt an audience, at all times, and in all places. They are only gifted men that poſſeſs ſuch powers. What is meant here by genius, is not a whimſical and capricious imagination, that quits a flowery road to ramble in thickets, through briars and brambles; that to render harmony piquant, loads it with diſcords; and inſtead of grace and elegance, is labouring to ſurpriſe by extraneous modulation, and to divide the whole ſcale into half notes; true genius is that latent fire which inflames the compoſer, irreſiſtibly forces him to write, and inceſſantly ſupplies him with new melodies, always agreeable, expreſſive, and natural, accompanied by a harmony pure, touching, and majeſtic, which embelliſhes melody, without overpowering it. "This was the guide" ſays the Citizen of Geneva, "that led Corelli, Vinci, Perez, Jomelli,

melli, and Durante, to the ſanctuary of harmony; and Leo, Pergoleſi, Haſſe and Buranello, to that of good taſte." We have to add to theſe, Handel, whoſe ſublime works were never heard by Rouſſeau; the elder Stamitz, Piccini, Sacchini, Cimarosa, and Paeſiello, with Haydn and Mozart, who have gone ſomewhat further in vocal muſic, and many leagues in inſtrumental,.

The knowledge of harmony is doubtleſs the foundation of compoſition. To fill the chords, prepare and reſolve diſcords, find the fundamental baſe, and know all the other little elementary rules, is neceſſary; but with the rules of harmony alone, we are not nearer being compoſers, than being orators by knowing the rules of grammar. Padre Martini ſays, that no one can be a good compoſer without ſinging in good taſte, and playing well upon the organ. His rules are for a real *maeſtro di capella*, an eccleſiaſtical compoſer; but for ſecular muſic he would have ſaid it was neceſſary to ſing and play well on the harpſichord or piano forte. In ſetting words for the ſtage, he ought to know what paſſages are difficult, and what eaſy to execute; what ſtyle ſuits the ſinger, and what the character he has to repreſent; he is to know the compaſs of voices and inſtruments, and their peculiar genius and powers; how to produce effects, and when to apply them; to feel the character of different meaſures; to know all the difficulties and pedantry of the art: imitations, fugues, canons, double counterpoint, and how to write for double, triple, and quadruple choirs. To theſe add the myſterious laws of modulation; and all this is no more than preparatory to compoſition. But he muſt inherently poſſeſs a fund of beautiful melodies, ſublime harmony, and grand deſigns.

Beſides correct harmony, correct expreſſion, in lyric compoſitions, is required. The ſpirit of three ſeveral kinds of compoſition muſt be called up in writing for the church, the ſtage, and the chamber. In the firſt, ſolemnity and harmony muſt be invoked; in the ſecond, a diſtinct ſtyle for each character, ſtrongly marked by the poet; ingenious and ſpirited ſymphonies, picture ſque accompaniments, a judicious mixture of inſtruments, and their peculiar powers, occaſionally called forth; and for the third ſpecies of compoſition, pieces that require but few hands and few voices; free from all tremendous difficulties, in want of no wind inſtruments; and, unleſs catches and glees are in queſtion, no proviſion need be made for more than one or two voices, and a quartet band. *La muſica di camera*, chamber muſic, requires eaſe, grace, and elegance, more than force, energy, and feats of execution.

Among the various ſtyles of compoſition for which an accompliſhed maſter ſhould be prepared, is the military, in which wind-inſtruments and drums are chiefly employed. To know the compaſs, ſcale, genius, and defects, of the trumpet, horn, clarinet, hautbois and baſſoon, both in the orcheſtra and the field, will require ſome ſtudy, counſel and experience.

Rouſſeau ſeems ſometimes to regard muſicians as mere inſtruments, incapable of reflexion; and that it is the buſineſs of philoſophers to think for them; ſo imagine M. Suard, and all ſpeculative muſicians; but in the following advice to a compoſer, Jean Jaques ſeems to require more meditation and reflexion than the dæmon of compoſition, by which a man of genius is poſſeſſed, will allow; who, abſorbed in his own ideas, or impelled by the ideas of others, flies to his pen or his inſtrument, without metaphyſical reaſoning, or analytical inquiry into the foundation of his art. But Rouſſeau ſums up the article *Compoſer (Compoſiteur)*, in his Dictionary, with the following inſtruction. "In compoſing, the author has to conſider the phyſical production of ſound, and that its ſole uſe is to delight the ear; or if he mounts up to imitative muſic, he has to move the paſſions by moral effects. In the firſt inſtance, he has to ſelect the moſt pleaſing ſeries of ſound, and agreeable harmony; but in the ſecond, he ought to conſider muſic with reſpect to its ſimilarity with the inflexions of the human voice in ſpeech, and the poſſible conformity between the harmonical combinations of ſound and imitable objects." This is all very fine and profound: but we apprehend, that the moſt happy effuſions of genius have been generated without ſpeculative aſſiſtance.

For the mechanical rules by which a compoſer is to ſteer, we ſhall refer our readers to the article COUNTERPOINT; where, though its principal rules are diſperſed through the work, we ſhall collect and form them into a ſynopſis, and illuſtrate precepts by examples.

In this muſical grammar, we ſhall perplex the ſtudent with no mathematical calculations, no ratios, harmonics, or ſpeculations on the philoſophy of ſound; but adhere cloſely to practical knowledge of immediate uſe in the firſt ſtages of ſtudy. We ſhall not even attempt to give new melodies, or harmonical combinations; but endeavour to indicate the foundation on which the beſt models of compoſition have hitherto been built. See COUNTERPOINT, CONCORDS, DISCORDS, HARMONY, and MODULATION.

COMPOSITÆ, or COMPOSITI, in *Botany*, the twenty-firſt natural order in the Philoſophia Botanica of Linnæus; and the forty-ninth in the Prælections, publiſhed after his death by Giſeke. The plants with compound flowers are kept diſtinct by moſt authors, with only a little difference as to the proper limits and moſt convenient diviſions of the order. But Linnæus obſerves, that, though it is perfectly natural, its eſſential character is not eaſily determined. A compound flower, from the obvious meaning of the term, implies the union of ſeveral flowers, or florets, as in this caſe they are uſually called, by ſome common band. But this character is not peculiar to the compoſite plants, nor does it extend to all their genera. For cephalanthus, dipſacus, ſcabioſa, &c. have ſeveral florets included in a common calyx, but belong to a different family; and ſeriphium, corymbium, and ſtrumpfia, have only one flower in each calyx, and yet cannot be ſeparated from thoſe which are truly compound. Nor will the united anthers, which Linnæus has taken for the diſtinguiſhing character of his artificial claſs ſyngeneſia, exactly apply to this natural order; jaſione, viola, impatiens, &c. have ſuch anthers, but cannot properly be arranged with the compoſitæ.

In the Philoſophia Botanica the order ſtands thus:

I. *Semifloſculoſi*, prenanthes, lactuca, chondrilla, hieracium, crepis, andryala, hypochæris, picris, hyoſeris, leontodon, ſcorzonera, tragopogon, ſcolymus, ſonchus, lapſana, cichorium, catananche, elephantopus. II. *Capitati*, echinops, ſphæranthus, gundelia, arctium, ſerratula, onopordum, carduus, cynara, carthamus, carlina, cnicus, atractylis, centaurea, corymbium. III. *Corymbiferæ*, ſtoebe, ſantolina, chryſocoma, tanacetum, kleinia, ſtoehelina, xeranthemum, gnaphalium, carpeſium, conyza, tarchonanthus, baccharis, erigeron, tuſſilago, doronicum, ſolidago, ſenecio, inula, aſter, gerbera, othonna, chryſanthemum, matricaria, buphthalmum, anacyclus, cotula, anthemis, achillea, eriocephalus, helenium, arctotis, bellis, tagetes. IV. Helianthus, rudbeckia, coreopſis, bidens, verbeſina, ſigeſbeckia, milleria, ſilphium, eupatorium, ageratum, oſteoſpermum, calendula? chryſogonum? melampodium? tridax? tetragonotheca?

All theſe are retained in the Prælections, except gerbera, which has been aboliſhed, and its ſpecies referred to arnica. Several of them are alſo placed in different diviſions.

The following is the arrangement in the ſynoptic table annexed to the Prælections. Thoſe printed in Italics were added by Linnæus himſelf; and thoſe marked with aſteriſks are additions by Giſeke.

I. *Capitatæ*, gundelia, echinops, ſphæranthus, arctium, ſerratula, carduus, cnicus, onopordum, cynara, carlina, *gorteria*, atractylis, carthamus, centaurea, *zoegea*, elephantopus, removed from ſemifloſculi, *barnadeſia*, *vernonia, *Schreb.* *liatris, *Gært.* II. *Semifloſculoſæ*, ſcolymus, cichorium, catananche, lapſana, hypochæris, *ſeriola*, *krigia, *Schreb.*, hyoſeris, *rothia, *Schreb.*, andryala, crepis, hieracium, leontodon, prenanthes, chondrilla, lactuca, ſonchus, *apargia, *Scop.*, picris, ſcorzonera, tragopogon, *geropogon*. III. *Diſcoideæ*, gnaphalium, xeranthemum, ſtœhelina, tanacetum, matricaria, carpeſium, chryſanthemum, *pteronia*, baccharis, *oſmites*, conyza, inula, erigeron, *cineraria*, tuſſilago, doronicum, *arnica*, ſenecio, ſolidago, chryſocoma, aſter, *leyſera*, ſantolina, anthemis, anacyclus, cotula, *athanaſia*, achillea, *cacalia*, *perdicium*, bellis, ageratum, removed from oppoſitifolii, eupatorium, removed from oppoſitifolii, *ethulia*, *kuhnia*, *bellium*, *unxia*, *mutiſia*, *lavenia, *Soland. Sw.* *kleinia *Jacq.* Giſeke obſerves, that it is not eaſy to determine why Linnæus has given the name of diſcoideæ to this order, which nearly correſponds with his former corymbiferi; ſince the greater part of them are not diſcoid, in the uſual ſenſe of the word, but furniſhed with a ray. IV. *Not named by Linnæus.* Corymbium, removed from ſemifloſculi, helenium, othonna, and arctotis, removed from corymbiferæ, calendula, and oſteoſpermum, removed from oppoſitifolii, *ſclerocarpus, *Jacq.* V. *Oppoſitifoliæ*, *ſpilanthus*, bidens, verbeſina, ſigeſbeckia, coreopſis, ſilphium, tetragonotheca, *polymnia*, *trixis, *Swartz.*, helianthus, rudbeckia, milleria, buphthalmum, removed from corymbiferi, chryſogonum, melampodium, tridax, *pectis*, tagetes, removed from corymbiferi, *zinnia*, *calea*, *amellus*, *eclipta*, *baltimora*, hippia, *oedera*, *clibadium*, *jungia*, *relhania, *L'Herit.*, *boltonia, *L'Herit.*, *meyera, *Schreb.*, *phactuſa, *Gært.*, *galardia, *Lam.*, *berckheya, *Ehrh.*, *craſpedia, *Forſt.*, *didelta, *L'Herit.*, *tetranthus, *Swartz.*, *rolanda, *Rottb.*, *ſhawia, *Forſt.* VI. *Nucumentaceæ*, ſtoebe, and tarchonanthus, removed from corymbiferæ, *artemiſia*, *ſeriphium*, eriocephalus, removed from corymbiferæ, *filago*, *micropus*, *iva*, *parthenium*, *ambroſia*, *xanthium*, *ſtrumpſia*.

None of the plants of this order are poiſonous, except tagetes, doronicum, and arnica. Moſt of them are bitter and unpleaſant to the taſte, but poſſeſſed of ſtrengthening qualities as a medicine. Some, however, are leſs bitter and eſculent; and ſeveral others are rendered ſo by cultivation and blanching.

Vaillant, Juſſieu, and Ventenat have divided this order into three: *chicoraceæ*, *cinarocephalæ*, and *corymbiferæ*.

COMPOSITE NUMBERS, in *Arithmetic*, are ſuch as can be exactly divided by ſome ſmaller number or numbers, without leaving any remainder; ſuch as do not admit of this even diviſion, are called PRIME *numbers*, which ſee. The following table of compoſite and prime numbers under 100, ſhewing all their prime diviſors, will be found uſeful in a great variety of calculations.

	Units	1	2	3	4	5	6	7	8	9
Tens	0	1	2	3	2^2	5	2.3	7	2^3	3^2
1	2.5	11	$2^2.3$	13	2.7	3.5	2^4	17	2.3^2	19
2	$2^2.5$	3.7	2.11	23	$2^3.3$	5^2	2.13	3^3	$2^2.7$	29
3	2.3.5	31	2^5	3.11	2.17	5.7	$2^2.3^2$	37	2.19	3.13
4	$2^3.5$	41	2.3.7	43	$2^2.11$	$3^2.5$	2.23	47	$2^4.3$	7^2
5	2.5^2	3.17	$2^2.13$	53	2.3^3	5.11	$2^3.7$	3.19	2.29	59
6	$2^2.3.5$	61	2.31	$3^2.7$	2^6	5.13	2.3.11	67	$2^2.17$	3.23
7	2.5.7	71	$2^3 3^2$	73	2.37	3.5^2	$2^2.19$	7.11	2.3.13	79
8	$2^4.5$	3^4	2.41	83	$2^2.3.7$	5.17	2.43	3.29	$2^3.11$	89
9	$2.3^2.5$	7.13	$2^2.23$	3.31	2.47	5.19	$2^5.3$	97	2.7^2	$3^2.11$

In the above table, any number is to be ſought for in the angle of meeting of its *tens*, in the front column, and its *units* in the top line; thus, 23 will be found in the line with 2 at its beginning, and under three at the top. The prime numbers are diſtinguiſhed by larger figures, and the compoſite numbers have their component primes ſhewn, ſeparated by dots to expreſs, in this caſe, the ſign of multiplication, as is frequently done by the writers on ſeries; thus 84 is compoſed of the ſquare of 2 or 2^2, multiplied by 3 and by 7; 72 is compoſed of the cube of 2 into the ſquare of 3. Matter of curious reflection will be furniſhed by this table to ſuch as ſtudy the properties of numbers, by tracing the parallel lines in which each prime occurs; thus, in one diagonal of the above table, the whole of the multiples of 11 will be found, while 3^2 (or 9) will be found in the compoſition of every number in the other diagonal line; parallel to which, in every alternate line, the other multiples of 3 will be found. The fives and the twos will all be found to occur throughout every vertical column in which they occur at top; and under 0, they both occur in every line. This uſeful and curious table we found in M. Overend's manuſcripts, in the library of the Royal Inſtitution, where the moſt copious tables of compoſite and prime numbers may be ſeen, by thoſe who are curious in theſe matters.

COMPOSITE *Numbers*, in *Muſical Calculations*, are ſuch as are compoſed by the multiplication of the prime integers, 2, 3, and 5; all primes larger than theſe, or compoſite numbers into which ſuch enter, are not muſical numbers, but are irrational or ſurd in a muſical ſenſe. See Musical Numbers.

Composite, or *Roman Order*, in *Architecture*. This name is uſed to denote a kind of column whoſe capital is compounded of the Ionic and Corinthian forms; the vaſe or tambour of the capital being like that of the Corinthian order, and ornamented in the ſame manner, with two tiers of leaves, and with a ſimilar abacus; but to theſe are added Ionic volutes which ſupply the place of the caulicoli and ſeroles, proper to the Corinthian capital. See the plates of capitals. In other reſpects, in the ſhaft baſe and entablature, there is no uniform and aſſignable difference between the Compoſite and Corinthian, and we ſhall, in a ſubſequent portion of this article, examine what claims this compoſite has to be conſidered as a diſtinct order.

The principal remains of antiquity in which the compoſite capital is found, are the following; the arch of Titus, the arch of Septimius Severus, and the arch of the goldſmiths, the building commonly called the Temple of Bacchus, without the gate of Sta. Agneſa at Rome, the baths of Diocletian, the Baptiſterium of Conſtantine, which is ornamented with porphyry columns of the moſt exquiſite workmanſhip, removed from ſome more ancient edifice; the arch at Verona, and the chapel or baſilica at Niſmes.

This capital was therefore very popular among the Roman architects, but it does not by any means appear that they admitted a diſtinct compoſite order. A paſſage of Vitruvius will throw ſome light upon this point; this author, after deſcribing the capitals of the Doric, Ionic, and Corinthian orders, proceeds to obſerve, that "there are alſo other kinds of capitals called by various names, which are diſpoſed on the ſame columns, and which have no proper ſymmetry or relation to any ſeparate order of columns, but they are all derived and transferred from the Corinthian, Pulvinated (Ionic) or Doric orders, from whoſe ſymmetries they only differ in the little novelties of the ſculpture." In fact, the remains of Roman antiquity furniſh a vaſt variety of capitals, many of which are more remarkable and remote from the uſual orders, as well as more beautiful than the compoſite capital, and yet no architect has ever thought of erecting any of theſe into diſtinct orders. The capitals of the Temple of Concord at Rome, a very entire and conſiderable remain, are compoſite, being a melange of the Ionic and Doric; but no one has claimed the honours of an order for this ſtrange production.

The difference between the pretended Compoſite order and the Corinthian, exiſts merely in the capital; for neither in the remains of antiquity, nor in the works of modern artiſts, is there any decided, uniform, and characteriſtic difference in any other particular. But the capital, though an important member, is not of itſelf ſufficient to form an order, otherwiſe we ſhould reckon not five but hundreds; and a compoſition which has no appropriate proportions, no excluſive character, can only be regarded as a variety of that order with which it is perpetually liable to be confounded. The equivocal nature of this production has cauſed great embarraſſment to the ſyſtem-mongers of architecture; for while its later origin would lead them to place it laſt in their ſyſtems, and higheſt in their buildings, its heavineſs of appearance, in compariſon with the Corinthian order, ſeems to indicate a contrary arrangement. It is unneceſſary; for the three Grecian orders ſupply all the expreſſions which architecture is capable of giving with diſtinctneſs. The Doric is ſtrong, the Ionic elegant, and the Corinthian rich; while they admit all the modifications of theſe qualities that can be required; but as to the Compoſite, what is it but an exaggeration of the Corinthian, in which the attempt at ſuperior richneſs has only produced a degree of heavineſs.

It has been before obſerved, that the Romans affected no particular entablature to the compoſite capital. In the temple of Bacchus the cornice is entirely plain, with a ſwelled frieze. The arch of Septimius Severus has a cornice enriched with dentils extremely ſimilar to the Ionic of the temple of Fortuna Virilis, and the theatre of Marcellus; while the cornices of the arch of Titus, and the arch at Verona have both dentils and modillions, and the whole profile of the entablatures is preciſely in the ſtyle of the generality of Corinthian examples. Among the moderns, Palladio has imitated the frontiſpiece of Nero in his cornice and architrave; but he has omitted its beautiful frieze, and ſubſtituted a ſwelled one. Scamozzi's entablature being only one-fifth of the column, and much divided, has rather a trifling appearance, though the details are upon the whole well deſigned. Vignola's compoſite has nothing in it remarkable; the architrave differs but little from that of the frontiſpiece of Nero, and the cornice is nearly the ſame with that of his Ionic order. Serlio's entablature is extravagantly abſurd, being taken from the fourth order of the coliſeum, a compoſition well enough adapted for the termination of that gigantic edifice, but wholly diſproportionate to a ſingle order.

Composite *Stalk*. See Stalk.

COMPOSITIO Mensurarum, the title of an ancient ordinance for meaſures, not printed; it is mentioned in the ſtatute of 23 Hen. VIII. cap. 4.

COMPOSITION, in a general ſenſe, is the uniting or joining of ſeveral different things, ſo as to form one whole, called a *compound*.

The ſchoolmen diſtinguiſh two kinds of compoſition; the one *entitative*, which is between things of the ſame nature, *e. gr.* two or more drops of water: the other *eſſential*, when things of different kinds are joined, and thus conſtitute new things, or eſſences, different from any of the parts: and thus, ſay they, from the matter and the form of wood, ariſes wood; whoſe eſſence is very different from either of thoſe ingredients taken ſeparately.

Composition *of bodies*, in *Chemiſtry*. See Combination and Affinity.

Composition, in *Commerce*, a contract between an inſolvent debtor and his creditors; whereby the latter agree to accept a part of the debt, in compenſation for the whole, and give a general acquittance accordingly.

Composition *for Trees*, in *Gardening*, a ſubſtance diſcovered, prepared, and applied by Mr. Forſyth, for the purpoſe of removing diſeaſes, defects, and injuries in fruit and foreſt-trees. It is directed to be compoſed in the following manner, in his "Treatiſe on the Management of Trees."

"Take one buſhel of freſh cow-dung, half a buſhel of lime-rubbiſh of old buildings (that from the ceilings of rooms is preferable), half a buſhel of wood-aſhes, and a ſixteenth part of a buſhel of pit or river-ſand; the three laſt articles are to be ſifted fine before they are mixed; then work them well together with a ſpade, and afterwards with a wooden beater, until the ſtuff is very ſmooth, like fine plaſter uſed for the cielings of rooms."

It is adviſed that the trees ſhould be prepared for its application "by cutting away all the dead, decayed, and injured parts, down to the freſh ſound wood; leaving the ſurface of the wood very ſmooth, and rounding off the edges of the bark with a draw-knife, or other inſtrument, perfectly ſmooth, which muſt be particularly attended to; then lay on the plaſter about one eighth of an inch thick all over the part where the wood or bark has been ſo cut away, finiſhing off the edges as thin as poſſible: then take a quantity of dry powder of wood aſhes mixed with a ſixth part of the ſame quantity of the aſhes of burnt bones, put it into a tin box with holes in the top, and ſhake the powder on the ſurface of the plaſter, till the whole is covered over with it, letting it remain for half an hour to abſorb the moiſture; then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder till the whole plaſter becomes a dry ſmooth ſurface."

And he adds the following directions.

" All trees cut down near the ground ſhould have the ſurface made quite ſmooth, rounding it off in a ſmall degree as before-mentioned; and the dry powder directed to be uſed afterwards, ſhould have an equal quantity of powder of alabaſter mixed with it, in order the better to reſiſt the dripping of trees and heavy rains."

Such parts or portions of the compoſition as may be left for a future uſe " ſhould be kept in a tub or other veſſel, and urine of any kind poured on them, ſo as to cover the ſurface; otherwiſe the atmoſphere will greatly hurt the efficacy of the application."

And " where lime-rubbiſh of old buildings cannot be eaſily got, take pounded chalk, or common lime, after having been ſlaked a month at leaſt."

It is further remarked by the author, that " as the growth of the tree will gradually affect the plaſter, by raiſing up its edges next the bark, care ſhould be taken, when that happens, to rub it over with the finger when occaſion may require (which is beſt done when moiſtened by rain), that the plaſter may be kept whole, to prevent the air and wet from penetrating into the wood."

But " as the beſt way of uſing the compoſition is found, by experience, to be in a liquid ſtate," Mr. Forſyth adviſes that it ſhould " be reduced to the conſiſtence of pretty thick paint, by mixing it up with a ſufficient quantity of urine and ſoapſuds, and be laid on with a painter's bruſh. The powder of wood-aſhes and burnt bones is to be applied as before directed, patting it down with the hand."

It is alſo further adviſed, that " when trees are become hollow, to ſcoop out all the rotten, looſe, and dead parts of the trunk to the ſolid wood, leaving the ſurface ſmooth; then to cover the hollow, and every part where the canker has been cut out, or branches lopped off, with the compoſition; and as the edges grow, to take care not to let the new wood come in contact with the dead, part of which it may be ſometimes neceſſary to leave; but to cut out the old dead wood as the new advances, keeping a hollow between them, to allow the new wood room to extend itſelf, and thereby fill up the cavity, which it will do in time, ſo as to make it as it were a new tree."

And if the cavity be large, to cut away as much at one operation as will be ſufficient for three years. But in this to " be guided by the ſize of the wound, and other circumſtances. When the new wood, advancing from both ſides of the wound, has almoſt met, to cut off the bark from both the edges, that the ſolid wood may join, which, if properly managed, it will do, leaving only a ſlight ſeam in the bark. If the tree be very much decayed, not to cut away all the dead wood at once, which would weaken the tree too much, if a ſtandard, and endanger its being blown down by the wind. It will conſequently be neceſſary to leave part of the dead wood at firſt, to ſtrengthen the tree, and to cut it out by degrees as the new wood is formed. If there be any canker, or gum oozing out, the infected parts muſt be pared off, or cut out with a proper inſtrument. When the ſtem is very much decayed and hollow, it will be neceſſary to open the ground and examine the roots." See DRESSING *of Trees*.

Various intereſting facts and obſervations on the advantage and utility of this compoſition in the removal of the diſeaſes of different ſorts of trees, may be ſeen below, as taken from Mr. Forſyth's valuable " Treatiſe on the Culture and Management of Fruit and Foreſt Trees."

It is ſtated by Mr. Forſyth as being " the received opinion and common practice of moſt profeſſional men, to prune or lop their trees, from the month of October, when the juices have been exhauſted by the ſummer foliage, autumnal fruit, and general nouriſhment of the body of the tree, until the month of March, when the ſap or juices, re-invigorated by nature during the winter's repoſe, begin to re-aſcend and perform the annual function of clothing it with freſh foliage, bloſſoms, and fruit. The reaſon of this practice is, he ſays, that the ſap being fallen at that ſeaſon of the year, it has been conſidered as the moſt proper period to lop off all ſuperfluous growths, and the efforts of nature to heal the wounds thus neceſſarily given (before the riſing of the ſap in the following ſpring), have been judged beſt for the ſafety and health of the tree. The danger of performing this ſervice when the juices are in a more vigorous flow, as in the months of May, June, and July, has been dreaded, from a fear of its occaſioning a waſte of the nutritive juices, diſcharging themſelves through the wound, to the impoveriſhment and injury, if not the ruin of the tree." And it is added, that " the pruning of fruit-trees, and the lopping off large branches from foreſt-trees during the winter ſeaſon, has alſo been frequently attended with great hurt and impediment to their health and vegetation; the wounds being expoſed to all the rigours of an inclement ſeaſon, and thereby contracting thoſe diſeaſes which contain the principles of decay. Hence it is, that ſuch numbers of foreſt-trees are continually injured in their value for public uſes, either by unſkilful management, or purpoſed depredation, or by the violence of boiſterous winds, when their limbs and branches being torn off, the trees are left in that unprotected ſtate to imbibe the ſeeds of decay and rottenneſs, which will in time pervade their very heart, and render them unfit for any of thoſe valuable purpoſes for which nature, by their frame and texture, appears to have deſigned them." And "it may alſo be obſerved, that where branches have been cut off from the body of the tree, even at the diſtance of two or more feet from the trunk, with a view to prevent injury to the timber, even that method has not been found effectual to ſave the tree from very material detriment; as the remaining ſtem of the branch ſo cut away, dying ſoon after, becomes a ready conduit for conveying pernicious moiſture and diſeaſe to that part of the tree with which it is connected; and ſo on, in time, to the whole."

But he ſuppoſes " the practice of others in lopping their trees cloſe to the trunk, and dreſſing the part ſmooth and even, has leſs objections than the former; nevertheleſs, even according to this method, the tree is liable to injury. The effort of nature to heal the wounds thus given, diſcovers itſelf by encircling the wound with a kind of callus or lip, which increaſing in ſize, and ſwelling out from the annual flow of the juices, forms a hollow or cavity of the central part, where the rain or ſnow is very apt to lodge; and penetrating between the bark and wood, dried and cracked by a hard froſt, or a warm ſun, promotes that fermentation with the natural juices, which is the certain ſource of diſeaſe and decay." It is ſuggeſted that " young, healthful, and vigorous trees, when they have been injured by being wantonly cut through the bark, or from other cauſes, will ſometimes recover themſelves, and, to all outward appearance, be reſtored to their original ſoundneſs; but when cut into planks and boards, internal blemiſhes and faults are diſcovered in them, which appear to have been occaſioned by the early injuries which the tree had received; the texture of the wood not uniting where the wound was originally given; though, from the youthful vigour of nature, the bark has cloſed, and an external cure been evidently performed on ſuch trees.

The compoſition is a moſt efficacious remedy to prevent theſe evils with all their deſtructive conſequences, and to reſtore ſound timber where the ſymptoms of decay are already apparent, which being applied in the manner directed, “to the wound or injured part, will infallibly prevent the bleeding of trees, or the oozing of juices through the wounds of limbs or branches that have been cut off in the middle of ſummer, when they are in their higheſt vigour, and moſt rapid flow of vegetation; by which means, any waſteful diſcharge of the juices is prevented, and they are duly confined to their natural operations of giving nouriſhment, growth, and fertility, to their reſpective bodies. By employing this remedy, trees of all kinds, whether in gardens or orchards, in parks or foreſts, may, he ſays, with greater ſafety and advantage be pruned or lopped in the ſpring, or early in the ſummer, than in the winter ſeaſon; as the compoſition, when properly applied, repels the flow of the juices through the wound, cauſes a more active vegetation, and aſſiſts nature more powerfully in healing the wound at the time the ſap is in full vigour, than when it is on the decline, as in autumn and winter ſeaſons.”

The writer conſiders it alſo neceſſary to remark, further, “that both fruit and foreſt-trees (particularly thoſe which grow in the ſhade) are very liable to be affected with diſorders proceeding from the growth of liverwort, and various kinds of moſs, that adhere to the outer bark of the tree, and frequently gain a conſiderable thickneſs, that not only prevents the natural flow of the juices, but cauſes a ſtagnation in the circulation and brings on decay; which, after deſtroying the outer bark, penetrates by degrees deeper into the wood. Where this circumſtance is obſerved, care ſhould be taken to clear the whole bark of the tree from theſe growths; and where it is infected, to ſcrape or pare it away. When the body of the tree is thus cleanſed from infection, the compoſition may be applied to the parts ſo cleanſed, to cloſe the pores of the wood; when the tree will ſoon acquire a freſh bark, and improved health and vegetation.”

The author is “confirmed in theſe opinions by the many experiments and various trials that he has made, to aſcertain, by the moſt poſitive proofs, the properties of this compoſition, before he ventured to offer it to the public attention.” “Indeed, every year's experience has increaſed his conviction of its general utility, when properly applied to the purpoſes for which it is recommended.” In order to give a more complete illuſtration of its virtues, and to place the advantages ariſing from it in a ſtronger light, he ſtates a few of the very numerous experiments that he has made on the foreſt-trees in his majeſty's gardens at Kenſington, where the ſalutary effects of it are extremely evident.

It is remarked that “the firſt trials of its efficacy were made on ſome very large and ancient elms, many of which were in a moſt decayed ſtate, having all their upper parts broken, by high winds, from their trunks, which were withal ſo hollow and decayed, that a ſmall portion alone of the bark remained alive and ſound. Of theſe trees he cut away at firſt a part only of the rotten ſtuff from the hollow of the tree, and then applied the plaſter to the place where the operation had been performed, by way of an internal coat. In a ſhort time, however, the efforts of nature, with a renovated flow of the juices, were clearly diſcernible in their formation of new wood, uniting with and ſwelling as it were from the old, till it became a ſtrong ſupport to that part of the tree where the compoſition had been applied. He then cut away more of the rotten wood from the inſide, applying the plaſter in the ſame manner, with the ſame good effects, and continued to uſe the knife in proportion to the acquiſition of new wood; ſo that from the tops of the decayed and naked trunks, ſtems have, he ſays, actually grown of about thirty feet in height, in the courſe of ſix or ſeven years from the firſt application of the compoſition; an incontrovertible proof of its good effects in reſtoring decayed vegetation in ſuch caſes.”

And he adds, that “many other elm trees, which had received hurts from bruiſes and other cauſes, and where diſeaſe and decay were already evident, after cutting away all the infected part, and duly applying the plaſter, were ſo completely healed, that the outline of the wound is ſcarcely diſcernible on the bark, and the new wood is as perfectly united to the old, as if it had been originally formed with the tree.”

It is ſtated that “of oak trees alſo, which had received very conſiderable damage from various accidents, as blows, bruiſes, and cutting of deep letters, the rubbing off of the bark by the ends of rollers, or wheels of carts, and mutilated branches, a perfect cure has been made, and ſound timber produced. The acidity, or corroſive quality of the juice of oak-trees, when obſtructed in their circulation from any of the cauſes already mentioned, and fermenting with the wet and moiſture imbibed by the wounds from the atmoſphere, will bring on diſeaſe, and promote decay; for, notwithſtanding the hard texture of the oak, when once the principles of decay begin to operate, the acrimonious juices feed the diſeaſe, and accelerate its progreſs, as much, perhaps, as in trees of a ſofter quality and texture, but when the diſeaſed or injured part is entirely cut away to the freſh ſound wood, and the compoſition properly laid on, as perfect a cure has been made as he has already related in the recovery of elm trees.”

The writer likewiſe further ſtates, that “various experiments have alſo been made on other foreſt trees, as aſh, limes, cheſnuts, and ſycamores, that had received the ſeveral injuries to which they are expoſed; as well as many of the reſinous kinds, ſuch as the cedar of Lebanon, and others of the pine tribe: in all of which he has experienced a degree of ſucceſs that exceeded his moſt ſanguine expectations. And as he feels a ſtrong ſolicitude to render his experiments of the moſt extenſive advantage to the community, and in particular to the proprietors of landed eſtates throughout the kingdom, he begs leave to recommend to their particular attention, that all foreſt trees, whether felled with a ſaw or an axe, may be cut near to the ground; at the ſame time carefully preſerving the ſtump and roots from any further injury. The ſurface may then be made quite ſmooth, and the compoſition be ſpread over the whole, according to directions already given. But in theſe caſes the compoſition ſhould have an equal quantity of the powder of alabaſter mixed with the dry powder generally directed to be uſed after it is laid on, in order to render the ſurface harder, and of courſe better able to reſiſt the bad effects of the dripping of trees, of rain, froſt, and ſnow; an addition which is by no means neceſſary in the uſual application to the ſides of trees.” He concludes that, “in conſequence of this proceſs, the vigour of the roots will operate ſo powerfully in the courſe of the ſucceeding ſpring, that a conſiderable number of buds or branches will ſhoot forth round the ſtump, which, with proper care and attention, may be trained to many valuable purpoſes, either ſtraight or crooked, for knee timber, or other uſes; and, by retaining only ſo many of theſe ſhoots as are deſigned to grow for any particular intention, more than one half will be ſaved, in point of time, according to the proportions of common growth; for, if a young tree be planted in a ſoil equal in quality to the ſtate of the old ſtump, the roots growing from the latter will, in eight or ten years, attain to a ſize which the ſingle plant will hardly acquire in twice that period. There are alſo many uſeful purpoſes of huſbandry, as hop-poles and other poles uſed on various occaſions, for which a number of ſhoots may be trained from one ſtump, whoſe fertile juices will ſhortly rear a healthy and numerous offſpring around it. Very particular attention, however, ſhould, he ſays, be paid to regulate the number, according to the ſize and vigour of the ſtump. It would certainly be proper to leave more of them at firſt than are intended to be reſerved for final uſe, in order to draw up the ſap; if too few are left, they will be liable to burſt, from the ſuperabundant flow of the juices from the old ſtock; to prevent which inconvenience they ſhould be cut away by degrees, always applying the compoſition as they are cut, and leaving the fineſt ſtem to produce the new tree, and will, in time, cover the old ſtump, and leave nothing but a faint kind of cicatrix at the junction of the old and new part of the tree."

He thinks it "needleſs for him to inſiſt on the great advantages which land proprietors and farmers will derive from this method of managing their woods and coppice-grounds, wherever they may be. In many counties of England, coppice, or underwood, is an article in very great demand for charcoal, common fuel, or the purpoſes of particular manufactories, as well as to furniſh a variety of articles for huſbandry and domeſtic conveniences." And its advantages in a national as well as ornamental point of view, are ſtill more obvious. See Canker.

Composition, in *Grammar*, denotes the joining of two words together; or prefixing a particle to another word, to augment, diminiſh, or change its ſignification. See Word, &c.

Composition, in *Law*, an agreement or contract made between the owner of lands and the parſon or vicar, with the conſent of the ordinary and the patron, that ſuch lands ſhall for the future be diſcharged from payment of tithes, by reaſon of ſome land or other real recompence, given to the parſon, in lieu and ſatisfaction thereof. Land may be exempted from the payment of tithes, where compoſitions have been made; and real compoſitions for tithes are to be made by the concurrent conſent of the parſon, patron, and ordinary. Real compoſitions are diſtinguiſhed from perſonal contracts; for a compoſition called a perſonal contract is only an agreement between the parſon and the pariſhioners, to pay ſo much inſtead of tithes: and though ſuch agreement is confirmed by the ordinary, yet (if the parſon be not a party) that doth not make it a real compoſition, becauſe he ought to be a party to the deed of compoſition. (Marſh's Rep. 87.) This kind of compoſition was permitted by law, becauſe it was ſuppoſed that the clergy would be no loſers by ſuch compoſition; ſince the conſent of the ordinary, whoſe duty it is to take care of the church in general, and of the patron, whoſe intereſt it is to protect that particular church, were both made neceſſary to render the compoſition effectual; and hence have ariſen all ſuch compoſitions as exiſt at this day by force of common law. But, experience ſhewing that even this caution was ineffectual, and the poſſeſſions of the church being, by this and other means, every day diminiſhed, the diſabling ſtatute 13 Eliz. c. 10, was made, which prevents, among other ſpiritual perſons, all parſons and vicars from making any conveyances of the eſtates of their churches, other than for three lives or twenty-one years. So that now, by virtue of this ſtatute, no real compoſition made ſince the 13th Eliz. is good for any longer term than three lives, or twenty-one years, though made by conſent of the patron and ordinary; which has, indeed, effectually demoliſhed this kind of traffic; ſuch compoſitions being now rarely heard of, unleſs by authority of parliament. See Modus.

Compoſition is ſometimes uſed for "deciſio litis." Accordingly compoſitions were anciently allowed for crimes and offences, even for murder. By this expedient it was propoſed to reſtrain the violence of private revenge. The cuſtom may be traced back to the ancient Germans (ſee Tacit. de Mor. German. c. 21.) and prevailed in other uncivilized nations. The nature of crimes and offences was eſtimated by the magiſtrate, and the ſum due to the perſon offended was aſcertained with a minute, and often a whimſical, accuracy. Rotharis, the legiſlator of the Lombards, who reigned about the middle of the 7th century, diſcovers his intention both in aſcertaining the compoſition to be paid by the offender, and in increaſing its value: it is, ſays he, that the enmity may be extinguiſhed, the perſecution may ceaſe, and peace may be reſtored. About the beginning of the 9th century, Charlemagne ſtruck at the root of the evil, and enacted, "that when any perſon had been guilty of a crime, or had committed an outrage, he ſhould immediately ſubmit to the penance which the church impoſed, and offer to pay the compoſition which the law preſcribed, and if the injured perſon or his kindred ſhould refuſe to accept of this, and preſume to avenge themſelves by force of arms, their lands and properties ſhould be forfeited. Tavernier relates, that in Perſia, a murderer is ſtill delivered to the relations of the perſon whom he has ſlain, who put him to death with their own hands; and if they refuſe a ſum of money as a compenſation, the ſovereign cannot pardon the murderer. Monteſq. Sp. of Laws, vol. ii. p. 382. Robertſon's Hiſt. of Ch. V. vol. i. p. 334, &c.

Composition, in *Logic*, is a method of reaſoning, wherein we proceed from ſome general ſelf-evident truth, to other particular and ſingular ones.

The method of compoſition, called alſo *ſyntheſis*, is juſt the reverſe of that of reſolution, or *analyſis*.

Reſolution is the method whereby we ordinarily ſearch after truth; compoſition, that whereby a truth found, is diſcovered and demonſtrated to others; reſolution is the method of inveſtigation; compoſition, of demonſtration.

The method of compoſition is that uſed by Euclid, and other geometricians; reſolution, that uſed by algebraiſts and philoſophers. The two methods differ, juſt as the methods of ſearching a genealogy; which are either by deſcending from the anceſtors to the poſterity, or by aſcending from the poſterity to their anceſtors: each have this in common, that their progreſſion is from a thing known, to another unknown.

The method of compoſition is beſt obſerved by the mathematicians: the rules which are, 1. To offer nothing but what is couched in clear and expreſs terms; and to that end, to begin with definition. 2. To build only on evident and clear principles; to that end, to proceed from axioms or maxims. 3. To prove demonſtratively all the concluſions that are drawn hence; and to this purpoſe, to make uſe of no arguments or proofs, but definitions already laid down, axioms already granted, and propoſitions already proved; which ſerve as principles to things that follow.

Composition *of ideas*, is an operation of the mind, whereby it combines ſeveral of its ſimple ideas into complex ones.

Under the ſame operation may likewiſe be reckoned that of enlarging; whereby we put ſeveral ideas together of the ſame kind, as ſeveral units to make a dozen.

In this, as in others, brutes come far ſhort of men; for though they take in and retain ſeveral combinations of ſimple ideas; as poſſibly, a dog does the ſhape, ſmell, and voice of his maſter; yet theſe are rather ſo many diſtinct marks whereby he knows him, than one complex idea, made out of thoſe ſimple ones.

An ingenious writer has ſuggeſted the impropriety of the phraſe "compoſition of ideas," adopted by Mr. Locke, alleging it is merely a contrivance of language, and that the only compoſition is in the terms; and that it is as improper to ſpeak of a complex idea, as it would be to call a conſtellation a complex ſtar. He further adds, that they are not ideas, but merely terms, which are general and abſtract. Whatever, he ſays, the immortal author of the "Eſſay on Underſtanding," has juſtly concluded in his reaſoning on this ſubject will hold equally true and clear, if we ſubſtitute the compoſition, &c. of terms, wherever he has ſuppoſed a compoſition, &c. of ideas. If upon ſtrict examination this ſhould appear to be the caſe, we ſhall need no other argument againſt the compoſition of ideas: it being exactly ſimilar to that unanſwerable one which Mr. Locke himſelf declares to be ſufficient againſt their being innate. For the ſuppoſition is unneceſſary: every purpoſe for which the compoſition of ideas was imagined being more eaſily and naturally anſwered by the compoſition of terms; whilſt at the ſame time it likewiſe clears up many difficulties, in which the ſuppoſed compoſition of ideas neceſſarily involves us. This writer further adds, that it is an eaſy matter, upon Mr. Locke's own principles, and a phyſical conſideration of the ſenſes and the mind, to prove the impoſſibility of the compoſition of ideas. Tooke's Diverſions of Purley, pt. i. p. 37, &c.

Composition, in *Mathematics*, is the taking of a given number of quantities, out of as many equal rows of different quantities, one out of every row; and combining them together. Here no regard is had to their places; and it differs from combination, in which there is but one row of things.

I. "The number of compoſitions of n things taken out of n rows, each row conſiſting of m things, is m^n, or the n^{th} power of m."

Let there be any number of rows, ſuch as thoſe annexed. It is plain the number of ſingle things as a, b, c, d, is m or m^1.

$$\left.\begin{array}{l}\\ \\ \end{array}\right\} \begin{array}{llll} a, & b, & c, & d, \\ e, & f, & g, & h, \\ i, & k, & l, & m. \end{array}$$

Then the number of combinations of every 2 is had by joining each quantity in the ſecond row to all the quantities in the firſt, which will make as many times m as there are things in the ſecond row, or m times m, that is m^2, for all the two's. Again, taking in the third row; there will be as many times m^2, as there are things in the third row, that is, m times mm, or m^3, for the compoſition of three things.

After the ſame manner, if a fourth row was taken in; all the combinations of every four would be m^4, and ſo on: and, therefore, univerſally, when n rows are taken in, the number of combinations will be m^n, which is the number of compoſitions. Hence it follows, 1. That the number of compoſitions of all the one's, two's, three's, &c. to n, is $\frac{m^n - 1}{m - 1} m$. For $\frac{m^4 - 1}{m - 1} = m^3 + m^2 + m + 1$. And $\frac{m^4 - 1}{m - 1} m = m^4 + m^3 + m^2 + m$, as will appear by diviſion, or, in general, $\frac{m^n - 1}{m - 1} m = m^n + m^{n-1}$, &c. to m = compoſitions of all the one's, two's, three's, &c. to n.

2. Hence may be found the compoſition of n things out of m, as follows: Involve m to the n^{th} power for the anſwer.

E. G. 1. How many compoſitions may be had, of 3 letters out of 20?

Anſ. $20^3 = 8000$. In this caſe there ſhould be three different alphabets.

E. G. 2. How many changes are there on throwing four dice?

Anſ. $6^4 = 1296$.

II. "If there be m rows of quantities given, having the ſame quantities, and the ſame number of them, as a, b, c, d, &c. to find the number of compoſitions of m things taken out of the m rows; for any given form of theſe quantities, as $a^t\, b^v\, c^w\, d^x$, &c.

Rule. Put V = variations of the things $a^t\, b^v\, c^w\, d^x$; and A = variations or alternations of the indexes, t, v, w, x. (See Changes and Permutation.) Then will AV = the number of compoſitions required.

For let the different rows in the laſt propoſition be made all alike, or the firſt row m times repeated, as here. And let the number of things propoſed be $a^3\, b^2\, c$, and firſt let the index 3 be fixed to a and 2 to b, &c. Now, ſince a^3 may be taken out of any three rows, and b^2 out of any two remaining rows;

$$\left.\begin{array}{l}\\ \\ \\ \\ \\ \\ \end{array}\right\} \begin{array}{llll} a, & b, & c, & d, \\ a, & b, & c, & d, \\ a, & b, & c, & d, \\ a, & b, & c, & d, \\ a, & b, & c, & d, \\ a, & b, & c, & d, \\ a, & b, & c, & d. \end{array}$$

and c out of the laſt remaining row; therefore, there will be ſo many ways of taking theſe letters, as each of them can be placed in different rows, that is, in different places or ſituations; for the varying of the rows is the ſame thing as the varying of the places of the letters; and, conſequently, the different ways of taking them out of the ſeveral rows is equal to the number of variations or permutations of theſe letters; which number is = V. And this will hold as long as the indexes are fixed to theſe particular letters, and to none elſe. But ſince, in any one form, as $a^3\, b^2\, c$, that form will comprehend as many caſes as there can be variations in ſhifting the indexes from one letter to another; therefore, there will be ſo many times V, as is the number of theſe variations. Therefore, if A be = the number of variations, or alternations, of the indexes, 3, 2, 1; or, in general, of t, v, w, x; then AV will be the whole number of compoſitions, which that particular form will admit of.

Hence, 1. In any $a^t\, b^v\, c^w\, d^x$, where the indexes are fixed invariably to their particular letters; the number of compoſitions V will be $= \frac{1 \times 2 \times 3 \times 4 \ldots\text{ to } m}{1 . 2 . 3 \ldots t \times 1 . 2 . 3 \ldots\text{ to } v \times \text{\&c.}}$

2. If n = the number of different letters in any form, $a^t\, b^v\, c^w\, d^x$, &c.; then the whole number of compoſitions for that form will be $= \frac{1 . 2 . 3 \ldots\text{ to } n}{\text{RS, \&c.}}$ $\frac{1 . 2 . 3 \ldots\text{ to } m}{1 . 2 \ldots t \times 1 . 2 \ldots v \times \text{\&c.}}$ where R = 1 . 2, or 1 . 2 . 3, &c. according as any index is twice or thrice, &c. repeated; and the like for S, and ſo on.

E. G. 1. How many compoſitions are in the form $a^3\, b^2\, c$? Here $n = 3$, $m = 6$, $t = 3$, $v = 2$, $w = 1$: and in this caſe there is no repetition of indexes.

Anſ. $1 . 2 . 3 \times \frac{1 . 2 . 3 . 4 . 5 . 6}{1 . 2 . 3 \times 1 . 2} = 6 \times 60 = 360.$

E. G. 2. How many compoſitions are in the form $a^2\,b^2\,c$? Here $n = 3$, $m = 5$, $t = 2$, $v = 2$, $w = 1$. The index 2 is twice repeated.

Anſ. $\frac{1 . 2 . 3}{1 . 2} \times \frac{1 . 2 . 3 . 4 . 5}{1 . 2 \times 1 . 2} = 3 \times 30 = 90.$

E. G. 3. To find the compoſitions in the form $a^3\,b^3$. Here $n = 2$, $m = 6$, $t, v = 3$, $w = 0$. The index 3 is twice repeated; and the letters *a, b* thrice.

Anſ. $\frac{1 . 2}{1 . 2} \times \frac{1 . 2 . 3 . 4 . 5 . 6}{1 . 2 . 3 \times 1 . 2 . 3} = 1 \times 20 = 20.$

E. G. 4. To find the number of compoſitions of the form $a^3\,b^3\,c^2\,d^2$. Here $n = 4$, $m = 10$, $t, v = 3$, $w, x = 2$. The index 3 is twice repeated, and alſo the index 2. The letters *a, b* are thrice repeated; and *c, d* twice.

Anſ. $\frac{1 . 2 . 3 . 4}{1 . 2 \times 1 . 2} \times \frac{1 . 2 . 3 . 4 . 5 . 6 . 7 . 8 . 9 . 10}{1 . 2 . 3 \times 1 . 2 . 3 \times 1 . 2 \times 1 . 2} = 6 \times 25200 = 151200.$

E. G. 5. How many compoſitions in the form $a^5\,b^3\,c^3\,d\,e\,f$? Here $n = 6$, $m = 14$, $t = 5$, $v, w = 3$, $x = 1$. The index 3 is twice repeated, and the index 1 thrice: the letter *a* five times repeated; and *b* and *c* thrice.

Anſ. $\frac{1 . 2 . 3 . 4 . 5 . 6}{1 . 2 . 3 \times 1 . 2} \times \frac{1 . 2 . 3 . 4 . 5 . 6 . 7 . 8 . 9 . 10 . 11 . 12 . 13 . 14}{1 . 2 . 3 . 4 . 5 \times 1 . 2 . 3 \times 1 . 2 . 3} = 60 \times 20180160 = 1210809600.$ So prodigiouſly do the numbers increaſe in theſe operations. See Combination and Composite *numbers*.

Composition *of motion*, in *Mechanics*, is an aſſemblage of ſeveral directions of motion, reſulting from powers acting in different, though not oppoſite lines.

If a point move or flow according to one and the ſame direction, whether that motion be equable or not, yet it will ſtill keep the ſame right line; the celerity alone being changed, *i. e.* increaſed, or diminiſhed, according to the forces with which it is impelled. If the directions be oppoſite, as one, *e. gr.* directly downward, the other upward, &c. yet ſtill the line of motion will be the ſame.

But if the compounding motions be not according to the ſame line of direction, the compound motion will not be according to the line of direction of any of them, but in a different one from them all; and this either ſtraight or crooked, according as the direction or celerities ſhall require.

If two compounding motions be each of them equable, the line of the compound motion will ſtill be a ſtraight line; and this, though the motions be neither at right angles one to another, nor equally ſwift, nor (each to itſelf) equable; provided that they be but ſimilar; that is, both accelerated and retarded alike.

Thus, if the point *a* (*Pl.* XV. *Mechanics. fig.* 1.) be impelled equally with two forces; *viz.* upwards, towards *b*, and forwards, towards *d*; it is plain, that when it is gone forwards as far as *a c*, it muſt of neceſſity be gone upwards as far as *c e*; ſo that were the motions both equable, it would always go on in the diagonal *a e c*.

Nay, ſuppoſe the motions unequal as to celerity, ſo, *v. gr.* as that the body move twice as faſt upwards as forwards, &c. yet ſtill it muſt go on in the diagonal *a c*; becauſe the triangles *a e c, a e c,* &c. and *a c d* will ſtill be ſimilar, being as the motions are: and it will have deſcribed the diagonal in the ſame time which it would have required to deſcribe either of the ſides ſingly.

But, if the motions be diſſimilar, then the *compound* motion muſt be a curve.

And, if a body, as *b* (*fig.* 2.) be impelled or drawn by three different forces, in the three different directions *b a, b c,* and *b d,* ſo that it yields to none of them, but continues in *æquilibrio*: then will thoſe three powers or forces be to one another, as three right lines drawn parallel to thoſe lines, expreſſing the three different directions, and terminated by their mutual concourſes.

Let *b e* repreſent the force by which the body *b* is impelled from *b* to *a*; then will the ſame right line *b e* repreſent alſo the contrary equal force, by which it is impelled from *b* to *e*: but by what hath been ſaid before, the force *b e* is reſolvable into the two forces acting according to the two directions *b d* and *b c*, to which the other impelling from *b* to *e*, is as *b e* to *b d*, and *b c* or *de*, reſpectively.

So likewiſe two forces, acting without the directions *b d, b c,* and being equipollent to the force acting without the direction *b c*, from *b* to *e*; will be to the force acting according to the direction *b e*, from *b* to *e*, as *b d, b c,* to *b e*: and therefore, the forces acting in the directions *b d, b c,* and equipollent to the force acting in the direction *b e*, are to the force acting in the direction *b e*, as *b d, b c,* or *de,* to *b e*: that is, if a body be urged by three different equipollent powers in the directions *b a, b d,* and *b c*; theſe three forces ſhall be to one another as *b e, b d,* and *d e*, reſpectively.

This theorem, with its corollaries, Dr. Keill obſerves, is the foundation of all the new mechanics of M. Varignon: by help of which may the force of the muſcles be computed, and moſt of the mechanic theorems in Borelli, De Motu Animalium, be immediately deduced. See Motion.

Composition *of proportion*.—If there be two ratios, wherein the antecedent of the firſt is to its conſequent, as the antecedent of the other is to its conſequent; then, by compoſition of proportion, as the ſum of the antecedent and conſequent of the firſt ratio, is to the antecedent, or the conſequent, of the firſt; ſo is the ſum of the antecedent and conſequent of the ſecond ratio, to the antecedent, or the conſequent, of the ſecond.

E. gr. If A : B : : C : D; then by compoſition, A+B : A or (B) : : C+D : C or (D). See Proportion.

Composition *of ratios*, in *Arithmetic* and *Algebra*, is performed by multiplying the quantities or exponents of two or more ratios together; the product is then ſaid to be compounded of the ratios whoſe components were multiplied. Thus, if the quantities or exponents of the ratios *a* to *b*, *c* to *d*, *e* to *f*, be multiplied, we ſhall have $\frac{a}{b} \times \frac{c}{d} \times \frac{e}{f} = \frac{ace}{bdf}$. And the ratio *a c e* to *b d f*, is then ſaid to be compounded of the ſeveral ratios *a* to *b*, *c* to *d*, *e* to *f*, &c. Thus alſo the ratio of 10 to 12, is compounded of the ratio 2 to 3, and of 5 to 4; for $\frac{2}{3} \times \frac{5}{4} = \frac{10}{12}$.

This operation is by ſome called *addition* of ratios. See Ratio.

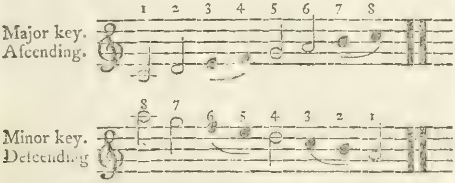
Composition, in *Muſic*, implies harmony, muſic in different parts, according with each other; and by the mixture of concords and diſcords embelliſhing melody, and communicating at once, to a well organized ear, the double delight ariſing from the union of the two great conſtituent ingredients in muſic, Melody and Harmony. To be able to write down or dictate a melody or ſingle part, does not exalt its author to the rank of compoſer; though many have aſſumed that title, who have not been poſſeſſed of ſcience ſufficient to make a baſe to a ballad or minuet.

As the term *compoſition* implies the union of various ingredients we ſhall endeavour in the important article Counterpoint,

TERPOINT, from our own knowledge, and from the precepts and practice of the greateſt maſters of the art, to deſcribe theſe ingredients, and point out their legitimate uſe. See COUNTERPOINT, which is ſo nearly ſynonymous with *Compoſition*, that we know not how to ſeparate them.

We take it for granted, before a muſical ſtudent is inflamed with the ambition of becoming a *compoſer*, that he is perfectly acquainted with the elements of the art; that he has read, or at leaſt heard, the principal productions of great maſters; that he knows intervals, and their relation to the key note and diſtance from every other ſound of the ſcale. See SCALE and INTERVAL. That he knows the different meaſures or kinds of time in muſic, nor is unacquainted with rhythm, nor where the accents of each bar ſhould be placed. See TIME, ACCENT, and MEASURE. That he knows and feels the difference between concords and diſcords; is offended with falſe intonation, and inſtruments out of tune; feels ſomething wrong in the regular ſucceſſion of two ſharp 3ds or 6ths; two 5ths or two common chords riſing or falling one degree; that he knows the compaſs and genius of the voice or inſtrument for which he writes. But we muſt not take too much for granted, or, in order to ſave ourſelves trouble, teaze our readers with too many references to articles connected with *compoſition*; we ſhall therefore refer our readers to the article *Counterpoint*. (which we have laboured with great zeal) for the mechanical rules of compoſition; firſt reminding the young ſtudent, that the ſcale of eight notes aſcending and deſcending, which repreſents the whole ſyſtem in a major key, conſiſts of 5 tones and 2 ſemitones, the 8th note being a recurrence of the ſame letter, and nearly the ſame ſound, is included in the ſame harmony as the key note or principal baſe.

Keys are denominated major or minor, ſharp or flat, from the ſituation of the ſemitones. Let C ♮ repreſent all major keys, and A ♮ the minor. In the major keys, the two ſemitones lie from the 3d to the 4th, and 7th to the 8th; and in minor keys, from the 2d to the 3d, and 5th to the 6th, aſcending in the major, and to avoid accidental ſharps, deſcending in the minor, thus:



A ſharp or flat at the clef, or an accidental ſharp or flat in the middle of a melody, changes the place of the firſt ſemitone; and two ſharps or two flats change the place of both,

Of theſe eight notes, ſome are termed *concords*, and ſome *diſcords*. Of the concords, ſome are *perfect*, and cannot be changed by an accidental ſharp or flat, without becoming diſcords. Theſe are the 4th, 5th, and 8th, which furniſh, when uſed in the lower part of the ſcale, a baſe to the regular aſcent in the treble. See SCALE, FUNDAMENTAL BASE, and COMPOSER.

COMPOSITION, in *Oratory*, the order and coherence of the parts of a diſcourſe.

As a part of general *elocution*, (which ſee) it regards the turn and harmony of the periods: and therefore to *compoſition* belong, both the artful joining of the words, whereof the ſtyle is formed, and whereby it is rendered ſoft and ſmooth, gentle and flowing, full and ſonorous; or the contrary: and the order, which requires things firſt in nature and dignity, to be put before thoſe of inferior conſideration.

Compoſition conſiſts of four parts; which rhetoricians call PERIOD, ORDER, JUNCTURE, and NUMBER, which ſee reſpectively. Ward's Oratory, vol. i. p. 340.

COMPOSITION, in *Painting*, is that great and important requiſite, the knowledge of which enables the artiſt to diſpoſe all the various objects in his picture, as required by the ſubject, and furniſhed by the imagination or invention, in ſuch a manner as to render them, individually and collectively, moſt conducive to the beauty, the effect, and the expreſſion of the whole work. The objects furniſhed by the imagination or invention, may be conſidered as ſo many unmanufactured materials, which the ſcience of compoſition teaches us to work up and diſplay, as the peculiar circumſtances of each caſe may require. Compoſition, in its general ſenſe, may, therefore, be ſtyled the ground-work of painting, upon which the ſuperſtructure, expreſſion, deſign, chiaro-ſcuro, and colouring, in a greater or leſs degree depend; and the ſcience of it opens a wide field for our conſideration, as it ſuppoſes not only the knowledge of all the various combinations or contracts of lines and forms, which are calculated to produce agreeable or ſtriking effects in general, but likewiſe, that judicious choice in their ſelection which may be moſt applicable to the diſtinguiſhing character and expreſſion of each ſubject or work in particular. Compoſition, thus contemplated, is no longer confined to the artificial pyramid or the forced contraſt, but embraces every poſſible diverſity of arrangement and diſtribution, from the artleſs ſimplicity of Giotto and Maſaccio, to the moſt ſtudied and complex grouping of Buonarotti and Rubens.

In treating this ſubject we ſhall follow the ſame method which we purſued in our inquiries reſpecting clair-obſcure and colouring. We ſhall commence by taking a curſory view of the ſtyle of the firſt reſtorers of painting, then trace the principles and ſyſtems of compoſition at different periods introduced by their ſucceſſors, and conclude by recommending ſuch examples, and ſuch precepts, as we conceive may be moſt calculated to inſure the ſtudent's improvement.

The efforts of the early artiſts, Cimabue, Giotto, and their ſchool, were entirely directed to one great point, the appropriate expreſſion of the ſtory to be repreſented; every kind of artifice was to them unknown, and their pictures may be compared to the ſimple unembelliſhed diction of the rude but faithful hiſtorian, or to the wild but uncouth ſtrains of the untutored muſe. Theſe old painters, in their ſcriptural or eccleſiaſtic repreſentations in the churches of Italy, ſeem to have conſidered the art in no other light than as a means by which to conduce to the devotion of the people, and as they really believed the truth of thoſe ſtories which they endeavoured to repreſent, (upon which perhaps a great deal depends), ſo they deſcribed every incident exactly as they ſuppoſed, or had been taught by tradition to believe, it had taken place. In their pictures of the Madonna, ſtyled in the Roman church, the Mother of God, and in their attempts to give the image of that eternal being which man never ſaw, the effect was rendered more awful and impreſſive by the introduction of choirs of angels and ſaints, in regular order, diſpoſed on each ſide and behind the throne; a more pictureſque diſtribution of figures may be found, it is true, in the large altar pictures of the more modern painters, Carlo Maratti, Luca Giordano, and others; but then ſolemnity and dignity are ſacrificed, where the Virgin Mary, with the ſaints and angels, her attendants, ſeem huddled together with as little decorum, as if a group of beggar children, at play in the ſtreet, had been the ſubject to be repreſented.

In all thoſe pictures of the old painters, which may be more particularly ſtyled devotional, we perceive an attempt to elevate the mind of the ſpectator to the contemplation of celeſtial enjoyments; in the pictures of the moderns, beginning from the death of the divine Raffaele, artifice is too apparent, and the ſubject ſeems too frequently to have been made ſubſervient to the deſire of the painter to diſplay his own academic acquirements. Nature alone ſeems to have been the preceptreſs of the old painters in compoſition, and hence that variety, and at the ſame time that ſimplicity in their works which we ſo much admire; but as they were extremely deficient in many neceſſary parts of the art, and particularly in theſe three, drawing, perſpective, and clair-obſcure, it is not ſurprizing if, in the eyes of curſory obſervers, their pictures have alone to boaſt the merit of antiquity, and that intereſt which is neceſſarily attached to the early efforts of man in every branch of ſtudy.

Inſtances, however, may be found, even in the works of the oldeſt painters, of compoſitions uniting at once propriety of expreſſion, with beauty of diſpoſition: amongſt the numerous freſcoes of Cimabue ſtill remaining in the church of St Francis, at Aſſiſi, there is in particular one, repreſenting a dead Chriſt with the Marys and other figures, where, the ſubject naturally allowing of it, the artiſt has given ſuch an agreeable form to the groups, by introducing around the recumbent figure of our Lord, the varied attitudes of figures kneeling and ſtanding, as to leave little to be deſired, ſave a greater perfection in the executive and mechanical parts of the art.

The works of Giotto, the ſcholar of Cimabue, may be ſtudied with abundant advantage as to invention and compoſition. The church of Aſſiſi, above-mentioned, poſſeſſes an extenſive ſeries of the freſcoes of this extraordinary child of nature, repreſenting ſtories of the life and miracles of St. Francis; here the compoſitions, though ever ſubſervient to the expreſſion of their ſubjects, are in ſome inſtances ſo beautifully grouped, as to leave it almoſt doubtful whether, in this reſpect, they ever were ſurpaſſed even by the beſt artiſts of later periods. One of theſe repreſents the ſtory of a nobleman of diſſolute character, who having heard of the fame of St. Francis, invited him and his companion, another friar, one day to his table. The holy converſation of the ſaint had ſuch influence on the nobleman, that he made to him a full and contrite confeſſion of his ſins, when, after receiving abſolution, he inſtantly fell down and expired. Giotto has ſeized this moment. The women, relatives of the deceaſed, the attendants, all flock, with varied expreſſions of grief, aſtoniſhment, and terror, to the corner of the picture where he lies; an elderly man, (thereby forming the connection between this group and the other) is repreſented imploring the interpoſition of St. Francis, who, riſing from his ſeat, ſeems to pity their ſorrow, at the ſame time that he endeavours to aſſuage it by the conſolatory aſſurance that the ſins of their maſter are forgiven, and that his ſpirit is in peace. The friar alone, accuſtomed to behold miracles, ſits unmoved.

In another of theſe freſcoes, Giotto has repreſented the moment, when, after the death of St. Francis, his body was carried, in the way to the place of burial, to the convent of Sta. Clara. The bearers of the body, ſurrounded by a concourſe of people, have reſted the bier on the ground: Sta. Clara is taking a laſt look at the face of him, who, in her youth, ſhe ſo much loved, one of the nuns is kiſſing the feet of the departed ſaint, a ſecond bathes his hand with her tears, whilſt others, with a gracefulneſs and tenderneſs of expreſſion not to be ſurpaſſed, are advancing from the three doors of the church to pay theſe laſt duties to the object of their affection and veneration. The church itſelf, beautifully enriched with alto-relievos, gives the moſt agreeable termination to the group.

We ſhall mention one more of this ſeries of pictures, which, though not in point of beauty equal to the two firſt deſcribed, is applicable to our preſent purpoſe as it ſtrongly exemplifies how much a proper diſpoſition of the groups in a picture contributes to the expreſſion of the ſubject. The ſtory repreſented is a miracle which took place ſome time after the death of St. Francis.

A woman from ſome cauſe or other died without making a full confeſſion; ſhe had, however, upon the whole been a good catholic, and eſpecially devoted to St. Francis; the ſaint therefore made interceſſion for her, and when the prieſt with his attendants were upon the point of carrying the body to the grave; ſhe, to the great aſtoniſhment of all preſent, ſat up, called a confeſſor who was preſent by name, revealed to him her hidden ſins, and then once more died and was buried. In the middle of the picture is repreſented the woman ſitting up on her bed, in the act of confeſſing to a friar, who at once unites in his countenance the ſtrongeſt expreſſion of terror with the moſt earneſt attention; ſome women, the friends of the deceaſed, and a child, form a group on the right; the prieſt and his attendants are on the left; both theſe groups are kept at a diſtance from the two principal figures, in the centre, by which the idea of ſecret confeſſion, a leading point in the ſtory, is more decidedly given, than could have been accompliſhed by any other manner of placing the figures. The interceſſion of St. Francis to our Saviour is repreſented in the ſky; and a little below, the effect of that interceſſion is unequivocally deſcribed, by the introduction of a celeſtial agent, who is driving before him the infernal ſpirit, by which the woman is ſuppoſed to have been poſſeſſed.

Amongſt the principal ſcholars of Giotto we may enumerate, Taddeo Gaddi, and Puccio Capanna: of the former many admirable freſcoes are ſtill exiſting in the church and ſacriſty of Sta. Croce, and in the cortile of Sta. Maria Novella at Florence, and of the latter, great part of the roof or vault, beſides two excellent compoſitions of the taking down from the croſs and the burial of Chriſt, on the ſide wall of the lower church of St. Francis at Aſſiſi.

However, the ſchool of painting founded by Cimabue and Giotto, continued with but little variation or advancement, till about 1430, when Maſaccio diſtinguiſhed himſelf by a correctneſs and perfection of imitation, hitherto unknown. He began to ſhew a juſt notion of perſpective, and firſt ſucceeded in fore-ſhortening the feet of his figures, ſo as to give them the true appearance of ſtanding on an horizontal plane; a difficulty never ſurmounted by his predeceſſors, whoſe figures, except when in profile, ſeemed generally, as if ſtanding on tip-toe. He gave a great breadth of light and ſhadow to his groups, and was an excellent colouriſt, and the heads of his figures are ſo finely drawn, ſo full of nature, and finiſhed with ſuch a delicacy and at the ſame time ſuch a mellowneſs of pencil, as to be ſcarcely ſurpaſſed by the fineſt portraits of Raffaele, Titian, or Del Sarto. In all the executive parts of the art, Maſaccio eminently excelled; but we cannot join in the opinion of thoſe who conſider him as having equally contributed to the advancement of compoſition: his aim was to make the moſt correct poſſible tranſcript of the model before him;

hence his freſcoes, in the celebrated chapel at the Carmine, abound with admirable repreſentations of his friends and cotemporaries, portraits that ſeem almoſt alive, but they are not always alive to the ſubject, nor do they expreſs by their actions or geſtures, thoſe feelings which the act of which they are repreſented as ſpectators, ſhould naturally awaken in them; in the miracle of the boy reſtored to life by St. Peter, and in the martyrdom of the ſame ſaint, the ſurrounding figures ſeem no more affected than ſo many indifferent perſons met together in the market place, to talk over the ordinary news of the day. However this work of Maſaccio greatly contributed to haſten the great æra of painting which followed, by exhibiting to contemporary and ſucceeding artiſts, a model much more perfect, at leaſt as to the executive parts of the art, than they had hitherto been accuſtomed to contemplate. Much has been ſaid as to the plagiariſms of Raffaele from this work. The Adam and Eve driven out of paradiſe in the Loggia of the Vatican, is certainly an improved tranſcript of that of Maſaccio, and the Saint Paul preaching at Athens in the cartoon, bears ſome reſemblance, it muſt be allowed, to the figure of the ſame ſaint viſiting St. Peter in priſon in Maſaccio's chapel; but if Maſaccio furniſhed the body of the ſaint, it was neceſſary that the great Raffaele ſhould animate it with the energy of his own ſoul, ere it could convey the idea of that irreſiſtible torrent of eloquence, by which the apoſtle combatted and overthrew the ſophiſms and ſuperſtitions of his audience at the Areopagus.

The immediate followers of Maſaccio were blind to his greateſt excellence, and inſtead of that mellowneſs and breadth which we find in his works, adopted a ſtyle of execution more crude and unharmonious, than even that of the more early painters; deſign, however, made a rapid advancement, which, added to a competent knowledge of perſpective, now become general, gave to Lûca Signiorelli, and others of genius, the means of embodying thoſe bold conceptions, which as yet no one had hoped to tranſmit to the canvaſs.

The chapel which Signiorelli painted in the cathedral church of Orvieto with ſtories of the End of the World, the Laſt Judgment, Paradiſe, Hell, &c. is fraught with the moſt novel and daring fore-ſhortenings, energetic expreſſions and finely contraſted groups, inſomuch that the great Michelangelo, is ſaid to have derived benefit from the ſtudy of this work, previous to his painting the celebrated Laſt Judgment in the papal chapel at Rome.

In this work, however, the compoſition, though fine in its ſeparate parts or groups, is not always judicious in the whole; that eſſential part of theory, which teaches the artiſt the policy or neceſſity of making many ſmall parts of his picture ſubordinate to the principal figure or chief group, yet remained to be known, nor was it for a long time ſufficiently underſtood, that the great diſtinguiſhing prerogative of painting, and that from which ariſes its decided advantage over every other artificial mode of repreſentation, is its power to give upon a limited plane the appearance of boundleſs ſpace. Thus, in thoſe two compartments in particular, in which the artiſt has repreſented Paradiſe and Hell; much effect is loſt by the figures and groups being ranged as it were in one line parallel to the plane of the picture; and this ſeems the more ſurprizing, as in one or two of the other compartments, and eſpecially in that deſcribing the End of the World, and the Deſtruction of the Wicked by Fire from Heaven, a moſt happy and ſtriking diſtribution of the figures into different groups, and on different planes and diſtances, is to be obſerved.

Of Domenico Ghirlandajo, the maſter of Michelangelo in his youth, it may be well to note, that although he merited, in the opinion of many, the reputation of being the beſt painter of his time, yet the ſtyle of compoſition adopted by him in his great work in the tribuna of the church of Sta. Maria Novèlla at Florence, is by no means ſuch as to rank him amongſt thoſe artiſts whoſe performances may be ſtudied with profit, as to the branch of art we are now treating of; unleſs, indeed, that the contemplation of their manifeſt faults in this particular, may tend to deter the ſtudent from purſuing a ſimilar line of conduct. The ſubject is here made ſubſervient to the rage of the painter for diſplaying his talents in portrait; theſe freſcoes containing ſtriking reſemblances of almoſt every lord, lady, or literary character of diſtinction of his time; and as the figures are throughout dreſſed in the dreſſes of the time, ſo this work is valuable, as giving perhaps the beſt idea of the coſtume of Florence towards the end of the fifteenth century, of any in exiſtence; add to this, that the whole is admirably executed; but the ſpectator may long dwell on the various beauties of this work ere he diſcovers that it is intended to repreſent the principal ſtories of the New Teſtament!

The happy æra was, however, faſt approaching, when the profound Lionardo, the great Michelangelo, and the divine Raffaele, were deſtined, not only to unite all the various excellencies of the old painters, but likewiſe, by an unparalleled and happy exertion of comprehenſive and elevated genius, at once to carry all thoſe parts of the art, which moſt ennoble it, to a height of perfection beyond which the efforts of ſucceeding artiſts have never enabled them to reach; if indeed they have ever approached it in the four great points of invention, compoſition, expreſſion, and deſign.

It was about the year 1503 that the Florentines formed the idea of decorating their great hall of council with productions of the pencil. Upon this occaſion Lionardo da Vinci executed in a cartoon the aſtoniſhing Group of Horſemen fighting for the Standard, ſo well known by the fine print of Edelink; a compoſition replete, but not crowded, and which exhibits the utmoſt energy of action, without extravagance, and the moſt ſtriking and beautiful variety of contraſt, without affectation: this was Raffaele's model for the intricate groups in his "Battle of Conſtantine," and is the great prototype of all thoſe battles and huntings ſo daringly executed by the bold pencil of Rubens. That Da Vinci at the age of fifty ſhould have ſo far ſurpaſſed the efforts of preceding painters is, however, leſs a matter of ſurprize, than, that the youthful Buonaroti, who entered the liſts with him, ſhould, as agreed by contemporary writers, have borne away the palm.

The ſubject choſen by Michelangelo for his cartoon, related to the war between the Florentines and Piſans: the moment taken was an imaginary one, when ſome of the Florentine ſoldiers, who had been bathing in the Arno, are haſtening out of the river upon the ſignal of attack, buckling on their armour, and ruſhing to the aſſiſtance of their countrymen, who had already commenced the combat in the diſtance. This ſubject naturally embraced a very great variety of character, action, and expreſſion, and was certainly moſt happily calculated for diſplaying academic acquirements, and eſpecially that knowledge of the human figure which Michelangelo is univerſally allowed to have poſſeſſed in a greater degree than any other artiſt of modern times, and which, amongſt the Florentine painters, was conſidered as at leaſt paramount to all the other parts of the art put together. It is perhaps to this laſt circumſtance that we muſt attribute the very decided pre-eminence given to the "Cartoon of Piſa" (as it was called) over that of Lionardo, and which ſoon after occaſioned his quitting his native city in diſguſt.

Conſidering theſe two celebrated works in every other reſpect, it would be a difficult taſk to determine to which belonged the preference. The figures in Da Vinci's group, it is true, were ſomewhat diſguiſed by the introduction of capricious ornaments on their armour; but, on the other hand, the Cartoon of Buonaroti wanted that breadth of chiaro-ſcuro which that of his rival poſſeſſed. Each, however, in its way, is a maſterpiece for invention, compoſition, deſign, and expreſſion; and each, in its kind, perhaps ſtill remains unrivalled. We refer the reader to a very animated deſcription of the "Cartoon of Piſa" in the third Lecture delivered by Mr. Fuſeli to the ſtudents of the Royal Academy.

The ſubjects which Lionardo and Michelangelo had ſelected for the diſplay of their talents, afforded in their nature the moſt ample ſcope for the intricacies of grouping, and the novel charms of contraſt: but it was not ſufficiently underſtood by many of the young artiſts, who flocked to ſtudy theſe works, that that which they ſo much admired, and which in reality powerfully contributed to expreſſion in the Cartoons before them, might be inadmiſſible, or at beſt ſhould be ſparingly uſed, in ſubjects of a different character. This cenſure applies not to Fra. Bartolommeo, Andrea del Sarto, and two or three others, rather cotemporaries than followers of Michelangelo; but it is certain, that the indiſcriminate introduction of contraſts, fore-ſhortenings, and naked figures, without regard to propriety or expreſſion, ſoon became a predominant characteriſtic of the Florentine ſchool.

In the ſubſequent productions of Michelangelo's pencil, we almoſt ever find the happieſt concordance of ſtyle with ſubject, nor can he be accuſed of having at any time ſacrificed the invention or expreſſion of his picture, to an oſtentatious diſplay of his powers in the executive parts of the art.

The general deſign of his ſublime works, the "Vault of the Seſtine Chapel," and the "Laſt Judgment," will be the ſubject of our conſideration, when we come to treat of invention and expreſſion in painting; we ſhall, for the preſent, content ourſelves with obſerving, that there is no part of them which affords not a valuable leſſon in compoſition. The beautiful angels, attendant on the Creator of the ſun and moon, give dignity to the ſubject at the ſame time that they enrich the compoſition. The angelic troop, ſupporting the figure of the Almighty, in the Creation of Man, by furniſhing a number of ſmall parts oppoſed to one large one, produces a delightful effect; whilſt the broad dark mantle which ſurrounds the whole, at once ſimplifies, whilſt it throws out the group; this rich group is again finely contraſted by the ſimple unembelliſhed figure of Adam. In the compartment where Adam and Eve are repreſented eating the forbidden fruit, Michelangelo has laid himſelf open to the accuſation of having been guilty of an anachroniſm, as he has introduced in the ſame picture their ſubſequent expulſion from Paradiſe; but, ere we condemn his conduct, it will be well to conſider whether the fault, if it is one, in the caſe before us, is not amply made amends for by the additional intereſt and the awful leſſon it furniſhes—here is at once the cauſe, and the effect; the tranſgreſſion and the puniſhment. This group of the "Tranſgreſſion of Man" is particularly deſerving our notice, as it furniſhes an example in compoſition different from any other in the chapel; the Eve is ſitting in a beautiful poſture on the ground, and nearly in front; ſhe extends her left arm to receive the apple preſented to her by the tempter, who is repreſented, like the Scylla of the ancients, under the form of a female terminating in a ſerpent: Adam is ſtanding immediately behind the figure of Eve; he extends both his arms to pluck the fruit off the tree, and thus diſcovers a back view of his figure from the loins upwards, thereby making a moſt beautiful contraſt to the Eve, at the ſame time that it aſſiſts, by its union or connection with the ſerpent and the tree, in forming a ſort of arch over the figure of Eve, which produces a moſt agreeable and novel effect. In that tremendous group of the "Offending Iſraelites tormented by Serpents," the low point of ſight increaſes the terror of the ſcene, at the ſame time that, by cauſing the figures to be fore-ſhortened, it permits the introduction of a greater number of them, and of a larger ſize than could have been the caſe, had the horizontal line been ſuppoſed higher. The "Prophets" and "Sybils" might each in their turn furniſh a lecture; but it would far exceed our limits to attempt to point out the various maſter pieces of compoſition with which the Seſtine Chapel abounds. Each compartment or group contains ſome principle or eſſence more or leſs diſtinguiſhing it from every other, and peculiarly adapted to the expreſſion of the ſubject it repreſents.

The "Laſt Judgment" was executed many years after the Vault of the Seſtine Chapel. With reſpect to the compoſition of this celebrated work, as a whole, there have been various opinions; ſome highly approving the uniform arrangement of the groups into diſtinct ſubdiviſions, as contributing to that awful majeſty required by the ſubject; whilſt others have regretted the abſence of that perſpective, that depth, that *ſfondo*, employed with ſo ſtriking and pictureſque an effect in the great works of Tintoretto, Paolo Veroneſe, and Rubens. The matchleſs perfection of the diſtinct groups has however remained undiſputed, and we can therefore with ſafety recommend the prints from them by Georgio Mantuanus, or thoſe recently publiſhed by Mr. Metz, as ſources from which the ſtudent will beſt acquire the principles of grand compoſition, at the ſame time that he imbibes the antidote to poverty of ſtyle, and to every thing trivial or common-place.

We have before obſerved that the older painters conſidered a certain degree of uniformity of diſpoſition as indiſpenſable in thoſe repreſentations, which were more eſpecially intended as objects of devotion or religious awe. Michelangelo, though in moſt other reſpects he departed from the ſyſtem of his predeceſſors, ſeems to have conſidered this principle as ſacred; accordingly, in his deſigns of Madonnas, Holy Families, and Pietas, we ever find this uniformity; ſometimes effected by the manner of placing the figures, and balancing equally, as it were, one ſide of the compoſition with the other; ſometimes by the regularity of the architectural decoration. His "Chriſt with the Samaritan Woman at the Well" is an inſtance of this kind, ſo is the "Flagellation at S. Pietro Montorio," and, more particularly ſo, his "Repreſentation of the Crucifixion," where the two angels in the clouds and the two figures of the Madonna and St. John, are introduced abſolutely at meaſured diſtances on each ſide of the croſs.

Fra. Bartolommeo di San Marco has practiſed a ſimilar uniformity of compoſition in his great altar pictures, and ſo has not unfrequently Raffaele, although in many of his numerous ſmall pictures of the Holy Family he ſeems to have aimed at the expreſſion of domeſtic felicity or maternal endearment, rather than to elevate the mind to the contemplation of the myſteries of redemption by a ſublime image of the Virgin Mother with the Infant God.

If the works of Michelangelo excel in ſublime imagery, or in the perſonification of ſupernatural agency, thoſe of Raffaele, on the other hand, have ever been conſidered the moſt perfect models of that ſpecies of painting which is properly termed hiſtorical or dramatic. "We ſtand with awe" ſays Mr. Fuſeli, "before M. Angelo, and tremble at the height to which he elevates us. We embrace Raffaele, and follow him wherever he leads us." The works of Raffaele never fail to exhibit the happy union of a compoſition every way adapted to the expreſſion of the ſubject, joined to an inexhauſtible variety of well-arranged and beautifully contraſted groups; and yet every part ſeems ſo naturally to grow out of the ſtory, and comes ſo home to our feelings, that the ſpectator is often almoſt tempted to exclaim, with the countryman when he ſaw Garrick, "Why I ſhould have done it ſo myſelf!"

The productions of Raffaele furniſh nothing like a recipe for compoſition. He well knew there was none, and hence thoſe forcible and diſtinct impreſſions which each of his pictures makes on the mind, and leaves indelible on the memory.

If Raffaele can be ſaid to have regulated his compoſitions by any particular rule or maxim, it was that of making each as unlike the other as poſſible, conſiſtent with propriety of expreſſion. Thus, in the Cartoon of "Chriſt giving the keys to Peter," the apoſtles, all crowding together to be witneſſes of the action, occupy the principal part of the picture, and form a group as it were in profile, the Saviour, although in the corner of the picture, being nevertheleſs rendered evidently the principal figure, by the inſulated ſituation given to him, as well as by the actions of the apoſtles, who all preſs forwards towards him, as to the centre of attraction. This Cartoon is finely contraſted by that repreſenting the death of Ananias, where the figures of the apoſtles form a group in the centre, and are all ſeen in front. The admirable deſcription of this compoſition by Mr. Fuſeli cannot but prove acceptable to the reader. "In the Cartoon of "Ananias," at the firſt glance, and even before we are made acquainted with the particulars of the ſubject, we become partakers of the ſcene. The diſpoſition is amphitheatric, the ſcenery is a ſpacious hall, the heart of the action is the centre, the wings aſſiſt, elucidate, connect it with the ends. The apoplectic figure before us is evidently the victim of a ſupernatural power inſpiring the apoſtolic figure, who, on the raiſed platform, with threatening arm pronounced, and with the word enforced his doom. The terror occaſioned by the ſudden ſtroke, is beſt expreſſed by the features of youth and middle age on each ſide of the ſufferer; it is inſtantaneous, becauſe its ſhock has not yet ſpread beyond them, and this is done not to interrupt the dignity due to the ſacred ſcene, and to ſtamp the character of devout attention of the aſſembly; what preceded and what followed is equally implied in their occupation, and the figure of a matron, entering, and abſorbed in counting money, whilſt ſhe approaches the fatal centre, and whom we may ſuppoſe to be Sapphira, the accomplice and the wife of Ananias, and the devoted partner of his fate. In this compoſition of near thirty figures, none can be pointed out as a figure of common place or mere convenience; they are linked to each other, and to the centre, by one chain; all act, and all have room to act, repoſe alternates with energy." The Cartoon of "Peter and John healing the Cripple at the Beautiful Gate of the Temple," is again ſtrikingly different from either of the others, Raffaele having there, with a boldneſs of which any but a ſublime genius would have been incapable, interſected his compoſition by the columns of the portico. But though divided, it is true, into ſeparate, and almoſt equal parts, neither the unity of action, nor the expreſſion of the picture, is impaired, whilſt the effect produced is at once novel and beautiful. In the Cartoon of "Paul preaching at Athens," the elevated ſituation, and energetic action of the apoſtle, inſtantly denote him the hero of the piece, whilſt the attentive but aſtoniſhed circle gathered round him, receive, as it were, light from him, their centre, and unequivocally declare him the reſiſtleſs organ of divine truth.

The Series of "Scripture Hiſtories," painted by Raffaele in the Loggia of the Vatican, and his other works, do not leſs evince the deſire of obtaining, as far as conſiſtent with propriety of expreſſion, this diverſity in his compoſitions; but an attentive examination of the prints from them, will better elucidate this point, and indeed every thing relative to compoſition, than a volume of prolix and laboured deſcription. In ſhort, the works of Raffaele diſplay the moſt becoming union of natural with acquired talent; ſtrength of conception, and inexhauſtible invention, with propriety of diſpoſition in the whole, and endleſs variety in the component parts.

After the death of this great maſter in 1520, the art rapidly declined, nor has any one ſince him trod with equal ſucceſs the dignified and inſtructive path of hiſtory-painting.

The great reputation of Raffaele, however, even for ſome time after his death, checked the aſcendency of miſtaken principles, at leaſt in Rome, where the great works in the Hall of Conſtantine, and other rooms of the Vatican, were ſtill continued by Giulio Romano and Raffaele's other ſcholars, after their maſter's deſigns.

Of Polidoro da Caravaggio, one of the moſt eminent, it might be ſaid that the ſoul of a Greek animated his pencil, ſo replete with Attic purity and grandeur of ſtyle are his numerous friezes on the facades of the palaces of Rome, now however beſt known by their prints by Goltzius, Cherubino, Alberti, and Bartoli.

It was not till after the noted ſackage of Rome in 1527, when the arts and artiſts were forced to ſeek an aſylum in diſtant parts of Italy, that painting was doomed to ſuffer degradation; Polidoro flew to Meſſina, Pierino del Vaga to Genoa, and Giulio Romano to Mantua, where, in the palace of the T, he explored the regions of poeſy, gave new force to the inſtructive leſſons of fable, or decked the playful charms of allegoric fiction; ſtill however firm to the principles of his great inſtructor, nor ever ſacrificing the true end of his art, the expreſſion of the ſubject, to a too oſtentatious diſplay of his prowess in the means.

We have before obſerved that Michelangelo's celebrated Cartoon of "Piſa," contributed not a little by its influence to determine the future character of the Florentine ſchool. Blind to its more ſublime excellencies, the vigour of its conception, the energy and variety of its parts, and its unity of action as a whole, the young ſtudents of Florence ignorantly imagined that a ſimilar introduction of naked and foreſhortened figures into their compoſitions, without any reference to the ſubject of their picture, would at all times inſure them the applauſe of the artiſts of their own country, and the envy of thoſe of neighbouring ſtates: nor had Michelangelo the good nature or the good ſenſe to point out their error.

An army of expert manneriſts, for the moſt part joining to a miſerable ſterility of conception the moſt audacious rapidity of execution, but proud of poſſeſſing what they thought the true ſecret of the *Grand Guſto*, now ſallied forth; nor can it be a matter of ſurprize that the palaces, the churches, and the halls of Rome, Florence, and moſt of the other cities of lower Italy, were ſo ſoon deluged with the common-place productions of mediocrity, ſince the unrelenting pencils of Giorgio Vaſari and Federigo Zuccaro alone, covered more ſquare yards of wall or canvaſs than had been effected by the honeſt diligence of perhaps any ten of their predeceſſors.

The due expreſſion of the ſubject of a picture was now the laſt conſideration. Provided two or three well drawn academy-figures, however unmeaning, occupied the foreground on the one ſide, and ſome women ſporting with their children, on the other, whilſt the centre diſplayed a pyramidical group, all was well; the employer was delighted, and the painter applauded. Thus a ſtranger may paſs and repaſs through the Sala Regia in the Vatican without being ſtruck by, or diſcovering the meaning of one of thoſe freſcoes which occupy its ſpacious walls, or without being afterwards enabled to call to mind the ſmalleſt feature diſtinguiſhing one from the other. This ſubverſion of art, this ſilly fondneſs for what was erroneouſly conſidered pictureſque compoſition, for near a century afterwards degraded the ſchools of Rome and Florence; we ſhall therefore leave them, and turn the reader's attention to thoſe of Lombardy and Venice.

If the anatomic ſtudies of the old Florentine artiſts had rendered them almoſt excluſively the maſters of correct deſign, the painters of Lombardy could boaſt a more complete inſight into the doctrine of perſpective, and were certainly the firſt who applied it with real effect in large works.

Melozzo da Forli, in the middle of the fifteenth century, in his freſco in the vault in the tribuna of the church of St. Apoſtoli at Rome, firſt diſcovered what the Italians call the knowledge of the *Sotto in Sù*, that is, the method of foreſhortening figures, ſo as to give them the due appearance of rotundity and projection when ſeen from below; and upon the ſame principle, Andrea Mantegna, in ſeveral of his great works, and particularly in a chapel at Padua, where the ſtoried compartments are entirely above the eye, adopted, with equal boldneſs and effect, an ideal point of ſight upon a line with the eye of the ſpectator, that is beneath the very bottom of the picture.

From ſources like theſe, Antonio Allegri da Coreggio, the ſplendid meteor of the Lombard ſchool, imbibed the firſt principles of his art. With a ſpirit every way conformable to his name, he pictured the "Joyful Aſſumption of the Madonna amidſt Myriads of the Angelic Hoſt," in the cupola of the duomo of Parma, and the "Aſcenſion of Chriſt," in the church of S. Giovanni in the ſame city; works which may be juſtly ſtyled the never-equalled models for that ſpecies of compoſition. In the execution of theſe, and probably of his other chief works, he was however greatly aſſiſted by his friend Antonio Begarelli, a celebrated Modeneſe ſculptor, who modelled for him in clay all the figures, ſo that Coreggio, by placing and grouping them together as they were to be repreſented, was enabled to delineate, with the greateſt correctneſs, every foreſhortening, and at the ſame time to acquire a truth and boldneſs of light and ſhade unattainable by any other means. And here it may be well to obſerve, that the trouble of preparing ſuch models in the firſt inſtance, is amply repaid by the great facility, or rather certainty, which it gives the artiſt in the execution of his work. Moreover, the painter having his modelled figures before him, and being enabled, by varying the ſituation of his eye, to view them in every direction, will frequently diſcover beautiful combinations which he never dreamed of, at the ſame time that he is rendered leſs liable to the error of too often repeating the ſame view of a figure, or the ſame action, and is taught to avoid a common-place mode of compoſition.

Primaticcio, a native of Bologna, in his commerce with Giulio Romano, whom he aſſiſted in his works at Mantua, acquired an admirable talent for treating poetical ſubjects. Maſter of perſpective, and the *Sotto in Sù*, his beautiful fictions on the ceilings, and other compartments, in the palace of Fontainbleau, alike charmed by the fire with which they were conceived, the elegance of their compoſition, the prodigious boldneſs and truth of their effect, and the eaſy grace with which they were executed.

The grandeur and ſtriking appearance of projection and depth, for which the works of Primaticcio were ſo remarkable, judging as well by their prints as by the writings of thoſe who witneſſed them prior to their deſtruction, was in a great meaſure occaſioned by his having univerſally choſen, what is called in perſpective a *ſhort point of diſtance;* by which mode of conduct the figures in his near-ground appeared proportionally large, as thoſe behind diminiſhed in a more rapid gradation. This mode of conduct in Primaticcio is the more worthy of remark, as it is the reverſe of what we generally find adopted in the works of the great Roman and Florentine painters, his predeceſſors. It became, however, a favourite doctrine of the Venetian ſchool, particularly of Tintoretto and Paulo Veroneſe, and was one of the leading principles of the Caracci in the formation of their ſtyle.

The compoſition of Giorgione, Titian, and the older Venetian painters, is ſimple and dignified, ſuggeſted by the ſubject alone, and of courſe liable to none of thoſe objections which apply to the works of their followers, Tintoretto, Paulo Veroneſe, Palma, and a multitude of others, who, like the Florentines, valuing themſelves chiefly upon the poſſeſſion of only a part of the art, ſacrificed to their favourite darling all the remainder. No longer expreſſion, but colouring and glitter of effect became their object, and hence, with all their prodigious talents, they ſoon turned the art into a ſplendid toy.

The works of theſe great maſters (for great they were in ſpite of all their faults) may nevertheleſs be ſtudied with benefit, even as to compoſition, as they at all times poſſeſs a boldneſs and variety of diſpoſition, which rank them far above the inſipid and mannered performances of their cotemporaries of Florence and Rome.

About the end of the 16th century, the Caracci of Bologna attempted, by an union of the ſcattered excellencies of the various ſchools beforementioned, to eſtabliſh a perfect ſyſtem of art: but though they indeed ſo far ſucceeded as to form a ſtyle in which no particular fault ſeemed to predominate, ſtill in no one point did they fully reach the purpoſed objects of their emulation. Their works preſent neither the dignified compoſition, the juſt and ſtriking expreſſion, the beautiful variety of character, which diſtinguiſhes thoſe of Raffaele; the ſublime conception, or the learned and grand deſign of Buonaroti; the grace and enchanting effect of Coreggio, nor the truth and richneſs of Venetian colour; but ſeem rather the reſult of a ſyſtem founded on the baſis of a compromiſe between the eye and the underſtanding, the mechanic and the ideal of the art; in forming which compact, however, the former have been evidently allowed the preponderance. This remark is, perhaps, leſs applicable to the productions of Ludovico Caracci; but with reſpect to the chief works of Annibale, and particularly his Farneſe gallery, we cannot withold our aſſent to the critiques of Mr. Fuſeli, and the ſevere but juſt remarks of Mr. Webbe.

Having ſaid thus much, it cannot be expected that we ſhould hold forth the Caracci as models for imitation; there is nevertheleſs a breadth, a concordance of the various mechanical parts of the art, and an eaſe in their ſtyle which render it highly deſerving our regard, and would have juſtly entitled the Caracci to a reputation even greater than that which they have ſo long enjoyed, had their prodigious powers been made the vehicle of more elevated conception.

With reſpect to the ſcholars of the Caracci, and other artiſts of reputation, who immediately ſucceeded this epoch, it is only to our preſent purpoſe to obſerve, that grace and beauty rather than grandeur or ſublimity, ſeem to have been their objects, and that whatever eminence they ſometimes attained in their Holy Families and devotional ſubjects, ſtill the dignity of hiſtorical painting was evidently on the decline.

Niccolo Pouſſin alone ſeems to have conſidered the art as a language addreſſed to the mind through the organs of viſion. Poſſeſſed of a refined and ſcrutinizing mind, he at all times collected, and, with the greateſt ingenuity, inſerted in his pictures all thoſe collateral circumſtances, probable or poſſible, which his ſubject could furniſh; and hence his works, more addreſſed to the imagination than the eye, at once invite and are ſure to reward inveſtigation. The greateſt defect, however, of his compoſitions, ſeems to be that theſe explanatory or acceſſorial groups generally appear too principal, and thereby not unfrequently counteract their object, by diſtracting the attention from the principal figure or group, deſtroying the unity of action, and weakening that expreſſion which they were intended to augment. Were we to draw a compariſon between Pouſſin and Raffaele, we ſhould liken the former to the cool but ſubtle reaſoner, who by ſlow degrees brings us to grant his poſition; Raffaele to the heaven-taught genius who at once darts the ray of truth upon our minds.

The works of Pouſſin, though eſteemed even in his lifetime, had little influence in correcting the corrupt and meretricious taſte which was every day gaining ground in Italy. The proper end of the art had been long forgotten or habitually ſacrificed, and that bane of painting, pictureſque, or artificial compoſition, which, however varying in its mode, was ever the ſame in its effect, became every day more deeply rooted.

Poverty of conception, or rather no conception at all, common-place or unmeaning attitude, contraſt ſo often repeated as entirely to loſe its effect, and, above all, empty buſtle, were now become the elements of what was ſtill called hiſtorical compoſition: if to this we add a brilliant rapidity of execution, joined to gay colouring and tolerable light and ſhade, with occaſionally a madonna's or an angel's head, rather pretty and ſeductive than devout, we have the ſum total of the merits of the moſt eminent artiſts who ſucceeded this period, and the genuine characteriſtics of the admired Pietro da Cortona, the facile Luca Giordano, and the inſipid Carlo Maratti.

It would ſwell this article beyond our preſcribed limits, without throwing much additional light on our ſubject, were we to attempt to trace the different changes of ſtyle which at various periods took place in the ſchools of painting of Germany, Flanders, Holland, or France. The ſucceſſion of young ſtudents, who at all times conſidered a viſit to Italy as an indiſpenſable part of their education; naturally imbibed in a greater or leſs degree the principles of thoſe to whom they had been taught to look up as models for their imitation: hence the ſtyle of the Florentine and Roman manneriſts of the 16th century, unjuſtly denominated the followers of Michelangelo, was caricatured in the prepoſterous works of Martin Heemſkerck, Van Mander, Spranger, and Goltzius; that of Tintoretto feebly imitated in thoſe of his ſcholars, de Vos and Rotthenhamer. Rubens, however, who, though long in Italy, became no wiſe infected by that poverty of ſtyle which then prevailed, broke the fetters of corrupt ſyſtem, and reſcued his countrymen from the effects of ſuch baneful influence. His comprehenſive genius, cultured by reading, enlightened by travel, and bleſt, above all, with that envied quality, a juſt appreciation of its own powers, could not but obtain its object, that object being once clearly defined and ſteadily purſued. What that object was, the decided character of his works ſufficiently determines: it was unqueſtionably the union of magnificent and expreſſive compoſition, with the moſt ſplendid colouring and the greateſt breadth of chiaro-ſcuro; for, however enchanted by the ſpells of colour, Rubens never forgot that painting is mute poeſy, and its firſt great prerogative, the converſe, which, through the medium of the eyes, it is permitted to hold with the underſtanding. It cannot, therefore, be ſaid of Rubens, as of the Venetian painters we have cenſured, that he ſacrificed the ideal to the mechanical part of his art. With the exception of his ſmaller works, or ſuch as he was ſometimes neceſſitated to undertake, in compliance with the will of his employers, we generally find in his productions the moſt judicious application, the moſt happy combination of his powers:—Subjects allowing full ſcope to the exuberance of his invention, compoſitions furniſhing an ample field for the magic blaze of his tints, and the broad expanſe of his maſſes.

It was the good fortune of Rubens that the burines of the moſt eminent engravers were employed under his own inſpection, to make prints from all his chief works; and indeed ſo admirably is the character of the originals preſerved in thoſe of Bolſwort, Voſterman, Pontius, and others, that when the pictures ſhall be no more, they alone will be ſufficient to eternize the claims of this great maſter of the Flemiſh ſchool. As an inventor and compoſer, the "Battle of the Amazons," the numerous "Huntings of Wild Beaſts," the "Raiſing of the Croſs," the "Michael combating the Devil and his Angels," and the two tremenduous repreſentations of the "Fall of the Wicked," are alone ſufficient to place Rubens in the firſt rank; to ſay nothing of his celebrated "Garden of Love," and the truly poetic allegories in the "Luxemburgh gallery."

Of Rembrant, the great head of the Dutch ſchool, it has been juſtly remarked by Mr. Fuſeli, that he was "a genius of the firſt claſs, in whatever relates not to form." We have in another place ſpoken of his chiaro-ſcuro, (ſee Clair *Obſcure*,) and we can, with equal propriety, upon the preſent occaſion, recommend the ſtudy of his works to all thoſe who feel with us, that the telling of the ſtory, and the appropriate expreſſion of the ſubject are the true ends of compoſition; nor will we omit to add, that the works of many of the other Dutch painters, particularly Oſtade and Brawer, however the humble repreſentations of low and vulgar nature be their object, abound in admirable examples of compoſition, and may be ſtudied with advantage, even by ſuch as make the more noble path of hiſtorical or epic painting the courſe of their purſuit.

In the retroſpect we have taken of the ſtyles of compoſition at different periods, adopted by the ſchools of Italy, it has been our care to point out to the ſtudent ſuch examples as are beſt calculated by their influence to promote his advancement towards the legitimate end of our art; at the ſame time, that we have cautioned him againſt that corrupt but ſpecious ſyſtem of grouping, which, for diſtinction's ſake, we have called pictureſque.

The art of painting is a language addreſſed, through the medium of the eyes, to the underſtanding; like that addreſſed to our minds through the ears, it muſt have ſome ideas, ſome truths to communicate; and the perfection of painting, as well as of writing, conſiſts in conveying thoſe truths to the mind in the moſt clear, the moſt forcible, and moſt beautiful manner. A judicious diſtribution of the arguments in a diſcourſe is of importance, inaſmuch as it gives additional force, and ſheds increaſed luſtre on the evidence contained; but in a picture this propriety of diſtribution is itſelf the argument and the evidence, and is therefore indiſpenſable.

Thoſe who are converſant with the firſt ſketches and drawings of great maſters, know that a few ſimple rude lines are frequently found ſufficient to impreſs the mind with a deciſive and immediate idea of the ſtory meant to be repreſented, and that, in many caſes, even the expreſſions as well as the actions of the chief figures ſeem evident, although no features of the countenances be delineated.

We may, therefore, ſafely affirm, that any rule, any mode of compoſition, except ſuch as is dictated by the ſubject of a picture, is wrong, and that, were this doctrine ſufficiently underſtood, we ſhould not ſo frequently paſs unmoved by graphic repreſentations, or remain ignorant of the ſubjects they were intended to expreſs.

To attempt, therefore, to preſcribe any general method of diſtribution would be to inſult the underſtanding of our readers and to degrade the art. The painter, warmed by his ſubject, muſt form the ideal picture in his imagination, and from thence transfer it to the canvaſs: it is only as to the relative economy of the parts of the work that ſome hints may be ſuggeſted: theſe are the reſult of obſervation and experience, and bear the ſtricteſt analogy to the precepts we have inculcated reſpecting clair-obſcure and colouring, and, perhaps, to every other part of the art.

As there ſhould be in a picture one principal maſs of light, which, however connected with others, ſhould ſtill predominate; ſo one group or one figure ſhould ſtrike the eye with the ſame ſuperiority over the ſecondary groups or figures of the compoſition; as in clair-obſcure there is no rule by which we are obliged to place the principal light in any one given part of the picture; ſo are we at liberty to give to the chief group or figure of the compoſition that ſituation which we judge moſt appropriate. As in clair-obſcure, an inequality of parts, a ſubordination of ſeveral ſmall maſſes to one large one, never fails to produce richneſs and beauty of effect; ſo in compoſition a ſimilar richneſs and beauty are the reſult of an oppoſition of ſeveral ſmall bodies or parts, to one large and ſimple; as we have before illuſtrated by the ſublime group of the Almighty, ſupported by a multitude of angels, in the "Creation of Adam," by Michelangelo.

As by the addition of ſmaller maſſes of light, connected with the principal maſs, that maſs acquires at once greater breadth and influence; ſo the unity of action in a compoſition is in moſt caſes powerfully augmented by a repetition of nearly the ſame action in two or three of the acceſſorial figures arranged together, one nevertheleſs being principal: this was the frequent cuſtom of Raffaele, has its foundation in nature, where ſimilar ſentiments moſt frequently excite ſimilar outward demonſtrations, and never fails, if judiciouſly managed, to produce its effect.

Every thing that has been ſaid relative to contraſt of clair-obſcure, or relieving dark or light maſſes immediately by their oppoſites, equally applies to compoſition, where ſtrong contraſts of line, of back to front figures, &c. produce ſimilarly ſtriking and beautiful effects, and muſt to inſure thoſe effects be uſed with ſimilar diſcretion and parſimony. The too frequent introduction of contraſts of lights and ſhadows or of colours, produces a ſpotty and confuſed effect; the inordinate uſe of contraſts in compoſition produces ſimilar confuſion, and defeats their end. The moderate introduction of them in both caſes gives a zeſt to the picture. It is like the border or other well-diſpoſed ornament on a piece of drapery; but when indiſcriminately uſed, the work reſembles the rich gothic medley of an embroidered petticoat, where the beautiful folds of the ſtuff are wholly obſcured by tinſel and gewgaw.

Having obſerved thus much, we muſt refer the reader, who is deſirous of obtaining a more complete inſight into the ſubject of this inquiry, to the works of the great maſters above-mentioned, or to the numerous prints which have been made from them, by the moſt eminent engravers of the laſt three centuries. One hour ſpent in the ſtudy of the Cartoons of Raffaele, or the Laſt Judgment of Michelangelo, will perhaps teach more than could be inculcated by words in the compaſs of this volume.

What we have ſaid of hiſtorical compoſition may equally apply to landſcape; each work ſhould poſſeſs a decided character, diſtinguiſhing it from its neighbour, and calculated to incite a train of kindred reflections. This we ſometimes find in the ſimple views of the Flemiſh and Dutch painters, who painted nature as they found her, and did not think it neceſſary that every picture ſhould poſſeſs a given proportion of fore ground, middle ground, diſtance and extreme diſtance, a winding road, a meandering ſtream, a water mill, a church ſteeple, a hanging wood, and a mountain.

The works of the two Pouſſins, ſome of thoſe of Salvator Roſa, Dominichino, and the Caracci, and the admirable etchings from the drawings of Titian, abound in the fineſt examples of ſublime and characteriſtic landſcape, and are indeed ſo perfect in their way, that they can never be ſufficiently contemplated by the artiſt who would attain eminence in this delightful branch of art.

Plates illuſtrative of compoſition.

No. 1. "The Battle of the Standard," by Lionardo da Vinci.

2. "The Cartoon of Piſa" (or according to Vaſari, its chief group) by Michelangelo Buonaroti.

3. "The Creation of Man," the "Tranſgreſſion at the Tree of Knowledge," and "The Expulſion from Paradiſe;" freſcoes of Michelangelo in the Seſtine chapel.

4. "Groups of the Laſt Judgment," by the ſame author in the ſame chapel.

5. "Paul preaching at Athens" from the Cartoon, by Raffaele, at Hampton Court.

6. "The Group of the Aſſumption of the Madonna," in the cupola of the Duomo at Parma. Coreggio.

COMPOSITION, in *Pharmacy*, the art, or act, of mixing divers ingredients together into a medicine; ſo that they may aſſiſt each other's virtues, ſupply each other's defects, or correct any ill qualities thereof.

COMPOSITION, in *Printing*, ordinarily called *compoſing*, is the arranging of ſeveral types or letters in the compoſing-ſtick, in order to form a line; and of ſeveral lines ranged in order in the galley, to make a page; and of ſeveral of thoſe to make a form.

The compoſing-ſtick is made of iron generally, ſometimes braſs or wood; of greater or leſs length or depth, according to the page to be compoſed, or the compoſitor's fancy: it hath two ſliding pieces, to be faſtened by means of a nut and ſcrew, which are ſlipped forwards or backwards, at the pleaſure of the compoſitor, and according to the ſpace which the lines, notes, &c. are to take up. See *Plate Miſcellany, Fig.* 5.

The compoſing-ſtick ordinarily contains ſeven or eight lines of a middle-ſized letter; theſe, when ſet, are taken out, by help of a thin ſlip of braſs, termed a rule, and diſpoſed in the galley; and others compoſed, till a page be formed. The page being compoſed, is tied up, and ſet by; and the reſt of the pages of the ſheet prepared in the ſame manner: when done, they are carried to the impoſing or correcting-ſtone; there ranged in order, and diſpoſed in a chaſe, or iron-frame, fitted with wooden furniture; then, the quoins being ſtruck in, it is carried to the preſs to be printed.

Composition, in *Sculpture*, from *Compozitione*, Italian, the art of placing figures or other objects together, whether by entwining them in groups, or forming them into maſſes more nearly or diſtantly appoſed. The word bears the ſame meaning in the arts of deſign as in literature, from which it was moſt probably received, with many other terms, by the Italian artiſts at the revival of learning. Although in its moſt ſimple ſenſe it is only ſyntheſis, or joining together; yet, in its extended acceptation, it comprehends the production, order, and fitneſs of all the parts contained in the whole. The firſt elements, therefore, are invention and ſentiment; the invention ſhould be new and copious, affording an abundant choice of beautiful parts according to the ſubject, whether there be many figures or one only; the ſentiment muſt be juſt and ſtriking; according to the rule "feel yourſelf if you would make others feel;" this muſt pervade every part of the character of the figures; their action or paſſion expreſſed to the points of their fingers and toes as well as in the very folds of their drapery.

The order of compoſition contains the divine, heroic, and hiſtoric. The divine contains all ſublime and terrific ſubjects of divinities, angels, departed ſouls, and infernal miniſters. The heroic, according to the ancients, conſiſts of thoſe mortals, ſaid to have one mortal and one immortal parent. The hiſtoric claſs contains the whole ſeries of human life, in which however the moſt exalted perſons and circumſtances are always to be preferred.

The arrangement muſt be dramatic, repreſenting an action; becauſe ſentiment only affects the countenance of the figure prior to action, and words cannot be expreſſed by mute figures; therefore the ſentiments and paſſions muſt be demonſtrated by the action, in which the figures partake. The principal perſon muſt have the moſt diſtinguiſhed place, whilſt the inferiors occupy ſubordinate gradations; thus in "Prometheus chained;" Prometheus occupies the firſt intereſt and place, whilſt Force, Strength, and Vulcan are gradually inferior, although linked in the ſame group. If the hero or heroine of the ſubject be not entwined in the ſame group with other figures, he or ſhe will ſtill be diſtinguiſhed by a preferable ſituation to thoſe in which the inferior perſons are placed; this rule is obſerved in all the beſt pictures of the Herculaneum collection. In the antique baſſo-relievos and painted vaſes, and in the beſt works of antiquity, we ſcarcely ever ſee more figures introduced than ſuch as are ſufficient to tell the ſtory, and for this reaſon that the expreſſion may be the ſtronger, being leſs divided.

Outline. The general outlines of a compoſition, whether it conſiſt of one or more groups, ſhould be agreeable to the eye, which is produced by a ſucceſſion of curves of different ſegments alternately reverſed; or, in other words, a ſucceſſion of S. lines of different curvatures and dimenſions. Theſe will be more gentle in tender and graceful ſubjects, ſuch as the Triumphs of Nymphs, Naiads, and Sea Divinities, the Judgment of Paris, &c. In the antique baſſo-relievos, theſe curves become more violent with a mixture of angles in ſubjects of great exertion, ſuch as the War of the Giants, the Battles of the Lapithæ and Centaurs, the Athenians and Perſians. See Stuart's Athens, vol. iii. Muſeum Pium Clementinum. Baſſo-relievos. In the fine antique groups, as the Laocoon, Niobe and her Daughter, Cupid and Pſyche, and the Fauns and Nymphs, the lines are incatenated (chained) as it were linked into each other in whatever view they are ſeen.

Light and Shadow. Sculpture is not like painting, ſeen and forced on our perception, by the variety and brilliance of its colours. On the contrary, it has properly no colour at all; and its forms are underſtood by the effect of light and its privation, with the degrees of their medium called middle tint; theſe, in fact, produce the all of ſculptural forms to the eye, becauſe no ſuch thing as outline really exiſts, and when we ſpeak of it or uſe it, it is only to demonſtrate form geometrically. Light and ſhadow will be continually varied in the varied forms of the human figure. If ſeen abroad in the open air, or illumined from a ſky-light within doors, the light will ſtrike moſt powerfully on the head and breaſt, and gradually with leſs force on the lower part of the body and inferior limbs as they approach nearer to the earth. If the figure be recumbent, or in an horizontal poſition, thoſe parts will have moſt light which are neareſt to the luminary. If the figure be inverted, the bottoms of the feet will have the ſtrongeſt lights, which will gradually diminiſh as they approach the head; and conſequently all thoſe parts which are ſhadowed, when the figure is upright, will be lightened in this poſition, and *vice verſâ.* It muſt be remembered that, as the human figure partakes of globular forms, ſome one part will be lighter than the reſt, and that light will be brighteſt in one point. It will be found that figures in ſculpture are almoſt covered with middle tint, having a ſmall portion of bright light neareſt the luminary, with a very few dark and ſtrong ſhadows which relieve particular projections. Baſſo-relievos preſent the general effect of darkiſh figures on light back-grounds; in diſtribution of quantity, of both lines and form, that will be moſt agreeable which is inherent in the nature of things, which pervades all creation, and is more particularly evident in muſical proportion of 3ds, 5ths, and 8ths, with their ſubdiviſions and relative quantities.

We muſt however obſerve, that the rules for compoſition, like all other rules laid down for liberal art, will only aſſiſt genius; they will never produce any thing without the vigorous exertion of mental powers and manual induſtry in the ſubtle inveſtigation and diligent imitation of nature; all muſt be done by ſympathy and beautiful repreſentation; rules may be compared to the ſcaffold for raiſing a building. We muſt therefore remember that the beauties of nature are alſo various as they are endleſs, and from them only we can furniſh ourſelves with original materials for compoſition, by continually obſerving the expreſſion of ſentiment and paſſion in men, women, and children; the characters of their faces, the forms and action of their limbs, their draperies, and the manner in which the direction of the folds obſcures or indicates the bodies or limbs, in the grouping of figures; the entwining of the limbs ſhould be carefully obſerved, and the planes in which the different parts of the bodies and limbs are directed.

In the liberal arts, the ſentiment of a compoſition applies to our ſympathetic feelings, as the invention ſurprizes and delights by its novelty, and both together animate the maſs as a body is animated by the ſoul; and as no compoſition would be complete or intereſting without them, ſo when theſe vital principles are obtained, great care ſhould be taken to confine their demonſtrative forms within that department of art to which they belong, in order that the whole may be as pleaſing as intereſting, without deformity or abſurdity. Thus, for example, all thoſe poſitions which extend the human figure by violent action ſhould in baſſo-relievo be repreſented in the flatteſt view, in which all the lines of the body and limbs may be underſtood in the fulleſt and cleareſt manner, without legs or arms ſtanding out horizontally from the back ground, like ſcaffold poles driven into a wall. Such extended members belong only to the claſs of entire ſculpture, as ſtatues and groups. The lines and limbs in the compoſition muſt be more parallel to the back ground, as the alto-relievo or baſſo-relievo recedes from entire ſculpture, until, in the flatteſt relief, the moſt complicated forms and groups are diſtinguiſhed by little more projection than an outline gives.

COMPOSSIBLES, Compossibilia, in *Logic,* ſuch things as are compatible, or capable of ſubſiſting together.

COMPOST, in *Agriculture,* a term ſignifying that ſort of manure which is formed by the mixture or combination of one or more different ingredients with dung or other ſimilar matter, ſo as to conſtitute an uniform maſs or ſubſtance fit for the improvement of the ſoil.

Theſe compoſts are uſually made by mixing various ſubſtances with ſtable or yard dung; and hence, in ſome counties, are called *mixens.*

The moſt common materials for this purpoſe are turf pared from waſte places, virgin earth, peat earth, lime, the ſcourings of brooks, ponds, and ditches, weeds, ſea-ſand, rubbiſh of buildings, coal-aſhes, &c. That dung alone, properly managed and applied, is a moſt valuable manure, is beyond all doubt, but it is certainly not equally uſeful in all ſoils and ſituations. It is much better calculated for active than inactive ſoils. On lime-ſtone, chalk, &c. it meets with abundance of active materials; but upon clays, deep loams, &c. it operates beſt in conjunction with lime or ſome other ſtimulating ſubſtance. When dung is intended for a compoſt, no attempts ſhould be made to add a large quantity of lime, earth, &c. till it is properly fermented, every addition of this checking the fermentation. The lime, earth, &c. ſhould be added after the fermentation is finiſhed, and the whole then carefully mixed, and laid up together. In a few days a ſecond fermentation will come on; and if the mixture has been properly turned over and properly incorporated, it will be fit for uſe in a month or ſix weeks. Some judgment and attention will be requiſite, with regard to the quantity of lime and other active principles employed; for, if the quantity be ſmall, their action upon the rich ſubſtances in the dung will be partial and imperfect; and if too great, a conſiderable loſs may be ſuſtained by their over action. If the quantity of earth alſo be ſuch as to preſs the dung too hard, the air will be excluded, and the ſecond fermentation be impeded or prevented. It is certainly a right method to lay a good coat of earth as a foundation for the dunghill, into which the moiſture of the dung may reak down; and it is no bad way to make a heap of ſuch ſubſtances as can be readily obtained, apart from the dung, and to throw the moiſture of the dunghill, and the urine of cattle over it frequently.

The compoſts employed by the farmer are formed in various ways. In ſome places where there is a head or foot ridge, too high to admit the water being readily diſcharged from the field, they plough it, then fill it full of lime, dung, or both, and, after frequent ploughings, ſpread it upon the field. After the lime by theſe means is ſufficiently mixed, the earth may be gathered into a heap with the ſpade, and mixed with dung; or the whole operation may be performed with the ſpade, which is ſtill better.

It is remarked by Mr. Young, that "the farmer may have great advantage from compoſts; which, when they conſiſt of proper materials, and are ſkilfully mixed, he may ſafely depend upon. Where a variety of materials can be had, they may, he ſays, be laid as follows: firſt clay or ſtrong earth, next ſoap-aſhes, dung, loamy earth, lime, tanners' bark, green vegetables before they run to ſeed, earth, or as many of theſe as can be got; alſo fat chalk, ſea-weeds, ſea-ſand, and ſeveral others; which may be ſo mixed, as not only to raiſe a general fermentation throughout the whole compoſt; but likewiſe to ſuit the nature of the land on which it is intended to be laid. The common way is to lay the ſeveral materials in layers, one over the other, till a large heap is raiſed; and it is adviſed by ſome authors, and the practice of many farmers is, to make theſe layers from ſix inches to a foot in thickneſs; but this he has found by experience is wrong. For the fermentation raiſed in the compoſt is not ſtrong enough to penetrate theſe thick layers, eſpecially thoſe of clay, or ſtrong earth; for after the reſt have ſufficiently fermented, and the compoſt is turned, theſe layers riſe almoſt as whole as when firſt laid, and muſt be broken by hand, to mix them with the reſt of the compoſt; whence ariſe two inconveniences, one an extraordinary expence, and the other that twice or thrice turning is ſometimes neceſſary to diſſolve theſe large pieces; and as a new fermentation is excited every time the compoſt is turned, the ſtrength of the manure is greatly waſted before it is laid upon the land, where it is then incapable of raiſing any conſiderable fermentation, which is, he thinks, one of the principal uſes of manure."

It has been ſuggeſted, that the beſt way of making compoſt is not in thick layers; but after the ground is marked out for the compoſt, to lay the ſeveral materials, after being well broken, in heaps round the ſpace marked out for the compoſt heap; and to place a man between each two heaps, to throw the manure ſpreading upon that ſpace. In this manner, the compoſt heap will ſoon be raiſed to the intended height, and the ſeveral ſorts of manure being thus well mixed, the whole will ſoon begin to ferment, and will incorporate as fully in two months, as the ſame manures, placed in layers in the uſual way, will in four or five. The owner, therefore, in making ſuch compoſts, ſhould not prepare them too long before they are laid upon the land; otherwiſe they will be much waſted, and their beſt parts evaporated and deſtroyed. And "compoſts prepared in this manner need not be turned, or at moſt not above twice. If the fermentation is obſerved to abate too ſoon, holes ſhould be made with a pole from the top almoſt to the bottom of the heap, upon which throw urine, or the returning of a dunghill, which will fill the holes, force through the whole ſubſtance of compoſt, and ſoon complete the fermentation." It is added, that "ſuch a compoſt, by duly proportioning the ingredients, may be made to ſuit any ſort of land, and is excellent for meadow or paſture grounds. A way to improve theſe, is to cut them five or ſix inches deep with the five-coultered cutting plough, or ſcarificator, which cuts the ſurface in ſlips four or five inchs aſunder, but does not raiſe or turn them. This cutting of the roots of the graſs, and the manure laid on at the ſame time, ſinking into theſe inciſions made by the coulter, cauſe an improvement in the quality of the herbage, and alſo make ſuch graſs grounds produce much more than they did before. But here it is to be noted, that cutting the ground firſt, and then laying on the manure, makes a greater improvement than manuring firſt, and then cutting; and both are ſuperior to manuring and not cutting; all which have been proved by experiments. The cutting-plough is uſed with ſucceſs upon clay grounds, loams, and gravel; but in very ſtrong grounds, the coulters are apt to be thrown out of their work by ſtones; and therefore, it is not proper to uſe the cutting-plough where ſtones abound to any great degree."

It is added, that "in ſuch compoſts, where it is intended to uſe a large proportion of earth, that lies at a conſiderable diſtance from the limeſtead, to ſave the double carriage of it to and from the compoſt heap, the dung and other materials may be carried to a head land of the field to be manured, and be there mixed into a compoſt."

It is contended that "the beſt ſituation for a compoſt, is upon level ground; or if made upon a deſcent, a trench ſhould be cut on the lower ſide to receive the running of the heap, which is ſome of the beſt part of it, and ſhould from time to time be thrown up again, which will quicken the fermentation."

It is ſuppoſed that "the richeſt compoſts may be made in the farm-yard, which ſhould be made deepening all round from the ſides to the middle in form of a hollow ditch or baſon. When the yard is made in this form, little of the urine or liquid part of the manure can run off or be waſted. When the dung is carried from the ſtables, cow-houſes, &c. into the farm-yard, it ſhould not be thrown careleſsly in heaps, each ſort by itſelf, but carried in carts or wheelbarrows, and laid regularly, and ſpread all over the yard. Upon this ſhould be ſpread a thin layer of earth, mud, the ſcowerings of ditches and ponds, green vegetables before they run to ſeed, and other ſuch materials as are moſt ſuitable to the nature of the land, to be manured with them. The racks and cribs out of which the cattle are foddered, ſhould be frequently moved over the yard, that the offal ſtraw and hay may be equally diſperſed, and trod in by the cattle. This method of ſpreading the dung and other materials being continued, the whole will be incorporated with the urine of the cattle, and make an extraordinary rich compoſt." It is ſuppoſed that the only inconveniency of this kind of compoſt, is its being filled with the ſeeds of weeds, from the earth mixed with it, the hay, ſtraw, and dung of the cattle. It is, therefore, a manure beſt ſuited to graſs-grounds, and to ſuch arable lands as are to be hoed, as turnips, cabbages, carrots, potatoes, beans, &c. as theſe weeds will in a great meaſure be deſtroyed by good hoeing," or a proper attention to the after culture of the crops. And the earth or mud gathered from the bottom of ditches is excellent for compoſts. It is uſually the lighteſt part of the ſoil, carried thither by water, and frequently contains a large proportion of vegetable matter. To this may be added, the cleanings of roads, eſpecially where they are laid with limeſtone. But one of the beſt materials for compoſts is peat-earth: this fills up the pores of a ſandy or gravelly ſoil, without diminiſhing its friability. Even where applied by itſelf to ſuch ſoil, peat increaſes its fertility. But in a hard clay ſoil, it ſhould be fermented with lime or dung, or both, and frequently turned, to make it mix properly. Without this precaution it dries, hardens, and cannot be afterwards properly mixed and incorporated with the ſoil. With regard to the making of compoſts, if only one ſort of manure be uſed, it is only neceſſary to put the manure and earth into alternate layers, in a long ridge, and top it ſo that the rain may not waſh through it. When both lime and dung are uſed, a layer of earth ſhould be interpoſed between every two beds of lime and dung; for lime, if mixed with dung in the firſt ſtage of its putrefaction, corrodes and diſſipates its effluvia. After the firſt fermentation of the dung is completed, the whole ſhould be turned, to mix the ingredients; and this operation ſhould be repeated until the maſs be ſufficiently pulverized; which is done by cutting the compoſt with a ſpade in perpendicular ſlices. All the weeds ſhould be collected from the neighbouring fields, before they run to ſeed, and mixed with the compoſt. The weeds alſo that grow upon it ſhould be buried down in it. Such kinds of compoſts may be uſed for any crop, and when ſufficiently pulverized, are excellent for a top dreſſing to paſtures; the parts being gradually crumbled down, and beaten into the ſoil by the feet of cattle, or waſhed in by rains. Some are of opinion, that no advantage reſults from mixing dung with earth; a bottom of earth, however, muſt always be uſeful to detain the moiſture that flows from the dung. Quicklime mixed with the dung is uſeful, by keeping the mucilage in a proper ſtate, and preventing the putrefaction from proceeding to too great a length. It has been obſerved, that making compoſt dunghills is a general practice in Norfolk. The principal ſource of them is the ſhovelings of ditches, which are found there to be ſingularly fertile. It is not the ſediment of water from the incloſures, but it conſiſts entirely of dead weeds, leaves of the hedge, and the mouldering of the bank and ſides of the ditch. The moſt barren ſub-ſtratum, expoſed a few years in the face of a ditch bank, is frequently changed into a rich black mould. Perhaps the ſea air, acting upon a looſe porous ſoil, may aſſiſt in producing this change. Other ſources of manure are uſeleſs turf, the backs of ditch-banks, the borders of fences in general, the ſides of lanes, the nooks of yards, and which, in many places, are ſuffered to remain the nurſery of weeds. Theſe are turned up into ridges, to rot the roots of the graſs and weeds, and to receive the melioration of the air; which done, they are carted in due ſeaſon to the dunghill, to be well incorporated with that ſubſtance. It is ſtated as a good and effectual mode of raiſing a large quantity of compoſt manure, to bed the farm-yard about two feet deep with earth, and on this cleanſe the ſtables, cow-houſes, hog-ſties, &c. and to move the cribs in which looſe cattle are fed, with ſtraw about it. This bed of earth will retain the urine, ſo that, when the whole is mixed together, it will all be nearly of equal goodneſs, and admirably adapted to gravelly and looſe ſoils in general, through which the eſſence of dung alone would be waſhed in one ſeaſon; and a top dreſſing of ſoot, pigeons' dung, &c. would laſt but one crop, and very rotten pure dung would be little better. Having the drains from the ſtables, cow-ſheds, and other offices, made ſo as to diſcharge themſelves into places where theſe different ſorts of earthy materials are depoſited, might be a cheap and expeditious method of procuring good compoſt-manure. And another good method of raiſing compoſt dunghills is by making them into clamps. Make a layer of hedge earth from a grubbed border, two feet deep, and about twelve feet ſquare, in the beginning of November; the quantity of earth will be about twenty-ſix loads of ſixteen buſhels each; on this clean all the yards and ſheds. The yard not being bedded with earth, ſhould be well littered, to ſoak up the urine, and to be made into dung by the hogs and looſe cattle; this may be cleaned once a fortnight, and the ſheds once a week, and piled regularly on the foundation of earth, until the heap is about ſeven feet high; and when one clamp is thus filled up, another foundation of earth may be laid adjoining to it. In order to enrich the compoſt, the flowings of the heap ſhould be prevented from running off, and thrown up occaſionally on it. By thus piling the compoſt in clamps, it will be in very good order for arable land early in the ſpring; which will not be the caſe if it be left to be trodden flat over the whole yard, and every particle waſhed by the rain. Fermentation goes on much quicker in this method; and it would be better ſtill if the heap were made under a roof, to keep off all water but what is thrown up. Another advantage of this method is, that any part of the compoſt may be uſed, by taking a diviſion of the hill that has been the longeſt finiſhed, and is conſequently in the moſt ſuitable ſtate for application. See Dung.

It is found that all ſorts of animal ſubſtances, mixed with earth, litter, or any vegetable material, make a rich compoſt. Saw-duſt, mixed in layers with the blood and offal of a ſlaughter-houſe, and incorporated till the whole becomes a moiſt fetid maſs, is a rich compoſt. Two loads of it, with three loads of earth. will be ſufficient for an acre of wheat or ſpring corn. Being a kind of top dreſſing, it ſhould be put on at the time of ſowing, and harrowed in with the grain. This kind of manure is beſt adapted to lands of an open texture. Tough clays require lime, and plenty of dung, to break the cohesion of their parts. As this compoſt takes up little room, it is very convenient for the uſe of ſuch farmers as are obliged to bring manures from a diſtance: it is alſo extremely rich, and will probably continue longer in the land than yard or ſtable dung. All animal ſubſtances being of the ſame nature, the refuſe of whale-fat, after the oil is boiled out, will make a rich compoſt with freſh dung, which will reduce the blubber ſpeedily into a putrid ſtate, or with earth and dung. Having marked out the length and breadth of your intended dunghill, make a layer of earth, ſuch as moor earth, or that of ant-hills, about a foot in thickneſs; over this put a layer of yard or ſtable dung of the ſame thickneſs, then a layer of blubber, and over that another layer of dung. Repeat the operation till the heap be raiſed about ſix feet, then give it a thick covering of earth, and coat the heap with ſods. In about a month, turn the whole in the uſual manner; and when turned, coat with earth as before, to confine the putrid ſteam. In a month or two, the heap will be conſiderably fallen, when it ſhould have a ſecond turning. This operation muſt be repeated at proper intervals, till the whole becomes an uniform putrid maſs. In general, this compoſt ſhould not be uſed till it is a year old. The heap muſt be guarded from dogs, ſwine, &c. This compoſt may with great advantage be applied to all purpoſes where good rotten dung is required. It is excellent for cabbages and for meadow ground. One hogſhead of whale refuſe will make eight loads of dung; and muſt be of great importance to ſuch farmers as lie at a diſtance from manure, but within reach of thoſe places where train oil is prepared. The practice of throwing this kind of offal into the ſea was highly wrong and inconſiderate. And it is obvious, that the refuſe of all ſorts of fiſh, and fiſh itſelf, when in ſhoals too great for conſumption in the way of food, may advantageouſly be made into a compoſt in the way above deſcribed. Theſe are local advantages; and are mentioned principally with a view to put farmers upon ſearching diligently for ſuch ſubſtances as are within their reach, that are capable of aſſiſting the ſheepfold and common dunghill, upon which in many places they rely wholly, however inadequate to their wants; abundance of good manure properly managed, being the life and ſoul of huſbandry. Where there is a deficeney of materials for making good compoſts, proper for the ſoil in many caſes, a mixture of different ſoils may anſwer the purpoſe. Thus, where clay predominates, the addition of ſand, where it is happily within reach, is often ſufficient to enſure fertility; and where ſand prevails, the addition of clay or chalk will anſwer the ſame purpoſe. Gravel enriches peat-moſs; and that in return improves gravel. The farmer ſhould, therefore, ſearch every where above ground and below, for ſuch ſubſtances as may improve his ſeveral ſoils, by being properly mixed with them.

In conſidering the nature of manures, and the methods of applying them to lands, under different circumſtances, further directions will be given in regard to the making and applying of compoſts. See Manure.

COMPOSTELLA, or St. Jago de Compostella, in *Geography*, a city of Spain, and capital of the province of Gallicia, with an archbiſhop's ſee and an univerſity, ſituated in a peninſula formed by the rivers Tambra and Ulla. N. lat. 42° 54′. W. long. 7° 17′. It has a great number of nunneries and monaſteries, and contains about 2000 houſes. The public ſquares, the churches, and particularly the cathedral, are magnificent. The Spaniſh military order of St. Jago derives its origin from this place, where the body of St. James is reported to lie buried, which circumſtance likewiſe uſed to draw a vaſt concourſe of pilgrims from moſt parts of Chriſtendom in former times.

The number of pilgrims who went thither from England in 1428, amounted to 916 perſons; in 1433 the number was 520; in 1434, 2460, and in 1445, 2100. It was the practice for the crown to grant licenſes to maſters of ſhips for carrying out a limited number of theſe votaries of ſuperſtition, who took with them conſiderable ſums of money, not only for their neceſſary expences, but for offerings and other charges incurred by this pilgrimage. See St. Jago.

Compostella *Nueva*, or *New Compoſtella*, a rich town of North America, in Old Mexico, or New Spain, in the province of Xaliſco, built by Nunez de Guſman in 1531, near the South ſea; 400 miles N.W. of Mexico. The ſoil is barren and the air inſalubrious; but it has ſeveral mines of ſilver at St. Pecaque, in its neighbourhood. N. lat. 21° 20′. W. long. 110° 12′.

COMPOUND, the reſult or effect of a compoſition of different things; or that which ariſes from them.

Strictly ſpeaking, every new compoſition does not produce a new compound; but only that from which a new eſſence ariſes. Thus, when one drop of water is added to another, there does not ariſe a new phyſical compound; the eſſence being the ſame now as before the union.

Compound differs from complex, and ſtands oppoſed to ſimple, which ſee reſpectively.

Compound, in *Botany*, applied to leaves, expreſſes their being compoſed of more than one piece, or leaflet, connected by a common footſtalk, which is either ſimple or branched. *Folium decompoſitum* is applied to a leaf more than once compounded, and *ſupra-decompoſitum* to any greater degree of ſuch conformation. See Leaf.

A compound flower is limited by Linnæus to that particular kind of aggregate flower, (ſee Aggregate,) whoſe florets are ſeſſile on a common receptacle, within a common calyx, and furniſhed with anthers united into a tube. Theſe are the excluſive characters of the great natural claſs *Syngeneſia*, the 19th in the Linnæan Syſtem, the laſt order of that claſs, *monogamia*, conſiſting of ſimple flowers, being now, by general conſent, diſuſed. Compound flowers conſiſt either of uniform perfect florets, each furniſhed with ſtamens and piſtils, and all ripening perfect ſeed; or of ſuch florets in the diſk, with female, or even neutral, ones in the radius; or, laſtly, of male florets in the diſk and female florets in the radius. Their partial corollas are either tubular and five-cleft, or ligulate, ſtrap-ſhaped. Their manner of becoming double is for the tubular and perfect florets of the radius to become ligulate and female only, or even neuter, which change is often extended to all the florets, even to the centre, in which caſe no ſeed is perfected. Sometimes the ligulate florets become not only abortive, but tubular, or quilled. The prevailing colour of compound flowers is yellow, eſpecially their diſk. The ligulate radius is often white, red, or blue, with a yellow diſk, but if the radius be yellow, the diſk is never of any other colour, except what ariſes from the anthers or ſtigmas.

COMPOUND *Force, Forms, Foſſils, Fractions, Fracture, Gland, Harmony.* See the ſubſtantives.

COMPOUND *intereſt*, called alſo *intereſt upon intereſt*, is that which is reckoned not only upon the principal, but upon the intereſt itſelf forborn; which hereby becomes a ſort of ſecondary principal. See INTEREST.

COMPOUND *Larceny.* See LARCENY.

COMPOUND *Machine, Maſonry.* See the ſubſtantives.

COMPOUND *motion,* that motion which is effected by ſeveral conſpiring powers.

Powers are ſaid to conſpire, if the direction of the one be not directly oppoſite to that of the other; as when the radius of a circle is conceived to revolve about a centre; and at the ſame time a point to move ſtraight along it.

All curvilinear motion is compound.

It is a popular theorem, in *Mechanics,* that in an uniform compound motion, the velocity produced by the conſpiring powers, is to that of either of the powers ſeparately, as the diagonal of a parallelogram, according to the direction of whoſe ſides they act ſeparately, to either of the ſides. See COMPOSITION *of motion.*

COMPOUND *numbers.* See COMPOSITE.

COMPOUND *pendulum,* in *Mechanics,* that which conſiſts of ſeveral weights conſtantly keeping the ſame diſtance, both from each other, and from the centre about which they oſcillate. See PENDULUM.

COMPOUND *propoſition.* See PROPOSITION.

COMPOUND *quantities,* in *Algebra,* are ſuch as are connected together by the ſigns + and −: thus, $a + b - c$, and $bb - b$ are compound quantities.

COMPOUND *ratio* is that which the product of the antecedents of two or more ratios has to the product of their conſequents. Thus 6 to 72 is a ratio compounded of 2 to 6, and 3 to 12. See PROPORTION and COMPOSITION *of ratios.*

COMPOUND *Sounds, Surd, Taſte, Ulcer, Words.* See the ſubſtantives.

COMPOUND *ſtops* on an organ, are ſuch wherein each finger-key acts upon two, three, four, or even five pipes of different pitches, and cauſes them all to ſound together, whenever a key in this ſtop is put down. The moſt common of theſe are the CORNET, the SESQUIALTER, and the MIXTURE, or furniture ſtops, (ſee theſe articles;) the uſe of theſe compound ſtops with others which are not tuned to the actual note which they repreſent, or that on the diapaſon ſtop, but to the XIIth or XVIIth thereof (ſee TWELFTH, TIERCE, and LARIGOT, *Stops*) is to introduce an inconceivable number of actual diſcords into the common chord, even during full performances, as any perſon may, at leiſure, ſatisfy himſelf, by writing down the ſeveral notes produced by a chord formed of the ſtops above-mentioned, combined with the diapaſon and other uniſonant ſtops, or by putting down all the keys on a piano-forte at the ſame time, to which a chord on theſe ſtops anſwers. No problem in the ſcience of harmonics is more difficult of ſolution, than to account for the ear's receiving pleaſure from ſuch a confuſed and diſſonant aſſemblage of ſounds: and it can only perhaps be accounted for by ſuppoſing, that the concordant notes being ſo many more in number in theſe kinds of chords, overpower and drown the diſcords to ſuch a degree, that the ear is able by a ſort of mental exertion to paſs over and not attend to the latter, any more than to the rattling of the keys of a badly conſtructed harpſichord, or the noiſe of carriages in the ſtreet adjoining a concert-room, &c.

COMPOUNDED IDEA, in *Logic,* unites ſeveral ideas of a different kind, which are uſually conſidered as diſtinct ſingle beings, whether thoſe united ideas be ſimple or complex. See COLLECTIVE *idea.*

COMPOUNDING FELONY, in *Law.* See THEFT-BOTE.

COMPOUNDING *of informations* upon penal ſtatutes, is an offence of an equivalent nature to CHAMPERTY in criminal cauſes; and, beſides, it is an additional miſdemenſor againſt public juſtice, by contributing to make the laws odious to the people. At once therefore to diſcourage malicious informers, and to provide that offences, when once diſcovered, ſhall be duly proſecuted, it is enacted by ſtatute 18 Eliz. c. 5, that if any perſon, informing under pretence of any penal law, makes any compoſition without leave of the court, or takes any money or promiſe from the defendant to excuſe him, (which demonſtrates his intent in commencing the proſecution to be merely to ſerve his own ends, and not for the public good), he ſhall forfeit 10*l.*, ſhall ſtand two hours on the pillory, and ſhall be for ever diſabled to ſue on any popular or penal ſtatute.

COMPREHENSION, in *Engliſh Church Hiſtory,* denotes a ſcheme propoſed by ſir Orlando Bridgman in 1667-8, for relaxing the terms of conformity in behalf of proteſtant diſſenters, and admitting them into the communion of the church. A bill for this purpoſe was drawn up by lord chief baron Hale, but diſallowed. A project to the ſame purpoſe was propoſed and argued in parliament ſoon after the reſtoration, in 1661; but the royaliſts and zealous churchmen formed a majority, and the endeavours of thoſe who wiſhed to avail themſelves of the king's declaration to this effect, proved ineffectual. The attempt was renewed by Tillotſon and Stillingfleet in 1674, and the terms were ſettled to the ſatisfaction of the non-conformiſts, but the biſhops refuſed their aſſent. This ſcheme was likewiſe revived again immediately after the Revolution; the king and queen expreſſed their deſire of an union: however the deſign failed after two attempts; and the act of TOLERATION was obtained. Birch's Life of Tillotſon, p. 42, 167, &c.

COMPREHENSION, in *Metaphyſics,* is that act of the mind, whereby it apprehends, or knows, any object preſented to it, on all the ſides, whereon it is capable of being apprehended, or known.

To comprehend a thing, is defined by the ſchoolmen, *rem aliquam totam & totaliter cognoſcere.* See APPREHENSION.

COMPREHENSION, in *Rhetoric,* a trope, or figure, whereby the name of a whole is put for a part; or that of a part for a whole: or a definite number of any thing for an indefinite.

COMPREIGNAC, in *Geography,* a town of France, in the department of the Upper Vienne, and diſtrict of Bellac; 10 miles N. of Limoges.

COMPRESS, in *Surgery,* from the Latin word *comprimere,* to preſs together, is a bolſter of linen cloth folded ſeveral times, and employed on various occaſions.

Compreſſes are formed ſometimes of lint or ſurgeon's tow, but more commonly of half-worn linen without ſeam or ſelvage. The ſize, thickneſs, and form of them, muſt be regulated by the part to which they are applied, or the object which the ſurgeon has in view.

When they are intended to cover other dreſſings to a wound, &c., they muſt be always larger than the ſubjacent plaſters, and muſt lie upon the part in an equal and even manner, ſo as to retain the dreſſings ſteadily on the affected part.

Compreſſes are divided into ſimple and graduated. A ſimple compreſs conſiſts of linen or flannel folded from two to eight times; and are made quadrangular, triangular, or with pieces cut off a ſquare at the corners, ſo as to give the compreſs a crucial form, &c. A graduated compreſs conſiſts in a number of ſimple ones laid one above the other, and ſometimes ſewed together in the ſhape of a pyramid; theſe latter are uſed for compreſſing a bleeding artery, or they are applied to the bottom of a fiſtulous ſore, or to the ſides of a deep fleſhy wound, or upon ganglions, and ſome other tumours, in order to diſperſe them.

Compreſſes are employed to fill up inequalities, or hollow parts of the body; they are alſo uſed to guard wounds againſt the contact of irritating ſubſtances, and ſometimes merely to receive the purulent diſcharge. They are frequently moiſtened with different medicated fluids, and are applied either warm or cold according to the ſurgeon's intention.

Compreſſes are ſometimes of conſiderable length, and of little breadth, eſpecially when employed to the extremities of the body in a circular form, after the manner of common bandages. (See BANDAGE.) The latter kind of bandage is named by the French *longuette*. The methodical application of ſuch compreſſes has effected a cure in ſome aneuriſms: they are alſo found particularly uſeful in ſinuoſities and deep ſores, where matter is apt to collect and require counter openings. From the various uſes of compreſſes, writers have named them contentive, uniting, diverſive, &c.

Tourniquets, truſſes, and ſome other ſurgical inſtruments, are only particular kinds of compreſſes. (See ANEURISM, and HERNIA.) Compreſſion is now and then made very advantageouſly by means of the finger only, and will often ſtop a violent bleeding in parts where no ſurgical apparatus can be employed. Thus the root of the noſe is compreſſed with the fingers, in order to ſtop violent ſneezing, and the crown of the teeth in order to relieve the tooth-ach; and in order to make polypi ſuppurate, ſphacelate, or fall-off, their roots are compreſſed between the fingers. A great number of the bandages that are uſed, produce their effects merely by the ſupport which they give to the parts.

The diverſity of caſes in which a ſkilful ſurgeon will employ compreſſion with advantage, cannot here be detailed; but in addition to what has already been ſaid, we may add that by this means alone dropſical ſwellings may frequently be diſſipated; and of this, Mr. John Bell records a ſtriking example in his "Principles of Surgery," 4to. vol. i. p. 128, where he treats of bandages in general. By the way, we may mention, that Mr. John Bell has here given ſome excellent general obſervations; but (as in other parts of his writings) he affects to have read in authors what no one elſe can find; and in the inſtance before us, he pretends to have read "the treatiſes of Soranus, Glaucus, and Diocles, in which," he ſays, "I find nothing but what has fallen into deſerved neglect;" whereas theſe authors have not written any treatiſes upon bandages that have deſcended to the preſent generation! Well might this author aſk the queſtion, "Why ſhould we go back to the ancients in this pitiful manner?"

COMPRESSED *Foſſils*, this term is applied by naturaliſts to various extraneous ſubſtances found in the earth, which ſeem to have ſuffered a flattening or change of ſhape, from the weight of the ſuperincumbent ſtrata; this is not uncommon with foſſil ſhells, of large ſize compared with their thickneſs, as echini, &c., and ſhould be particularly noted in deſcribing the circumſtances of any ſtratum, where ſuch compreſſed foſſils appear.

The mountains of Quedliac and Portfiallet in Norway, contain an argillaceous pudding-ſtone, the ſiliceous pebbles of which have been thought by ſome to be compreſſed, becauſe thoſe in the lower part of the ſtratum are progreſſively thinner than thoſe above (Kirwan's Geo. Exp. 8.); but this probably was their original ſhape. The ſmall black chert pebbles, which form uniform layers in the lower part of the London clay ſtratum, are all of them ſomewhat flat, but certainly not by compreſſion, we think.

Bituminized wood, or the reſemblance of trunks of trees in wood-coal, is often found flattened, as at Todi, and near Aqua-Sparta in Umbria, at Thun in Switzerland, in Iceland, &c. Siliceous petrifactions have frequently ſomewhat the appearance of compreſſed wood, and have been ſo denominated; but a careful examination of ſeveral ſpecimens, in which the tranſverſe ſection preſented two equal ſegments of circles joined together by their chords, inſtead of a diſtorted ellipſis, which would probably be the form of round wood when compreſſed, has induced us to think that theſe, and probably many extraneous foſſils ſaid to be compreſſed, may originally not have been round.

Peat-foſſils of the preſent race, ſuch as the trees found in the ſea at Sutton in Lincolnſhire, and in other places, have without doubt been flattened, by the weight of peat and earth lying upon them, when in a ſoft and decaying ſtate.

COMPRESSION, from the Latin *compreſſio*, is the act of preſſing, or ſqueezing matter together, ſo as to force its parts nearer to one another, and enable the whole to occupy a ſmaller ſpace; or the effect produced by that cauſe. *Compreſſion* and *condenſation* denote the production of the ſame effect; that is, the reduction of a certain quantity of matter into a ſmaller ſpace; with this difference, however, that when the effect is produced by the application of any external force, as by the preſſure of a ſuperincumbent fluid, or by means of mechanical engines, it is more properly denominated *compreſſion*; but when the effect is produced by ſome internal action, as by the eſcape of caloric in cooling, it is then called CONDENSATION, which ſee.

Compreſſion takes place in various natural proceſſes, and it is alſo practiſed by art for various mechanical and economical purpoſes. The inquiries which may be made concerning it, are, 1ſt, the principal caſes in which compreſſion is produced in nature; 2dly, the mechanical methods which are uſed for compreſſing bodies in manufactories and in civil economy; and 3dly, the principal effects which reſult therefrom. Of the natural compreſſions, thoſe which ariſe from the weights of ſuperincumbent ſolids are ſufficiently obvious, and they will, beſides, be particularly examined under the articles GRAVITY, and MECHANICS; but thoſe which are occaſioned by fluids, being much leſs evident, are ſeldom ſufficiently underſtood even by thoſe who are concerned with them.

Water and air are the two fluids with which mankind is naturally and unavoidably concerned; and the preſſures of thoſe fluids differ materially from each other. The preſſure of water is proportionate to its perpendicular height and not to its quantity, and that preſſure is exerted in every direction; for inſtance, let two veſſels of the ſame height, but of different ſizes, as a ſmall pipe and a large reſervoir, be filled with water to the ſame height; then if you meaſure a ſquare inch in the bottom of the ſmall pipe, and a ſquare inch in the bottom of the reſervoir, the preſſure upon thoſe two different ſquare inches is the ſame; though the reſervoir may contain twenty or thirty thouſand times more water than the pipe. Alſo, if you take a ſquare inch on the ſide of the veſſel cloſe to the bottom, the lateral preſſure upon it will be equal to the preſſure on the ſquare inch of the bottom; excepting indeed a trifling difference which ariſes from the perpendicular height of the water above the latter, which barely exceeds the perpendicular height of the water above the former.

But though water preſſes upon every body that is immerſed in it in proportion to its perpendicular height, and tends to force the parts of thoſe bodies cloſer to each other, provided that thoſe bodies have not pores large enough to admit the water; yet water is not itſelf ſuſceptible of compreſſion, unleſs it be in a very ſlight, and ſcarcely perceptible degree; hence at different depths, water is nearly, if not exactly, of the ſame denſity.

The air of the atmoſphere, as well as the other aerial fluids, is highly elaſtic, in conſequence of which it not only preſſes upon all bodies that are immerſed in it: but, by preſſing upon itſelf, its own denſity is rendered different at different altitudes. The bulk of a given quantity of air has been found to decreaſe in the direct ratio of the force with which it is compreſſed; hence it has been demonſtrated, that if the altitudes above the ſurface of the earth be taken in arithmetical progreſſion, the denſities of thoſe altitudes will be in geomtrical progreſſion decreaſing If a very long tube, cloſed at one end be filled with water, and then be inverted in a baſon of water, that fluid will remain ſuſpended in it to the height of about 33 feet, that weight of water being counterpoiſed by the preſſure of the atmoſphere: (ſee the articles ATMOSPHERE, PNEUMATICS, and HYDROSTATICS.) Therefore, ſince a man on the ſurface of the earth is preſſed by the weight of the atmoſphere, if he places himſelf at 33 feet below the ſurface of the water, he will be preſſed by twice the above-mentioned weight of the atmoſphere; if he places himſelf at 66 feet below the ſurface of the water, he will ſuſtain a preſſure equal to three atmoſpheres, and ſo on.

If the abovementioned experiment be tried with a tube filled with and inverted in a cup of quickſilver, inſtead of water, it will be found that the quickſilver will remain ſuſpended in it to the height of about 30 inches, the ſpecific gravity of quickſilver being much greater than that of water. As the preſſure of the atmoſphere counterpoiſes a perpendicular pillar of quickſilver about 30 inches high, or, more accurately ſpeaking, between 28 and 31 inches; for it varies between thoſe limits (ſee BAROMETER); the weight of ſuch a pillar, let its baſe be what it may, ſhews the preſſure of the atmoſphere upon a ſurface equal to that baſe. A pillar of quickſilver, whoſe baſe is an inch ſquare, and whoſe altitude is a mean between 28 and 31 inches, weighs $14\frac{1}{2}$ pounds avoirdupoiſe; therefore, at a mean, the preſſure of the atmoſphere upon every ſquare inch on the ſurface of the earth, is equal to $14\frac{1}{2}$ pounds; and by the rule of proportion, or by ſimple multiplication, we may determine the weight of the atmoſphere upon any other given ſurface. Thus the preſſure of the atmoſphere on a ſquare foot, (which is equal to 144 ſquare inches) is 2088 pounds. The preſſure on the body of a middle ſized man, whoſe ſurface is equal to about 12 ſquare feet, is 25056 pounds; and the preſſure on the ſurface of the whole earth is equal to about 11642019840000000000 pounds. For further explanation of the mechanical properties of fluids in general, ſee the articles referred to above, and likewiſe the article ELASTICITY.

The artificial methods of compreſſing ſubſtances, either ſolid or fluid, as employed in the arts, and for economical purpoſes, are very numerous; different compreſſing inſtruments being uſed for almoſt every particular purpoſe. Thus there are hammers, levers, ſcrew-preſſes, hydraulic preſſes, condenſing engines, rolling or flatting mills, &c. Thus the apothecary obtains his expreſſed oils by means of a ſcrew-preſs, the book-binder compreſſes the leaves of his books, both with the hammer, and with a ſcrew-preſs of a different form; the gold-beater compreſſes and ſtretches his metallic plates firſt through the rolling (or flatting) mill, and then by the ſtrokes of a hammer, and ſo forth. Deſcriptions of thoſe inſtruments may be ſeen under their different names.

Beſides the above-mentioned mechanical properties, compreſſion produces ſome remarkable phyſical effects, of which it will be neceſſary to give a diſtinct account. We ſhall, however, previouſly to this, briefly ſtate the diſcoveries that have been made with reſpect to the compreſſibility of water, which, as has been already mentioned, is ſo very ſlight as to be next to nothing.

Water was, during a very long period, conſidered as a fluid perfectly unelaſtic; that is, unyielding, or incompreſſible; and this opinion was corroborated by an experiment of the Academy del Cimento in Italy. About a century and a half ago the members of that academy endeavoured to aſcertain whether water was capable of being compreſſed in any degree. For this purpoſe, they filled a hollow metallic ſphere with that fluid, and ſtopped the aperture very accurately. This ball then was preſſed in a proper machine, but no contraction could be obſerved, nor indeed was the apparatus capable of manifeſting ſmall degrees of compreſſion. Hence they concluded that water was not capable of compreſſion. This opinion prevailed until the year 1761, when the ingenious Mr. Canton diſcovered the compreſſibility of water, and of other liquids, which he immediately made known to the Royal Society. He took a glaſs tube, having a ball at one end; filled the ball and part of the tube with water, which he had deprived of air as much as it was in his power; then placed the glaſs thus filled under the receiver of an air-pump; and on exhauſting the receiver, which removed the preſſure of the atmoſphere from over the water and the glaſs veſſel which contained it, in conſequence of which the water roſe a little way into the tube, *viz.* expanded itſelf. He then placed the apparatus under the receiver of a condenſing engine, and on forcing the air into it, which increaſed the preſſure upon the water, a diminution of bulk evidently took place; the water deſcending a little way within the tube. "In this manner," Mr. Canton ſays, "I have found by repeated trials, when the heat of the air has been about 50°, and the mercury at a mean height in the barometer, that the water will expand and riſe in the tube by removing the weight of the atmoſphere, one part in 21740; and will be as much compreſſed under the weight of an additional atmoſphere. Therefore the compreſſion of water by twice the weight of the atmoſphere is one part in 10870."

"Water has the remarkable property of being more compreſſible in winter than in ſummer, which is contrary to what I have obſerved, both in ſpirit of wine and oil of olives."

By the ſame means, and in the ſame circumſtances, Mr. Canton aſcertained the property of being compreſſed in ſome other fluids, and the reſults are as in the following table:

Compreſſion	of ſpirit of wine	66	millionth parts.
	of oil of olives	48	
	of rain water	46	
	of ſea water -	40	
	of mercury -	3	

Mr. Canton was of opinion that the above-mentioned diminution of bulk under the receiver of the condenſing engine, is not to be attributed to any air contained in the water, or any of the other fluids; becauſe when he tried the experiment with water which had been forced to imbibe more than an uſual quantity of air, the compreſſion did not appear to be greater. Yet it may be obſerved, that conſidering the ſlight degree of compreſſion which water is capable of, and the difficulty of depriving water entirely of air, one might ſtill be induced to doubt whether that compreſſion is not to be attributed to the air. See Canton's account of thoſe experiments in the 52d and 54th vols. of the Philoſophical Tranſactions.

With reſpect to the effects produced by compreſſion, it is in the firſt place to be remarked, that certain bodies, when preſſed, ſuffer a derangement of form; but as ſoon as the preſſure is removed, they recover their former ſhape. Thoſe bodies are ſaid to be *elaſtic*, and they are diſtinguiſhed into *perfectly elaſtic*, when they recover their former bulk and ſhape entirely, as is the caſe with common air, and *imperfectly elaſtic*, when they recover their former ſhape only in part, which is the caſe with far the greateſt number of bodies.

When the bulk of a body is reduced by compreſſion, the ſpecific gravity of that body is proportionately increaſed; thus the ſpecific gravity of fine gold, that has been fuſed only, is 19,258; but the ſpecific gravity of the ſame, after having been hammered, is 19,362. The ſpecific gravity of pure ſilver, that has only been fuſed, is 10,474; that of the ſame hammered, 10,511. The ſpecific gravity of copper, ſimply fuſed, is 7,788; that of the ſame hammered, is 8,878, and ſo forth.

Whenever the bulk of a body, and eſpecially of a metallic one, is diminiſhed in bulk by hammering, flattening between rollers, or by any other ſort of compreſſion, its hardneſs or rigidity is increaſed at the ſame time; thus ſoft braſs, or ſilver, or copper, by hammering, or preſſing, is rendered hard and elaſtic. By the application of a degree of heat, ſomewhat lower than incandeſcence, that hardneſs or elaſticity of the metal is removed, and at the ſame time its ſpecific gravity becomes equal to what it was before the hammering. This proceſs is called *annealing* or *ſoftening*.

The other remarkable effects of preſſure may be reduced to three; namely, a modification of the action of the ſame degree of heat on bodies, an extrication of heat, and an extrication of light. When heat is applied to any body, the effects differ according as the application takes place under different atmoſpherical preſſures. On the tops of mountains, where the preſſure of the atmoſphere is conſiderably leſs than it is on the level of the ſea (in conſequence of which the quickſilver does not ſtand ſo high in the barometer in the former place as it does in the latter), water boils at a lower temperature; and ſo do other fluids. At the level of the ſea, water boils at about the temperature of 212° of Fahrenheit's thermometer; but Mr. Sauſſure found on Mount Blanc (which is reckoned the higheſt mountain of any in Europe; where the barometer ſtood at 17,05 Engliſh inches), that the heat of boiling was 185½°. From the experiments of Sir George Shuckburgh, and of Mr. De Luc, the following table of the heats of water boiling under different preſſures of the atmoſphere, which are indicated by the altitudes of the mercury in the barometer, was calculated by Mr. Kirwan.

Heat of boiling water under different barometrical altitudes

Baromᵗ.	Heat.	Baromᵗ.	Heat.
30	212°	21	195,36
29	210,28	20	193,36
28	208,52	19	191,06
27	206,73	18	188,46
26	204,91	17	185,56
25	203,06	16	184,36
24	[illegible]	15	[illegible]
23	[illegible]	14	[illegible]
22	[illegible]		

Mr. Watt obſerved, that in a very good vacuum water boils, or produces copious vapours, even when its heat is not greater than 70°. On the other hand, when water is cauſed to boil under a great preſſure, a much greater degree of heat muſt be applied: thus, in Papin's digeſter (being a ſtrong veſſel in which a quantity of water is confined) the water may be rendered nearly red-hot; and in that ſtate the diſſolving property of water is increaſed prodigiouſly. In Iceland a natural diſcharge of hot water comes out of a deep pit, and when this water falls upon the ſurface of the earth, it depoſits a white powdery ſiliceous ſubſtance, which, it is ſuppoſed, the water was enabled to diſſolve by the volcanic heat, that acted upon it under a great degree of compreſſion.

Dr. Hutton, like ſome other geologiſts, has aſcribed the formation of the various minerals chiefly to the action of ſubterraneous fire; but he thought that that action was modified by the compreſſion of the ſuperincumbent ſtrata of the earth, which rendered it capable of producing ſuch effects as could not be eaſily imitated on the ſurface of the earth; for it ſeemed to him, that under a great degree of compreſſion, volatility would expoſe to a high degree of heat ſuch ſubſtances as generally fly off in our fires, on the ſlighteſt application of heat. Hence, by their chemical relations peculiar combinations might ariſe; ſuch as are dug from the bowels of the earth. What Dr. Hutton ſuppoſed, was in a great meaſure verified by ſir James Hall, bart., who, by his numerous and well imagined experiments, has ſhewn a variety of remarkable effects, on different ſubſtances, by the action of heat modified by compreſſion; but his intereſting experiments will be deſcribed amongſt the effects of heat.

The other two remarkable effects of compreſſion on bodies, are an extrication of heat and an extrication of light. Theſe effects having been obſerved with all thoſe bodies which may be ſubjected to deciſive experiments; it may be preſumed from analogy, that the ſame effects take place in various degrees, with all bodies which are ſuſceptible of compreſſion, but not with thoſe which are not compreſſible; and, in fact, liquids which are only compreſſible in the ſlighteſt degree imaginable, cannot be heated by agitation, which is friction amongſt their particles; and there is no friction without compreſſion. As heat is evolved from a body when compreſſed, ſo when the bulk of a body is enlarged, heat is abſorbed, in conſequence of which the ſurrounding bodies are cooled; and this abſorption of heat ſeems to be directly proportioned to the enlargement of bulk. The following inſtances will illuſtrate the nature of theſe remarkable effects. The blackſmith, by about twenty ſtrokes of the hammer upon a piece of iron bar not thicker than a man's little finger, can render one extremity of it red-hot, viſible in the day light. But it is to be remarked, that the ſame extremity of the iron bar cannot be rendered

red-hot a ſecond time, unleſs it be previouſly ſoftened in the fire. The condenſation of common air, quickly performed, produces a conſiderable degree of heat; ſo much ſo, that cotton has been ſet on fire, and ſo has heated charcoal, by compreſſing the air quickly upon it. An ingenious mechanic in Paris is ſaid to have kindled tinder in tubes, or compreſſing pumps, of about a quarter of an inch in diameter, and ſix inches in length, by a ſingle ſtroke of the piſton. Steam, alſo, by mechanical compreſſion, may be made to yield its latent heat. A mixture of oxygen and hydrogen gaſes, if quickly compreſſed, takes fire and explodes with great force. The diſcharge of an air-gun is attended with a faint flaſh of light, viſible in a darkened room; and the ſudden compreſſion of the air in a tube, to the end of which a ſtrong glaſs is fitted for the purpoſe of manifeſting what paſſes within, is likewiſe attended with light.

In explanation of theſe phenomena, it is ſuppoſed, that independent of the ſpecific caloric, peculiar to every body, a quantity of it is lodged in the pores of each body, and that this may be extricated by compreſſion, in the ſame manner as water is ſqueezed out of a ſponge. But a farther examination of facts will throw more light upon the ſubject.

It is well known, that friction amongſt ſolids generates heat, which often occaſions actual inflammation and combuſtion. Thus the axles of wheels of carriages, and other machines, are ſometimes ſet on fire by the violence of the friction; thus, in a turning lathe, the pieces of work are heated to a great degree; thus, the violent colliſion of a ſteel againſt a flint, renders the abraded particles of the former perfectly red-hot. Count Rumford, willing to inveſtigate the origin of the heat produced by means of friction, inſtituted an intereſting ſeries of experiments in the workſhops of the military arſenal at Munich, where cannons are bored; in which caſe a degree of heat far exceeding that of boiling water is produced. After having examined the temperature of the metallic ſhavings, their quantity, capacity for containing caloric, &c. and finding reaſons ſufficient to account for the production of that remarkable quantity of heat which was manifeſted in the courſe of the boring, he began to conſider which way that heat might be derived, whether from the contiguous metal or from the air, and in order to determine the matter by means of actual experiment, he contrived a ſuitable apparatus, the principal part of which was intended to turn a piece of metal in a box full of water, whilſt a blunt borer acted forcibly againſt it, ſo as to produce a conſiderable degree of friction, without abrading from the piece of metal more than an inconſiderable quantity of it in a ſcaly powdery ſtate. With this apparatus, in which both the piece of metal and the borer were plunged in water of the temperature of the atmoſphere, no heat could be derived from the air. The machine which turned the piece of metal being put in motion, the water in the box, &c. began to be heated ſoon after, and in 2½ hours time, from the commencement of the operation, the water actually boiled. The reſult of this experiment ſhewed, that the heat, which had cauſed the water to boil, was not derived from the air, and from computation it appeared, that the abraded metallic powders could not furniſh it in conſequence of the change of their capacity. "Is it poſſible," count Rumford ſays, "that the heat could have been ſupplied by means of the iron bar, to the end of which the blunt ſteel borer was fixed? or by the ſmall neck of gun-metal by which the hollow cylinder was united to the cannon?" "Theſe ſuppoſitions appear more improbable even than either of thoſe before-mentioned; for heat was continually going off, or *out of the machinery*, by both theſe paſſages, during the whole time the experiment laſted. And in reaſoning on this ſubject, we muſt not forget to conſider that moſt remarkable circumſtance, that the ſource of the heat generated by friction, in theſe experiments, appeared evidently to be *inexhauſtible*. It is hardly neceſſary to add, that any thing which any inſulated body, or ſyſtem of bodies, can continue to furniſh without limitation, cannot poſſibly be a *material ſubſtance*; and it appears to me to be extremely difficult, if not quite impoſſible, to form any diſtinct idea of any thing, capable of being excited and communicated in the manner the heat was excited and communicated in theſe experiments, except in *motion*." Phil. Tranſ. for the year 1798.

It ſeems ſtrange that ſo diſtinguiſhed a philoſopher as Count Rumford ſhould be induced to admit the immateriality of heat from the reſult of the above-mentioned experiment, without adverting to the compreſſion which the metal muſt have received from the action of the borer.

Having mentioned the principal effects which ariſe from compreſſion, amongſt which the extrication of heat has been reckoned the moſt intereſting; we might now ſtate ſeveral inſtances of the contrary effect, namely, of the abſorption of heat attending the enlargement of bulk which takes place in ſeveral bodies after the removal of the cauſe which occaſioned their compreſſion. With reſpect to this, however, we need not be very prolix in this place. The hydraulic engine at Schemnitz furniſhes a ſtrong inſtance of the latter effect. That engine operates by cauſing a fall of water to compreſs air in a ſtrong veſſel, the re-action of which forces other water to riſe in another pipe for certain purpoſes. Now, in conſequence of the great height of the ſuperincumbent column of water, the air in the air-veſſel of this machine, is very much compreſſed, and it is ſaid that if the ſtop cock of this veſſel is opened, the air, in ruſhing out of it and expanding itſelf, abſorbs ſo much heat, and, of courſe, cools the adjacent bodies ſo much, as to produce a copious depoſition of moiſture from the atmoſphere, and the actual formation of ice upon the ſtop-cock. The cold produced by the evaporation of water, and eſpecially by that of ſpirituous liquors, might be likewiſe adduced as inſtances of the above-mentioned property. But the farther inveſtigation of theſe latter phenomena belongs to other branches of natural philoſophy, which will be explained in other places.

The term *compreſſion*, in aſtronomy and geography, has often been uſed to denote that diminution of the curvature of the ſurface of the earth, which has been obſerved about the poles, as if the earth had been compreſſed at the poles by ſome external force, which cauſed it to loſe its perfect ſpherical form, and to aſſume nearly that of an oblate ſpheroid; it being, however, well known that the ſpheroidical figure ariſes from the centrifugal force of the parts diſtant from the poles, which is likewiſe the caſe with the other planets. The preciſe quantity of deviation of the polar regions of the earth from the ſpherical form, or the difference between the equatorial and polar diameters, has been variouſly ſtated by different aſtronomers. Sir Iſaac Newton, ſuppoſing the denſity of the earth to be uniform, has aſſigned $\frac{1}{230}$ for the difference of the above-mentioned two diameters. Boſcovich, taking a mean of all the different meaſurements, found the difference of the two diameters equal to $\frac{1}{248}$. From other meaſurements and calculations ſince made by other able mathematicians, this difference has been reckoned equal to $\frac{1}{311}$ or $\frac{1}{300}$ by De la Lande; to $\frac{1}{321}$ by De la Place; to $\frac{1}{307}$ by Sejour; to $\frac{1}{305}$ by a late anonymous writer. Theſe latter reſults agree pretty well with the lengths of the pendulums, which have been

been found to vibrate ſeconds in different latitudes; ſo that upon the whole $\frac{1}{330}$, or a fraction not much differing from this, ſeems to be the neareſt to the true difference of diameters; and the diſagreement between the different meaſurements probably ariſes from the imperfection of inſtruments, from the partial attraction of mountains, and from the unequal denſity of the earth. See profeſſor Playfair's paper on the figure of the earth, in the Tranſactions of the R. Society of Edinburgh, vol. v. p. 1.

Compression, in *Surgery*, not only ſignifies the act of compreſſing, but denotes a claſs of diſeaſes produced by the preſſure of an extraneous body; and, in ſome caſes, a compreſſion will cauſe the moſt ſerious conſequences. For example, compreſſion of the brain, ariſing from a fracture of the cranium, and a portion of the bone in a depreſſed ſtate, may occaſion inflammation, ſuppuration, and deſtruction of that part of the brain to which the mechanical effect is applied; which will be, more or leſs, attended by comatoſe ſymptoms, and privation of ſenſe or voluntary motion. In ſuch caſes, the ſurgeon endeavours to remove the cauſe, by elevating the edge of the bone, or extracting it entirely, either with or without trepanning, as the circumſtances may indicate. (See Trepanning and Trephine.)

When the ſymptoms of a compreſſed brain are evidently marked, no time ought to be loſt in ſetting about an examination of the ſtate of the cranium, wherever appearances point out, or even lead us to conjecture, in what part a fracture may be ſituated. For this purpoſe an inciſion is to be made upon the ſpot through the integuments to the ſurface of the bone, which muſt be ſufficiently expoſed to admit of a free examination. Some authors have recommended a crucial inciſion; others one in form of the letter T; while many adviſe a conſiderable part of the integuments to be entirely removed. But as it is more agreeable to the preſent mode of practice to ſave as much of the ſkin as poſſible, a ſimple inciſion is generally preferred, unleſs the fracture run in different directions, and then the inciſion muſt vary accordingly. It will frequently happen, that a conſiderable part of the integuments muſt be ſeparated from the ſkull, in order to obtain a diſtinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed. When blood-veſſels of any conſiderable ſize are divided, either before or at the time of the examination, they ought to be allowed to bleed freely, as in no caſe whatever is the loſs of blood attended with more advantage than the preſent. When, however, it appears that the patient has loſt a ſufficient quantity, the veſſels ought to be ſecured.

After the integuments have been divided, if the ſkull be found to be fractured and depreſſed, the nature of the caſe is rendered evident; but even where there is no external appearance of fracture, tumour, diſcolouration, or other injury, if the patient continue to labour under ſymptoms of a compreſſed brain, if the pericranium has been ſeparated from the bone, and eſpecially if the bone has loſt its natural appearance, and has acquired a pale white or duſky yellow hue, the trepan ought to be applied without heſitation, at the place where theſe appearances mark the principal ſeat of the injury. Again, although no mark, either of fracture or of any diſeaſe underneath, ſhould appear on the outer table of the bone, yet there is a poſſibility that the inner table may be fractured and depreſſed. This indeed is not a common occurrence, but it happens perhaps more frequently than ſurgeons have been aware of; and where it does happen, the injury done to the brain is as great, and attended with as much danger, as where the whole thickneſs of the bone is beaten in. The application of the trepan is therefore uſually deemed a neceſſary meaſure.

But if, after the application of the trepan, it happens that no mark of injury appears either in the outer or inner table in that part, or in the dura mater below it, and that the ſymptoms of a compreſſed brain ſtill continue, a fracture in ſome other part is to be ſuſpected; or that kind of fracture termed by practitioners *counter-fiſſure*, where the ſkull is fractured and ſometimes depreſſed on the oppoſite ſide to, or at a diſtance from, the part where the injury was received. This is fortunately not a very frequent occurrence, and has even been doubted by ſome; but different inſtances of it have, beyond all queſtion, been found. If therefore the operation of the trepan has been performed, and no fracture is diſcovered, no extravaſation appears on the ſurface of the brain; and if blood-letting and other means uſually employed do not remove the ſymptoms of compreſſion, the operator is to ſearch for a fracture on ſome other part. The whole head ſhould again be examined with much accuracy; and, by preſſing deliberately but firmly over every part of it, if the ſmalleſt degree of ſenſibility remains, the patient will ſhew ſigns of pain, either by moans or by raiſing his hands, when preſſure is made over the fractured part. In this way, fractures have been frequently detected, which might otherwiſe have been concealed.

Having here conſidered every thing preparatory to the operation of the trepan, we ſhall point out the means beſt adapted for the removal or elevation of a depreſſed portion of the bone, by the uſe of that inſtrument, under the article Trepan. After the operation, the patient ſhould be placed in as eaſy a poſition, in bed, as poſſible, with his head and ſhoulders elevated a little more than ordinary. If the operation be attended with ſucceſs, he will ſoon begin to ſhew ſigns of increaſing ſenſibility, and the original bad ſymptoms will gradually diſappear. In this ſtate, he ought to be kept as quiet as poſſible; proper laxatives being occaſionally adminiſtered, and ſuch as may be leaſt of a nauſeating nature. His food ought to be ſimple and eaſy of digeſtion, and his drink of the moſt diluent kind. If he complain of the wound being uneaſy, an emollient poultice ſhould be immediately applied, and renewed three or four times in the twenty-four hours. By theſe means there will commonly be a free ſuppuration from the whole ſurface of the ſore.

Every time the wound is dreſſed, the purulent matter ought to be wiped off from it with a fine warm ſponge; and if any degree of ſloughineſs takes place on the dura mater or parts adjacent, it will then be completely ſeparated. Granulations will begin to form, which will continue to increaſe till the whole ariſe to a level with the ſurface of the cranium. The edges of the ſore are now to be dreſſed with ſome mild cerate, and the reſt of it covered with fine lint, kept gently preſſed on it by a night-cap properly ſecured. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrize kindly; and as all the ſkin has been preſerved in making the firſt inciſion, the cicatrix will be but little obſerved.

But things do not always proceed in this favourable manner. Sometimes, in a few hours after the operation, the patient is ſeized with a kind of reſtleſſneſs, toſſing his arms, and endeavouring to move himſelf in bed, while the ſymptoms of a compreſſed brain remain nearly the ſame as formerly. In this caſe, eſpecially if the pulſe be quick and ſtrong, the patient ought to be bled freely, as there will be reaſon to ſuſpect ſome tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the ſymptoms are not relieved, on account of extravaſated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in theſe caſes will be in proportion to the depth of the collection. Particular attention, therefore, ought always to be paid, to the ſtate of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found tenſe, dark coloured, elaſtic, and even livid; in which caſe, an opening becomes abſolutely neceſſary to diſcharge the extravaſated fluid. Gentle ſcratches are to be made with a ſcalpel, till a probe or directory can be introduced; upon which the membrane is to be ſufficiently divided in a longitudinal, or ſometimes even in a crucial, direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is a poſſibility of the brain protruding at the opening; but the danger from this is not equal to that ariſing from effuſed fluids compreſſing the brain. A troubleſome appearance alſo now and then follows the operation of the trepan; namely, the excreſcences called *fungi* (ſee FUNGUS), formerly ſuppoſed to grow immediately from the ſurface of the brain, but which, in general, originate from the ſurface of the dura mater or cut edge of the bone granulating too luxuriantly. After the wound is cured, only a ſmall cicatrix will remain, and, in general, the parts will be nearly as firm as at firſt, but when much of the integuments hath been ſeparated or deſtroyed, as they are never regenerated, the bone will be left covered only by a thin cuticle, with ſome ſmall quantity of cellular ſubſtance. When this is the caſe, the patient uſually wears a piece of ſilver, copper, or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practiſed in caſes of compreſſion: but it frequently happens, that inſtead of compreſſion, ſuch a degree of concuſſion takes place that no aſſiſtance from the trepan can be attended with any advantage; for the effects of concuſſion (ſee CONCUSSION) are totally different from thoſe of compreſſion, and therefore to be removed in a different manner. In Part III. of his Surgical and Phyſiological Eſſays, Mr. Abernethy ſays, the degree of preſſure which the brain can ſuſtain without great injury to the ſyſtem, probably may vary according to the diſpoſition of that organ to be affected by it, the ſuddenneſs of its application, and the direction in which it is made; and although it muſt be very difficult to obtain any preciſe knowledge on this ſubject, yet there is great reaſon to believe that the brain can bear more preſſure without injury to it, than was formerly ſuppoſed. The firſt of theſe circumſtances ſeems evident; for, in ſome perſons, a ſlight preſſure produces ſevere ſymptoms; whilſt in others a much greater degree is borne without inconvenience. Where a compreſſing cauſe does not, in the firſt inſtance, occaſion bad effects, if inflammation of the brain enſues, it ſeems then to act injuriouſly; which probably ariſes from the increaſed ſuſceptibility of the brain. We can rarely judge of the effects of preſſure when any part of the cranium is beaten in by a blow: for in that caſe the ſhock generally occaſions ſtupefaction. Internal hæmorrhages, perhaps, afford us the beſt criterion whereby to determine the effects of preſſure on the brain. A caſe (the ſeventh) which Mr. Abernethy relates, ſufficiently illuſtrates this remark, for it appears that a conſiderable hæmorrhage muſt have taken place before it deprived the patient of his faculties; ſince he walked home, undreſſed himſelf, and went to bed, after the trunk of the middle artery of the dura mater had been ruptured. In caſes of apoplexy, alſo, the hæmorrhage is generally very large, before it produces thoſe conſequences which deſtroy life.

Compreſſion of the brain will ſometimes ariſe from the luxuriant growth of a part of the inner table of the ſkull, or a ſmall projecting piece of bone, which may have advanced ſpontaneouſly; and it has now and then been diſcovered that epileptic fits aroſe from this cauſe. In apoplexy, the common cauſe of a compreſſion of the brain is effuſed blood or ſerum. When perſons have a palſy of the lower extremities from incurvation of the ſpine, the paralyſis ariſes from compreſſion made on ſome part of the ſpinal marrow by a diſeaſe of the vertebræ; and nothing can relieve a patient effectually in this caſe, unleſs the preſſure be removed by extending the ſpinal column mechanically. (See *Curvature of the* SPINE.)

A dangerous compreſſion may be produced in different parts of the body, by the exiſtence of tumours, by diſlocation of the joints, or by fractures, &c. See TUMOUR, DISLOCATION, and FRACTURE.

COMPRESSOR *Naris*, or *Narium*, in *Myology*, is a muſcle of the noſe, deſcribed alſo under the name of conſtrictor naſi. It ariſes from the root of the ala naſi, where its fibres are ſtrongly connected with the depreſſor labii ſuperioris et alæ naſi, and are alſo mixed with thoſe of the depreſſor alæ naſi. It aſcends on the dorſum of the noſe, and ſcatters its fibres between the ala and the oſſa naſi; they are partly joined with the fibres of the oppoſite muſcle, and partly connected with thoſe of the frontal portion of the fronto-occipitalis. By drawing down the moveable part of the alæ naſi, and bringing it to the ſeptum, it cloſes the aperture of the noſtrils: in this caſe the depreſſor alæ naſi muſt concur with it, in order to render the inferior part of the ala fixed. If this latter muſcle does not act at the ſame time, the compreſſor naris will elevate the lower portion of the ala, and thereby expand the noſtril. Cowper calls it elevator alæ naſi: Santorini and Winſlow, tranſverſalis naſi.

COMPRESSOR *proſtatæ*. It ſeems doubtful whether this ſhould be conſidered as a diſtinct muſcle, or only as a portion of the levator ani. It ariſes from the under ſurface of the arch of the pubis, and is loſt between the proſtate and rectum. It will therefore have the power of elevating or compreſſing the former part.

COMPRINT, a ſurreptitious printing of one bookſeller's copy by another perſon, for gain; which was contrary to common law, and is now, under certain limitations, reſtrained by ſtatute. See LITERARY *Property*.

COMPRISE NIENT. See NIENT.

COMPROMISE, a treaty or contract, whereby two contending parties eſtabliſh one or more arbitrators, to judge of and terminate their differences in an amicable way.

The regular way of appointing a compromiſe is by a writing, expreſſing the names of the arbitrators, the power of chooſing an umpire, or ſuper-arbitrator, in caſe of need, a time limited for the arbitrage, and a penalty on the party who does not abide by the deciſion.

By the civil law, a ſlave cannot make a compromiſe without the leave of his maſter, nor can a pupil without the authority of his guardian, or a wife without that of her huſband. So a ſlave, a deaf or dumb man, a minor, and the perſon who is a party in the cauſe, are incapable of being choſen arbitrators in a compromiſe.

The occaſions on which a compromiſe is not allowed of, are reſtitutions, marriage-cauſes, criminal affairs, queſtions of ſtate; and, generally, any thing wherein the public intereſt is more concerned than that of private perſons.

In our law, a compromiſe is not of ſo much extent. Weſt defines it the faculty, or power of pronouncing ſentence between perſons at controverſy, given to arbitrators by the mutual private conſent of the parties, without public authority.

Matters compromiſed are alſo matters of law referred, or made an end of. See Arbiter and Arbitration.

Compromise is alſo uſed in beneficiary matters; where it ſignifies an act, whereby thoſe who have the right of election, transfer it to one or more perſons, to elect a perſon capable of the office or dignity.

COMPS, in *Geography*, a ſmall town of France, in the department of the Var, and chief place of a canton in the diſtrict of Draguignan; ten miles N. of Draguignan. It contains 739 and the canton 2949 inhabitants. The territory includes 325 kiliometres and 9 communes.

COMPSA, Conza, in *Ancient Geography*, a town of Italy, in Samnium, towards the ſouth-eaſt, upon the Aufidus. At the ſiege of this city was killed Milo, ſo well known by Cicero's oration on occaſion of his murder of Clodius. See Compza.

COMPSATUS, a river of Thrace, mentioned by Herodotus, which ran from north to ſouth, and diſcharged itſelf into the lake Biſtonis, near Abdera.

COMPTE, Lewis le, in *Biography*, a native of Bourdeaux, and of the order of jeſuits, went to China in the character of miſſionary in the year 1685. Upon his return, he publiſhed "Memoirs on the preſent State of China," &c., in two vols. As an hiſtorian he has been accuſed of a too great partiality for the character and manners of the Chineſe, and of attributing to them earlier advances in civilization and improvement than he was warranted by real facts. His work was proſcribed, and condemned to the flames, as the beſt means of refuting his opinions. He died at his native place in the year 1729. Nouv. Dict. Hiſt.

COMPTE, Nicholas de, a French monk, a native of Paris, is known as the author or editor of different works which have met with a favourable reception. Among others, he publiſhed "The remarkable Travels of Peter della Valle, a Roman Gentleman, tranſlated from the Italian, in 4 vols. 4to."—"A new and intereſting Hiſtory of the Kingdoms of Tonquin and Laos, in 4to." tranſlated from the Italian of father Manni, in 1666. In the year preceding this, he publiſhed the third volume of father Lewis Coulon's "Hiſtory of the Jews." He died at Paris in 1689.

COMPTING, or Counting-house, an office in the king's houſhold, under the direction of the lord ſteward, ſo called, becauſe the accompts for all expences of the king's houſhold are there taken daily by the lord ſteward, comptroller, cofferer, maſter of the houſhold, the clerks of the green-cloth, and the clerks comptrollers. They alſo there make proviſion for the houſhold, and make payments, and orders, for the good government thereof.

In the compting-houſe is the board of green-cloth.

COMPTON, Henry, in *Biography*, an eminent Engliſh biſhop, was the youngeſt ſon of Spencer, the ſecond earl of Northampton. He was born in the year 1632, and, though deprived of his father by death at a very early age, was initiated with great care in the rudiments of learning, after which he was entered at Queen's college, Oxford, where he proſecuted his ſtudies with much diligence, till the year 1652. From the univerſity he went to the continent, with a view of perfecting himſelf in the modern languages, and of acquiring an accurate knowledge of foreign eſtabliſhments, eccleſiaſtical and civil. On his return, he accepted under Charles II. a cornet's commiſſion in the king's horſe guards, which he ſoon reſigned and devoted himſelf to the ſervice of the church. He was immediately admitted to the degree of maſter of arts in the univerſity of Cambridge, and afterwards obtained the grant of the next vacant canonry of Chriſt-church, Oxford. In 1666, he was admitted canon-commoner of that college, and ſhortly after was in poſſeſſion of the rectory of Cottenham in Cambridgeſhire. He was in the following year made maſter of St. Croſſe's hoſpital near Wincheſter, and in 1669 inſtalled canon of Chriſt-church. Without farther delay he took the degrees firſt of bachelor of divinity, and then of doctor of divinity. In 1674 he was nominated to the biſhopric of Oxford, where he remained but a ſingle year, when he was appointed dean of the royal chapel, and tranſlated to the ſee of London. For theſe valuable and highly important preferments, Dr. Compton was indebted as well to his own excellent character as to his family connections. Soon after he had been made biſhop of London, he was ſworn in of his majeſty's privy council, and undertook the ſuperintendency of the religious education of the princeſſes Mary and Anne. To the conſcientious diſcharge of his duty as a preceptor may be juſtly aſcribed the zealous attachment of his pupils, afterwards ſovereigns of England, to the Proteſtant religion, as by law eſtabliſhed. This worthy prelate endeavoured to deviſe methods of reconciling the diſſenters to his own church; his intentions were unqueſtionably good, but ſome of the means which he uſed to effect his purpoſe could not be juſtified on the principles of proteſtantiſm. Under the pretence of guarding the church from hereſy, he obtained a royal mandate to prohibit certain diſcuſſions on the doctrine of the Trinity: he nevertheleſs ſhewed himſelf a decided friend to the Proteſtant reformation, and encouraged his clergy to defend it with Chriſtian zeal, when the principles of popery, or a moſt blameable indifference to all religion, were encouraged by the profligate court of Charles II. His conduct, in this reſpect, which cannot be too highly applauded, rendered him obnoxious to the king and to his brother, who ſoon after aſcended the throne as James II. The name of the excellent prelate was immediately after this event ſtruck out of the liſt of the privy council, after which he was deprived of his office as dean of the royal chapel. For refuſing to become an inſtrument of eccleſiaſtical tyranny among his own clergy, and to ſanction various unconſtitutional meaſures of the king, he was, in 1686, ſuſpended from his epiſcopal office. In 1688 the dread of a revolution in favour of the prince of Orange, induced the king to attempt regaining the affection of Dr. Compton, and that of the other clergy, who had been ſimilarly treated, by reſtoring them to their office. It was, however, too late to effect a reconciliation, and the biſhop ſhortly after took a decided part in favour of the new order of things. He joined in conducting the princeſs Anne of Denmark from London to Nottingham; in ſigning the aſſociation begun at Exeter, and in waiting on the prince of Orange at the head of his clergy, to thank him for his interference in preſerving the laws and liberties of the nation; and in the houſe of peers he voted for the prince and princeſs of Orange in the room of the abdicated king. Immediately after this event had been determined on, he was reſtored to the office of privy counſellor, and to that of dean of the royal chapel; he had alſo the honour of performing the ceremony at the coronation of king William and queen Mary, inſtead of archbiſhop Sancroft, who refuſed to take the oaths to the new government. In the year 1689 he was appointed one of the commiſſioners for reviewing the liturgy, and preſident of the convocation, in which certain propoſed amendments were to be diſcuſſed. In this ſituation he at firſt joined the moderate party, who were for comprehending diſſenters by adapting the liturgy to their minds, but afterwards he united himſelf with thoſe members who adviſed and obtained the diſcontinuance of the convocation ſeſſion. Dr. Compton was appointed, as biſhop of London, a commiſſioner of trade and plantations, and in this capacity he ſelected and ſent over to the colonies in America, ſuch clergymen as he thought beſt adapted, by their talents and zeal, to promote the intereſts of the church of England. In the year 1690, he attended the king, at his own expence, to the congreſs at the Hague, where the grand alliance againſt France was concluded. From this period he united himſelf more cloſely with the tory party, in conſequence of which his influence at the court of king William was greatly diminiſhed, if not wholly terminated; but in the reign of queen Anne, he recovered his former power and intereſt. Dr. Compton was in the commiſſion for promoting the union of Scotland with England; he was aſſiduous in obtaining the act for augmenting ſmall livings, by a grant of the firſt fruits and tenths; and he maintained a friendly correſpondence with the foreign Proteſtant churches, and the univerſity of Geneva, with a view of impreſſing them with favourable ſentiments towards the Church of England, and of obtaining their diſapprobation of thoſe who ſhould diſſent from its diſcipline. He died at Fulham in the year 1713, in the eighty-firſt year of his age. For ſome time before his deceaſe he is repreſented to have been much in the power of others, and to have followed their will rather than the dictates of his own mind. Through the whole of a long life he was exemplary in his moral conduct, and diſplayed the manners of a gentleman. He was a warm friend, a generous patron, and truly charitable to the wants of thoſe about him. As a biſhop he maintained the intereſts of the church, and was attentive to the conduct and advancement of his clergy, but as a preacher he was extremely dull and inanimate. His character as a literary man was reſpectable, though his works are not numerous nor of the firſt rank in merit. He publiſhed a tranſlation from the Italian of "The Life of Donna Olympia Maldachini, who governed the church during the time of Innocent X." "The Jeſuits' Intrigues with private Inſtructions of that Society to their Emiſſaries," tranſlated from the French. "A Treatiſe of the Holy Communion," and letters to the clergy at different periods, which were reprinted in 1686, under the title of "Epiſcopalia, or Letters of the Right Reverend Father in God, Henry Lord Biſhop of London, to the Clergy, &c." He alſo publiſhed "A Letter on Non-reſiſtance," which may be ſeen in memoirs of Mr. John Kettlewell. Biog. Brit. Tindal's Continuation of Rapin, vol. vi. &c.

Compton, *Little*, in *Geography*, a town of the United States of America, in Rhode iſland.

COMPTONIA, in *Botany*, (ſo named by Dr. Solander, in honour of the right reverend Henry Compton, lord biſhop of London, who cultivated many exotics at Fulham.) L'Herit. Stirp. Nov. Schreb. 1764. Willd. 1644. Gært. 564. Claſs and order, *monœcia triandria*. Nat. Ord. *Amentaceæ*.

Gen. Ch. *Male flowers*. *Catkin* cylindrical; looſely imbricated all round with concave, kidney-ſhaped, acuminate, caducous, one-flowered ſcales. *Cal.* Perianth two-leaved; leaves equal, boat-ſhaped, ſhorter than the ſcale. *Cor.* none. *Stam.* Filaments three, ſhorter than the calyx, forked; anthers ſix, two-valved. *Female flowers*. *Catkin* egg-ſhaped, cloſely imbricated with ſcales ſimilar to thoſe of the male. *Cal.* Perianth ſix-leaved; leaves oppoſite, in pairs, filiform, membranous at the baſe, many times longer than the ſcale. *Cor.* none. *Piſt.* Germ roundiſh; ſtyles two, capillary. *Peric.* none. *Seed.* Nut oval, one-celled, without valves.

Eſſ. Ch. Male flowers in a catkin. Calyx two-leaved. Corolla none. Anthers forked. Female flowers in a catkin. Calyx ſix-leaved. Corolla none. Styles two. Nut oval.

Sp. C. *aſplenifolia*. Hort. Kew. 3. 334. Mart. Willd. Gært. tab. 90. fig. 7. (Liquidambar aſplenifolium; Linn. Sp. Pl. Myrica. Linn. Hort. Clif. Gale mariana. Pet. Muſ. 773. Myrti brabanticæ affinis americana; Pluk. alm. 250. tab. 100. fig. 6, 7.) *Stems* near three feet high, ſhrubby, ſlender, hairy, branched. *Leaves* from three to four inches long, half an inch broad, alternately ſinuated almoſt to the midrib, reſembling thoſe of ſpleenwort, dark green, hairy underneath, ſitting cloſe to the ſtalks. *Male catkins* lateral, erect. *Nut* oſſeous, turgidly lenticular, naked, ſmooth, ſhining, obſoletely ſtriated, of a bay colour. A native of New York, Pennſylvania, Virginia, and Carolina; cultivated by the dutcheſs of Beaufort in 1714; flowering from March to May. Boſc was well acquainted with it in Carolina, and obſerved, that the branches generally died at the end of the third year, the new wood then ſucceeding to the old, as in the rubi; it was alſo ſeldom found in fruit, though it flowered abundantly.

COMPTROL, or Controle, is properly, a double regiſter, kept of acts, iſſues, &c. of the officers or commiſſioners in the revenue, army, &c. in order to perceive the true ſtate thereof, and to certify the truth, and the due keeping of the acts ſubject to that enregiſterment. See Register.

COMPTROLLER, an officer eſtabliſhed to comptrol, or over-ſee public accounts, and to certify, on occaſion, whether things have been comptrolled and examined, or not. Thus, we have a *comptroller of the king's houſhold*, or of the accounts of the board of green-cloth: *Comptroller-general* of the cuſtoms; *comptroller* of the navy; *comptroller* of the mint; *comptroller* of the exciſe; *comptrollers* of the accounts of the army; of the chamber, &c. See Clerk.

Comptroller *of the Artillery*, is the perſon who inſpects the artillery-muſters, makes out the pay liſts, takes the accounts of ſtores and the remains of them, and is accountable to the office of ordnance.

Comptroller is alſo the name of an officer, who ſuperintends, examines, and inſpects the accounts of the army at large.

Comptroller *of the hanaper*, is an officer in chancery, attending the lord chancellor daily in term and ſeal time. This officer is to take all things ſealed from the clerk of the hanaper, incloſed in bags of leather, and to note the juſt number and effect thereof; to enter them in a book, with all the duties belonging to the king and other officers for the ſame, and ſo charge the clerk of the hanaper with them. See Clerk and Hanaper.

Comptrollers *of the pells*, are officers of the exchequer, whereof there are two, *viz.* two chamberlains clerks, who keep a comptrol of the pell of receipts, and goings-out; originally they took notes of other officers' accompts, in order to diſcover if they did amiſs.

Comptroller *of the pipe*, an officer of the exchequer, who writes out ſummonſes twice a year, to levy the farms and debts of the pipe. See Exchequer and Pipe.

He was anciently called *duplex ingroſſator*.

Comptroller's *bay*, in *Geography*, a bay of the Pacific ocean in the N.W. part of America, ſituated to the north of Cape Suckling, and of an iſland, ſtretching S. E. and N.W. about 3 leagues, and lying on the N.W. ſide of the N. E. end of Kaye's iſland. N. lat. 60° 6'. W. long. about 215° 30'.

COMPULSION, and *inevitable Neceſſity*, in *Law*, conſtitute a ſpecies of defect of will, and they denote ſuch a conſtraint upon the will, by which a man is urged to do that which his judgment diſapproves; and which, it is to be preſumed, his will (if left to itſelf) would reject. As puniſhments are only inflicted for the abuſe of that free will, which God has given to man, it is highly juſt and equitable that a man ſhould be excuſed for thoſe acts, which are done through unavoidable force and compulſion. Of this nature is the obligation of *civil* ſubjection, whereby the inferior is conſtrained by the ſuperior to act in a manner contrary to what his own reaſon and inclination would ſuggeſt; as when a legiſlator eſtabliſhes iniquity by a law, and commands the ſubject to do an act contrary to religion or ſound morality. How far the excuſe will be admitted "in foro conſcientiæ," or whether the inferior in this caſe is not bound to obey the divine rather than the human law is a queſtion, which admits of no doubt. Nevertheleſs, obedience to exiſting laws is unqueſtionably a ſufficient extenuation of civil guilt before the municipal tribunal. The ſheriff, who burnt Latimer and Ridley, in the bigotted days of queen Mary, was not liable to puniſhment from Elizabeth, for executing ſo horrid an office; being juſtified by the commands of that magiſtracy, which endeavoured to reſtore ſuperſtition under the holy auſpices of its mercileſs ſiſter, perſecution. As to perſons in private relations, the principal caſe where conſtraint of a ſuperior is allowed as an excuſe for criminal miſconduct, is with regard to the matrimonial ſubjection of the wife to her huſband; for neither a ſon nor a ſervant is excuſed for the commiſſion of any crime, whether capital or otherwiſe, by the command or coërcion of the parent or maſter; (1 Hawk. P. C. 3.) though in ſome caſes the command or authority of the huſband, either expreſs or implied, will privilege the wife from puniſhment, even for capital offences. And, therefore, if a woman commit theft, burglary, or other civil offences againſt the laws of ſociety, by the coërcion of her huſband; or even in his company, which the law conſtrues a coërcion; ſhe is not guilty of any crime; being conſidered as acting by compulſion, and not of her own will. (1 Hal. P. C. 45.) This doctrine is at leaſt a thouſand years old in this kingdom, being found among the laws of king Ina the Weſt-Saxon. (cap. 57.) This rule, however, with regard to crimes, admits of an exception in crimes that are "mala in ſe," and prohibited by the law of nature, as murder and the like. Alſo in treaſon, no plea of coverture ſhall excuſe the wife. In inferior miſdemeanors there is likewiſe an exception; for a wife may be indicted and ſet in the pillory with her huſband, for keeping a *brothel*. And in all caſes where the wife offends alone, without the company or coërcion of her huſband, ſhe is reſponſible for her offence, as much as any feme-ſole. Another ſpecies of compulſion or neceſſity is what our law calls *dureſs per minas*; which ſee. A third ſpecies of neceſſity, diſtinguiſhable from the actual compulſion of external force or fear, is, when a man has his choice of two evils ſet before him, and being under a neceſſity of chooſing one, he chuſes the leaſt pernicious of the two. Of this ſort is that neceſſity, where a man by the commandment of the law is bound to arreſt another for any capital offence, or to diſperſe a riot, and reſiſtance is made to his authority; it is in this caſe juſtifiable and even neceſſary to beat, to wound, or perhaps to kill the offenders, rather than permit the murderer to eſcape, or the riot to continue. 1 Hal. P. C. 53. There is another caſe of neceſſity, which has occaſioned much ſpeculation among the writers upon general law; *viz.* whether a man in extreme want of food or cloathing may juſtify ſtealing either, to relieve his preſent neceſſities. Grotius and Puffendorf, and many other of the foreign juriſts, maintain the affirmative; alleging that in ſuch caſes the community of goods by a kind of tacit conceſſion of ſociety is revived. Some of our own lawyers have held the ſame opinion (See Britton, c. 10. Mirr. c. 4. § 16.); though it ſeems to be an unwarranted doctrine, borrowed from the notions of ſome civilians: at leaſt, it is now antiquated; the law of England admitting no ſuch excuſe at preſent. 1 Hal. P. C. 54. However, the founders of our conſtitution have thought it better to veſt in the crown the power of pardoning particular objects of compaſſion than to countenance and eſtabliſh theft by one general undiſtinguiſhing law. Blackſt. Com. vol. iv.

COMPULSOR, formed of the verb *compellere, to oblige, conſtrain*, an officer under the Roman emperors, diſpatched from court into the provinces, to compel the payment of taxes, &c. not paid within the time preſcribed.

Theſe were charged with ſo many exactions, under colour of their office, that Honorius caſhiered them by a law in 412.

The laws of the Viſigoths mention military compulſors; who were officers among the Goths, whoſe buſineſs was to oblige the tardy ſoldiers to go into the fight, or to run to an attack, &c.

Caſſian mentions a kind of monaſtic compulſors, whoſe buſineſs was to declare the hours of canonical office, and to take care the monks went to church at thoſe hours.

COMPULTERIA, in *Ancient Geography*, a town of Italy, in Campania. It abandoned the Romans to ſurrender itſelf to Hannibal; but Fabius reſtored it by the ſword.

COMPUNCTION, formed from *compungere*, of *pungere, to prick*, in *Theology*, an inward grief in the mind for having offended God.

The Romaniſts own their confeſſion inſignificant, unleſs attended with compunction, or pricking of heart. See CONFESSION.

Among ſpiritualiſts, compunction bears a more extenſive ſignification; and implies not only a grief for having offended God, but alſo a pious ſenſation of grief, ſorrow, and diſpleaſure, on other motives. Thus, the miſeries of life, the danger of being loſt in the world, the blindneſs of the wicked, &c. are to pious people motives of compunction.

COMPURGATOR, in *Law*, one that by oath juſtifies, or clears, another's innocence. They were introduced as evidence in the juriſprudence of the middle ages, and their number varied according to the importance of the ſubject in diſpute, or the nature of the crime with which a perſon was charged. In ſome caſes theſe compurgators were multiplied to the number of three hundred. (Præf. Nicol. ad Wilkins, p. 11.). But the uſual number was eleven. It has, indeed, been held by later authorities, that fewer than eleven compurgators will anſwer the purpoſe; but ſir Edward Coke is poſitive that there muſt be this number; and his opinion is founded both on better authority and on better reaſon, for as wager of law is equivalent to a verdict in the defendant's favour, it ought to be eſtabliſhed by the ſame or equal teſtimony, namely, by the oath of twelve men. Thus Glanvil expreſſes it (l. 1. c. 9.) "jurabit duodecima manu;" and in 9 Hen. III. when a defendant in an action of debt waged his law, it was adjudged by the court "quod defendat ſe duodecima manu." Thus too, in an author of the age of Edward I., we read, "adjudicabitur reus et legem ſuam duodecima manu." And the ancient treatiſe, entitled, "Dyverſite des courts," expreſsly confirms ſir Edward Coke's opinion.

This device, which was adopted for rendering the purgation by oath more certain and ſatisfactory, was found to be ineffectual. It was a point of honour with every man in Europe, during ſeveral ages, not to deſert the chief on whom he depended, and to ſtand by thoſe with whom the ties of blood connected him. Whoever then was bold enough to violate the laws, was ſure of devoted adherents, willing to abet and eager to ſcreen him in whatever manner he required. The formality of calling compurgators proved an apparent, not a real ſecurity, againſt falſehood and perjury; and the ſentences of courts, while they continued to refer every point in queſtion to the oath of the defendant, became ſo flagrantly iniquitous as to excite univerſal indignation againſt this method of prevention. See Oath and Wager *of Law*.

COMPUTATION, the manner of accounting and eſtimating time, weights, meaſures, and money.

The word is ſometimes alſo uſed among mathematicians in the like ſenſe as Calculation.

Computation *of a planet's motion*. See Planet.

Computation is particularly uſed in *Law* in reſpect of the true account, or conſtruction of time, ſo underſtood, as that neither party do wrong to the other, nor the determination of time be left at large, or be taken otherwiſe than according to the judgment and intention of law.

A deed, dated May 11, to hold from the day of the date, ſhall be conſtrued to begin on the 12th day of May.

If indentures of demiſe be ingroſſed, bearing date May 11, 1769, to have and to hold the land in S. for three years from henceforth; and the indentures be delivered the 4th of June following: in this caſe, *from henceforth* ſhall be computed from the day of the delivery, and not from the date. And if the indentures be delivered at four of the clock in the afternoon, the ſaid 4th of June, the leaſe ſhall end the third day of June in the third year; the law, in ſuch computation, rejecting all fractions or diviſions of the day, on account of that uncertainty which is the mother of contention. In writings, ordered by the ſtat. 27 Hen. VIII. to be inrolled within ſix months, if ſuch writings have date, the ſix months ſhall be accounted from the date, and not from the delivery: if they want date, it ſhall be accounted from the delivery. Coke, lib. 5.

If a deed be ſhewn to a court at Weſtminſter, it ſhall remain in court (by judgment of law) all the term in which it is ſhewn: for all the term is but as one day in law. Coke, ibid.—If a church be void, and the patron does not preſent within ſix months, the biſhop of the dioceſe may collate his chaplain; but theſe ſix months ſhall be computed according to 28 days of the month; and not according to the calendar.

Computation *of Miles*, after the Engliſh manner, allows 5280 feet, or 1760 yards to each mile; and the ſame ſhall be reckoned, not by ſtraight lines, as a bird or arrow may fly, but according to the neareſt and moſt uſual way. Cro. Eliz. 212.

COMPUTO, a writ thus called from its effect, which is to compel a bailiff, chamberlain, or receiver, to yield his accompts. It is founded on the ſtatute of W. & M. 2. c. 12.

The ſame lies for executors of executors; and againſt the guardian in ſocage, for waſte made in the minority of the heir.

Computo *vicecomitis habendo reſpectu*. See Respectu.

COMPZA, in *Ancient Geography*, a town of Italy, in the territory of the Hirpini, towards the frontiers of Lucania. Hannibal, after the battle of Cannæ, was invited into the country of the Hirpini by Statius, who promiſed to ſurrender to him the town of Compza. The modern name is Consa or Conza. See alſo Compsa.

COMRADE is a common appellation for a fellow-ſoldier in the ſame regiment, troop, or company.

COMSHE, in *Geography*. See Comche.

COMTAT Venaissin, a country ſituated in the ſouth of France, formerly belonging to the pope, by whom it was ceded, together with its chief city Avignon, to the French government, ſoon after the revolution of 1789. It now forms part of the department of Vaucluſe.

COMTE, Count. The titles of *comte*, of *duc*, of *vicaire*, of *centenier*, or *thungen* before the time of Charles the Bald, were not hereditary in families. Theſe officers adminiſtered the finances and juſtice in the provinces: they were, at the ſame time, magiſtrates and military characters; they convoked the *ban* and *arriere-ban*. They aſſembled and conducted the troops to the general rendezvous. And when they judged a cauſe they had their ſhields on.

Comte *du Palais*. See Majordome.

COMUM, in *Ancient Geography*, a town of Gallia Tranſpadana, ſituated towards the north, on the ſouthern bank of the lake Larius. It was founded by the Gauls, became a Roman colony, and was enlarged by Scipio. Julius Cæſar eſtabliſhed Greeks in it, and then called it the new Comum, but upon their departure it loſt this epithet. It was a municipal town. Pliny founded in it ſchools and a public library. See Como.

COMUS, in *Mythology*, the god of jollity or feſtivity. There is great reaſon to believe he was the Chamos of the Moabites; Baal-Phegor, Baal-Peor, Priapus, and Bacchus. He is repreſented under the appearance of a young man, with an inflamed red countenance, his head inclined, and crowned with flowers; his air drowſy; leaning on a huntſman's ſpear in his left hand, and holding an inverted torch in his right. His ſtatue was placed at the chamber doors of new married perſons; his pedeſtal crowned with flowers.

CON, *Ital.* a propoſition, placed before many muſical terms; as *Con ario*, with the bow, after a *pirricato*, which ſee. *Con ſordini*, with the ſordini or mute. *Con affetto*, tenderly. *Con furia*, furiouſly. *Con diſcrezione*, diſcreetly, as to rapidity. *Con violini*, with violins, &c.

CONADIPSAS, in *Ancient Geography*, an ancient town of Scythia, on the other ſide of Imaus.

CONAFADOS, an epiſcopal town of Arabia, under the metropolis of Boſtra.

CONAJOHARY, in *Geography*, a poſt town of America, on the ſouth ſide of Mohawk river, in the ſtate of New York, 36 miles above Schenectady, and 318 from Philadelphia.

CONAME, in *Botany*, the name given by Aublet to a genus formed by him for a ſhrub found in Cayenne, which has ſince been conſidered as a phyllanthes. He gives it the following character. Male and female flowers on different plants. *Calyx* ſix-cleft. *Cor.* none. *Stam.* numerous. *Piſt.* Germ ſtriated; ſtyle bifid; ſtigma villous. *Peric.* Capſule ſix-celled.

CONANA, in *Ancient Geography*, an epiſcopal town of Aſia, in Pamphylia.

CONANICUT, in *Geography*, an iſland near the coaſt of America, a little to the eaſt of Rhode iſland. N. lat. 41° 25'. W. long. 71° 20'.

CONANT, John, in *Biography*, was born at Yeatenton, Devon, in the year 1608. He was entered at Exeter college, Oxford, in 1626, where he acquired great reputation for his diligence and for his talents as an able diſputant. As a claſſical ſcholar he was remarkable for the purity of his Latin ſtyle, and for his intimate and extenſive acquaintance with the Greek language. He was alſo well verſed in the ſeveral oriental tongues. In 1633, he was choſen fellow of Exeter college, where his fame, as a tutor, procured him pupils from many very reſpectable families. The commencement of the civil wars obliged him to retire from the univerſity, and he officiated for ſome time at the living of Lymington, where he was plundered of his property, and impriſoned. As ſoon as he was liberated he went to London, and became domeſtic chaplain to lord Chandos. While he continued in his lordſhip's houſe at Hanfield in Middleſex, he preached a gratuitous lecture at Uxbridge on a week day to numerous audiences. On the 7th of June 1649, he was unanimouſly choſen rector of Exeter college, without any ſolicitation on his own part. Shortly after this he was in danger of being driven out of all public employment, by the parliament's requiring his ſubſcription to the "engagement," by which a promiſe was to be given to be true and faithful to the commonwealth of England, without a houſe of lords. This he at firſt declined; having however a fortnight given him to reconſider the matter, he ſubmitted; but under a declaration, ſubſcribed at the ſame time with the "engagement," which rendered that inſtrument almoſt nugatory. He now entered upon his office as rector with increaſed zeal, and diſcharged the ſeveral duties incumbent upon him, with the utmoſt diligence and fidelity. In December 1654, he was appointed divinity-profeſſor of the univerſity of Oxford, and in three years afterwards he was raiſed to the dignity of vice-chancellor of that univerſity, which he retained till Auguſt 5, 1660. While he held this high office, he was very inſtrumental in procuring Mr. Selden's valuable collection of books for the public library; he diſtinguiſhed himſelf by the correction of abuſes, and by the regulation of the public exerciſes in ſuch a manner, as proved highly beneficial to the intereſts of ſolid learning. By ſome of his biographers, Mr. Conant has been applauded for the ſhare which he took in defeating a project for erecting an univerſity in the county of Durham. Praiſe on this account to us ſeems very ill beſtowed, becauſe the intended object was worthy of a great nation, whoſe places of public inſtruction cannot be regarded as ſufficiently numerous, to ſuperſede the neceſſity of others in diſtant parts of the kingdom. Upon the reſtoration of Charles II. Dr. Conant, in his official capacity, came to London, attended by the proctors, and others, and being introduced to the king he made a Latin ſpeech on the occaſion, and preſented his majeſty with a book of verſes written by the members of the univerſity. He was appointed, in March 1661, a commiſſioner with others to review the book of common prayer, and he aſſiſted at the Savoy conferences. After this, upon the paſſing of the act of uniformity, he was deprived of his preferments, becauſe he refuſed to conform. During eight years he lived in retirement, when, upon ſerious deliberation on the nature and lawfulneſs of conformity, he reſolved to comply, and ſubmitted to a re-ordination by Reynolds, biſhop of Norwich, whoſe daughter he had married nearly twenty years before. Preferments were now immediately offered to his choice; and he accepted of the vicarage of All-Saints, Northampton, in which town he had for ſeveral years reſided, in the higheſt eſtimation of the moſt reſpectable inhabitants. In Sept. 1675, his church and the greater part of the pariſh were deſtroyed by fire; but his own houſe eſcaped. In the ſucceeding year the biſhop of Norwich offered him the archdeaconry, with this high compliment, "I do not expect thanks from you, but ſhall be very thankful to you, if you will accept of it." He conceded to this handſome requeſt, and diſcharged the office worthily, as long as his health would allow. In December 1681, he was inſtalled a prebendary in the church of Worceſter, at the requeſt of the earl of Radnor, who aſked for it of the king, ſaying he came to beg preferment for a very deſerving perſon, who never ſought any thing for himſelf. He had long laboured under a weakneſs of ſight, which terminated in total blindneſs in the year 1686. This heavy calamity, and the weight and infirmities of old age, he bore with exemplary reſignation to the divine will till his death, which happened March 12, 1693. He was interred in his own pariſh church of All-Saints in Northampton, where a handſome monument was erected to his memory. Dr. Conant was a man of ſolid and extenſive learning, but his great diffidence led him to conceal his acquirements. We have ſix volumes of his ſermons, of which one was dedicated by himſelf to the inhabitants of Northampton, the others were publiſhed after his death, by Dr. John Williams, afterwards biſhop of Chicheſter, and Mr. Coates principal of Magdalen-hall. Biog. Brit.

CONARIUM, in *Anatomy*, a term which has been applied to the pineal gland of the brain, in conſequence of its conical figure. See BRAIN.

CONATUS, *endeavour*, a term frequently uſed by philoſophical and mathematical writers; nearly equivalent to *niſus*. Conatus ſeems to be the ſame, with reſpect to motion, that a point is with reſpect to a line; at leaſt the two have this in common, that as the point is inceptive of the line, or the term from which it commences; ſo is the beginning of all motion called the *conatus*. Add, that as in mathematical demonſtrations, the extenſion of the point is conceived as if it were nothing at all; ſo, in the *conatus* of motion, there is no regard to the time wherein, or the length which, it advances. See *Laws of* NATURE.

Hence, ſome define conatus to be a quantity of motion not capable of being expreſſed by any time or length. Accordingly, all motion tends preciſely the ſame way wherein the moveable is acted on, or determined by the ſame moving power. See MOTION.

CONAWANGO, in *Geography*, a northern branch of Alleghany river, in Pennſylvania, which riſes from Chataughque lake.

CONCA, CAV. SEBASTIANO, in *Biography*, an hiſtorical painter of conſiderable reputation in the 18th century. He was born at Gaeta in the year 1676, and became the diſciple of F. Solemene, the moſt celebrated maſter of the ſchool of Naples at that period. At the age of forty, Conca eſtabliſhed himſelf at Rome, and ſpent five whole years in drawing from the fineſt productions of ancient and modern art, in the vain hope of uniting to the graceful facility he had acquired from his maſter, a greater purity and correctneſs of deſign. But it was too late; bred a manneriſt, he had inſenſibly imbibed thoſe maxims which were to decide his future character; and at length he had the good ſenſe to adopt the advice of the ſculptor Le Gros, by purſuing the track which had originally been pointed out to him. He ſoon became an able machiniſt *(pittore di macchina)*, in a ſtyle not very unlike that of Cortona. He united to facility of invention, and rapidity of pencil, a gay and faſcinating diſtribution of colour; but his fleſh has generally too green a hue in the ſhadows. Amongſt his large works at Rome, the "Aſſumption," at the church of St. Martino, and the "Prophet Jonas," at St. Giovanni Laterano, are of the beſt. Many of his other productions are at Loretto, Ancona, and other towns of the eccleſiaſtical ſtate, beſides an infinity of cabinet pictures diſperſed throughout all parts of Europe. This artiſt died in 1764. He had a brother, Giovanni Conca, who aſſiſted him in the execution of many of his large works, and is ſaid to have been an excellent copyiſt. Lanzi, Storia Pittorica.

CONCA, in *Geography*, a town of the iſland of Corſica, 12 miles N. of Porto Vecchio.—Alſo, a market town in a ſmall lake in the Campagna di Roma, in Italy.—Alſo, a ſmall

ſmall river of Italy, which has its ſource in the duchy of Urbino, and flows into the gulf of Venice.

Concale. See Cancale.

Concale *Bay*, in the channel, on the coaſt of the department of Ille and Vilaine in France, is a fine bay, in which the Engliſh effected a landing in June 1758, and whence they proceeded to the port of St. Malo, where they burnt above 100 veſſels of different ſizes.

CONCAMERATED, among *Builders*, an appellation given to ſuch roofs as are arched in the vaults.

CONCAMERATIO, was an arched room in our ancient churches, between the eaſt end of the church and the high altar; ſo formed, that in proceſſions they might ſurround it.

CONCAN, or Cockun, in *Geography*, a tract of country on the weſtern coaſt of Hindooſtan, ſituated between Bombay and Goa, and ſeparated from the reſt of the continent by a ridge of high mountains called the Gauts. When the Moguls ſeized on Hindooſtan, they found this coaſt infeſted with pirates, and fitted out a fleet to protect their veſſels. The Mahrattas, finding their piracies interrupted, armed againſt the Moguls, ravaged their poſſeſſions, and fitted out a fleet to protect their pirates. Conagy Angria, who by his courage had acquired the ſupreme command, was appointed governor of Severndroog, one of the beſt fortreſſes on the coaſt, where he formed an independent ſtate, and in a little time extended his dominions for the ſpace of 40 leagues along the coaſt, and ſix leagues wide towards the mountains. His ſucceſſors aſſumed the name of Angria, and made peace with the Mahrattas on paying an annual tribute. They continued to make depredations on the coaſt, and ſeize all veſſels that paſſed that way till the year 1756, when their fleet was deſtroyed, and the ſtrong fort of Gheriah, in which the chief reſided, was taken by admiral Watſon and colonel Clive. The country now belongs to the Mahrattas. The principal towns are Choul, Fort Victoria, Dabul, Severndroog, Gheriah, Tamana, and Sunderdoo.

CONCANA, in *Ancient Geography*, a town of Spain, towards the north-eaſt of Lucus Aſturum, and to the ſouth of Salia, near the ſea. Horace ſays, that the inhabitants of this city took pleaſure in drinking the blood of horſes: and although a change took place in the manners of the people in Spain under the dominion of the Romans, Silius Italicus, who wrote under Trajan, gives an account of them ſimilar to that of Horace.

CONCANGIUM, a Roman ſtation, under the government of the honourable the duke of Britain, not mentioned in the Itinerary, but recorded in the Notitia Imperii, and generally believed to have been ſituated at Watercrook, near Kendal, where are viſible remains of a Roman ſtation, and where Roman antiquities have been found.

CONCARNEAU, or Conquerneau, in *Geography*, a ſmall, but neat ſea-port town of France, in the department of Finiſtere, and chief place of a canton in the diſtrict of Quimper, 42 miles S.E. of Breſt. The place contains 2,200, and the canton 6,320 inhabitants; the territory includes 125 kiliometres, and 4 communes. Its principal and almoſt only trade, is in pilchards, of which the average annual ſhipment is 600 barrels. The price of a barrel varies from 150 to 300 livres. N. lat. 47° 55′. E. long. 3° 45′.

CONCATENATION, in *Philoſophy*, a connexion of things, in manner of a chain.

The concatenation of ſecond cauſes is an effect of Providence. See Cause.

CONCAVE is applied to the inner ſurface of a hollow body; particularly if it be circular.

Concave is particularly underſtood of mirrors and lenſes: concave lenſes are either concave on both ſides, called *concavo-concave*; or concave on one ſide, and plane on the other, called *plano-concave*; or concave on one ſide, and convex on the other, called *concavo convex*, or *convexo-concave*, as the one or the other ſurface is a portion of a leſs ſphere.

The property of all concave lenſes is, that the rays of light, in paſſing through them, are deflected, or made to recede from one another; as in convex lenſes they are inflected towards each other; and that the more, as the concavity and convexity pertain to leſs circles.

Hence, parallel rays, as thoſe from the ſun, by paſſing through a concave lens, become diverging; diverging rays are made to diverge the more, and converging rays are either made to converge leſs, or become parallel, or go out diverging.

Hence, objects viewed through concave lenſes appear diminiſhed; and the more ſo, as they are portions of leſs ſpheres; and this in oblique, as well as in direct rays. See Lens.

Concave mirrors have the contrary effect to lenſes: they reflect the rays which fall on them, ſo as to make them approach more to, or recede from, each other than before, according to the ſituation of the object; and that the more as the concavity is greater, or the ſpheres whereof they are ſegments, leſs.

Hence, concave mirrors magnify objects preſented to them; and that in a greater proportion, as they are portions of greater ſpheres. See Mirror.

Hence, alſo, concave mirrors have the effect of burning objects, when placed in their focus. See Burning-glass.

CONCAVITY. An arch of a curve has its concavity turned one way, when the right lines that join any two of its points are all on the ſame ſide of the arch.

Archimedes, intending to include ſuch lines as have rectilinear parts, in his definition, ſays, a line has its concavity turned one way, when the right lines that join any two of its points are either all upon one ſide of it, or while ſome fall upon the line itſelf, none fall upon the oppoſite ſide. Archim. de Sphær. and Cyl. Def. 2. Mac Laurin's Fluxions, art. 180.

When two lines, having their concavity turned the ſame way, have the ſame terms, and the one includes the other, or has its concavity towards it, the perimeter of that which includes, is greater than the perimeter of that which is included. Archim. ib. ax. 2.

CONCEALERS, in *Law*, ſuch as find out concealed lands, *i. e.* lands kept privily from the king, by common perſons, having nothing to ſhew for their title, or eſtate therein.

They are thus called *per antiphraſin, a concelando*; as *mons* is *a movendo*, &c. Lord Coke calls them *turbidum hominum genus*.

CONCEALMENT *of baſtard's death*. See Bastard.

Concealment *of Treaſon*. See Misprision.

CONCELHO de Anciaens, in *Geography*, a town of Portugal, in the province of Tra-los-Montes, 8 miles W.N.W. of Mirandela.

Concelho *de Jaes*, a town of Portugal, in the province of Tra-los-Montes, 10 miles W.S.W. of Mirandela.

CONCELLANA, a town of Naples, in the province of Baſilicata; 5 miles S. of Acerenza.

CONCENTEYNA, a town of Spain, in the province of Valencia; 25 miles N. of Alicant.

CONCENTRATION, in general, denotes the retiring, or withdrawing of a thing inwards, towards the centre, or middle.

External cold is ſaid to concentrate the heat within bodies: after meals, the natural warmth retires, and as it were concentrates to promote the digeſtion.

Concentration is alſo uſed by Dr. Grew for the higheſt degree of mixture, *viz.* that wherein two or more atoms or particles touch, by a reception, and intruſion of the one within the other. See Mixtion.

This he takes to be the caſe of all fixed bodies without taſte or ſmell; their conſtitution being ſo firm, that till the particles be detached from each other by ſome extraordinary means, they cannot affect thoſe ſenſes.

Concentration, in *Chemiſtry*, the act of increaſing the ſtrength of fluids, which are rendered ſtronger by abſtracting a portion of the mere menſtruum. This is generally effected by evaporation, where the menſtruum is driven off at a lower heat than is required to drive off the ſubſtance with which it is united. Thus, dilute ſulphuric acid may be conſidered as a mixture of the real acid with water, and by applying a certain heat, the water may be evaporized, leaving the acid behind in a ſtate of concentration. When concentrated as much as poſſible, its ſpecific gravity is about twice as great as that of water, but it can rarely be obtained denſer than 1,85. When concentrated to 2,000 it contains a conſiderable portion of water, as has been proved by combining it with barytes or potaſh, in which caſe water remains behind, and does not enter into the combination. Again, vinegar conſiſts of an acid and water, and brandy of alcohol and water, and in proportion as the acid and alcohol are freed from the water, they are ſaid to be more or leſs concentrated. This may be performed, 1. Either by ſimple diſtillation, in which caſe the acid or ſpirit comes over firſt, leaving the water behind; or, 2. By expoſing the vinegar or brandy to ſevere froſt, when the water will be frozen, and the acid or alcohol will be found in a ſtate of concentration in the middle of the ice; the greater the cold, the higher the ſtate of concentration; M. Lowitz has found, that the acid, however concentrated, congeals at—22°. Sulphuric acid, on the other hand, expoſed to a much leſs ſevere cold, cryſtallizes, and to effect this, it muſt not be greatly concentrated. 3. Another mode of concentrating the acetic acid, is by diſtilling acetate of copper, reduced to powder, in a retort; at firſt there comes over a liquid nearly colourleſs, and almoſt inſipid, and afterwards a highly concentrated acid tinged with green; but being diſtilled a ſecond time in a moderate heat, it is colourleſs, tranſparent, exceedingly pungent and concentrated. 4. The moſt perfect method of obtaining this acid in a concentrated ſtate, was diſcovered by M. Lowitz of Peterſburg; it is thus: diſtil a mixture of three parts of acetate of potaſh, and four parts of ſulphuric acid, till the acetic acid has come over into the receiver. To ſeparate it from the ſulphuric acid, with which it is ſlightly contaminated, it muſt be diſtilled over a portion of acetate of barytes. By the experiments of Adet, Darracq, and others, on concentrating the acetic and acetous acids, it is aſcertained that they differ only in concentration, each containing preciſely the ſame proportion of oxygen. Concentrated acetic acid is capable of an acceſs of oxygen, and in that ſtate it is called oxygenated acetic acid. Sulphuric and nitric acids, whether diluted or concentrated, are ſtill the ſame ſulphuric and nitric acids; but ſulphur*ic*, and ſulphur*ous*, or nitr*ic* and nitr*ous* acids, whatever be the ſtate of concentration, have different properties, and are of courſe ſpecifically different acids. Elem. de Chymie. Thompſon's Chemiſtry, Gren's Principles.

Concentration, in *Diſtillery*. Dr. Shaw, in his "Eſſay on the Diſtillery," is for introducing a method of concentrating the fermentable parts of vegetables from which their ſpirits are to be drawn by diſtillation; which, if it can be brought to be practiſed in the large way, will prove of very great uſe to the Britiſh diſtillery, as it will greatly ſhorten the diſtiller's buſineſs; which, at preſent, including the brewing, fermenting, &c. is much too long. He propoſes only to evaporate carefully the wort, or other tinctures or decoctions of vegetables made for the diſtilling of their ſpirits, to the conſiſtence of treacle: in this form they might be ſold to the diſtiller, who might keep them by him as long as he pleaſed, and occaſionally uſe them, by the eaſy method of reducing them into wort, by mixing warm water with them.

CONCENTRIC, in *Geometry* and *Aſtronomy*, ſomething that has the ſame common centre with another.

The word is principally uſed in ſpeaking of round bodies and figures, *viz.* circular, elliptical ones, &c. but may be likewiſe uſed for polygons, drawn parallel to each other, upon the ſame centre.

Concentric ſtands oppoſite to excentric.

To find the area of the ſpace included between the circumferences of two concentric circles; ſee Annulus.

Nonius's method of graduating inſtruments, conſiſts in deſcribing with the ſame quadrant 45 concentric arches, dividing the outermoſt into 90 equal parts, the next into 89, &c. See Nonius.

CONCENTRICITY *of the Strata*, in *Natural Hiſtory*. The idea has very generally prevailed among geologiſts and mineralogical writers, that the ſeveral layers of matter or ſtrata, which compoſe the ſurface of the earth we inhabit, were originally formed or depoſited in uniform and level beds, or concentric to the centre or maſs of the earth. Among theſe Mr. Whitehurſt, in his "Enquiry into the Original State and Formation of the Earth," 1ſt edit. p. 192, ſays, the ſtrata "obtained an uniform concentric arrangement, ſurrounding the centre of the earth, as ſo many ſhells may be ſuppoſed to ſurround an egg." And nearly ſimilar have been the opinions of a large portion of writers on this ſubject. Mr. Kirwan, "Geological Eſſays," p. 22, ſuppoſes, that the cryſtallization of ſtrata from the chaotic or polygenous fluid, in ſome caſes, began at the ſurface, as we ſee happen to ſome ſalts and to lime water under evaporation, and that thus extenſive ſtrata might have been formed and ſunk to the bottom, moſtly in an horizontal poſition, but often from accidental ruptures during their fall, in an oblique or nearly vertical poſition. Dr. Townſon, "Philoſophy of Mineralogy," p. 68, ſays, "we muſt not ſuppoſe that the ſtrata regularly ſurround the globe like the concentric circles of an onion; they are rather like the ſcales of a lily; rather *ſquamoſus* than *tunicatus*. Though, in general, they are of great extent when not broken and loſt, they are known to have a natural termination." In the "Philoſophical Tranſactions," No. 391, Mr. John Stracey gives a figure for explaining a ſuppoſition of his on this ſubject, *viz.* that the ſtrata were originally formed while in a ſoft ſtate, as ſo many wedges, each pointing to and terminating in the axis of the earth; and that by the diurnal revolution of the earth from weſt to eaſt, theſe became bent into ſpirals, each lapping round each other, for ſome diſtance, and then ending, in ſucceſſion.

Whimſical as this laſt idea muſt have appeared, when it was firſt publiſhed, now more than 80 years ago, we are ſomewhat ſurprized that it had not the effect of occaſioning ſubſequent geological obſervers to notice, more particularly, the endings of the ſtrata, and the remarkable prevalence of their dip towards the ſouth-eaſt, compared with thoſe in any other direction; eſpecially when practical miners muſt have ſo often mentioned the dip "towards the 10 o'clock ſun," as being the moſt common. Under the articles Coal, and Colliery, the writer of this has endeavoured to ſhew that the ſtrata of the Britiſh iſlands end in ſucceſſion in proceeding from the ſouth-eaſtern part of England towards the north-weſt; the general dip being towards the ſouth-eaſt or nearly ſo, except in immenſely diſlocated parts of the country, as the wealds of Suſſex, Kent, and Surry, the peak of Derbyſhire and Staffordſhire, &c. of which ſome further and curious particulars will be given under the articles Denudation, Elevation, and Endings *of Strata*. From all which, it is expected that it will be made evidently to appear, that the ſtrata were not originally concentric with the earth's centre, but that the ſame formed planes or zones, inclined eaſtward in a ſmall angle with the horizon, which were of amazing extent, and were perfectly regular in their poſition, before they experienced the rude and almoſt inconceivable violence, which broke and tore the earth in pieces, and left it in its preſent form.

CONCEPTACULUM, in *Botany*, was originally applied by Linnæus to that kind of ſeed-veſſel which he afterwards termed *folliculus*, and which conſiſts of one valve only, burſting longitudinally, as in the natural order of *aſclepiadeæ*. Gærtner uſes the term *conceptaculum* in a general and lax ſenſe for a ſeed-veſſel, nor is it at preſent technically applied to any particular kind of fruit.

CONCEPTION, in *Geography*, otherwiſe called *Penco*, a city of Chili, in South America, and capital of a juriſdiction or biſhopric, ſuffragan of the archbiſhop of Lima, and having a chapter, conſiſting of a biſhop, dean, archdeacon, and two prebendaries. The ancient city ſtood at the mouth of the river St. Pierre, E. of Talcaguana, on the S.W. ſhore of a beautiful bay, and on a ſmall declivity, having a little river running through it, in S. lat. 36° 43′ 15″, and in longitude from the meridian of Teneriff, according to Father Feuillée, 303° 18′ 30″. The houſes were built with mud or burnt bricks, and covered with tiles; the churches, and alſo the Franciſcan, Auguſtine, and Dominican convents, as well as thoſe belonging to the fathers of mercy, were ſmall and mean, but the college of the Jeſuits was conſtructed in a ſuperior ſtyle of architecture. This city was firſt founded by captain Pedro de Valdivia in the year 1550; but the powerful revolt of the Indians of Arauco and Tucapel, obliged its inhabitants to remove to Santiago. Pedro de Valdivia, its founder, was killed in this conteſt, and his ſucceſſor in the command ſhared the ſame fate. The inhabitants, however, petitioned the audience of Lima for leave to return to their original city; they were again either ſlain or diſpoſſeſſed by the Indians; but thoſe that ſurvived were afterwards reſtored to their former poſſeſſion, which they for ſome time continued to enjoy with apparent ſecurity. In 1603 a more general confederacy was formed againſt the city, by which it was almoſt wholly deſtroyed; but receiving freſh ſuccours, it was again repaired. Subject, however, to dreadful earthquakes, and conſiſting of buildings ill adapted for permanent duration; it was totally deſtroyed by an earthquake in 1751 and nothing but its ruins are now viſible on the ſpot where it once ſtood. After the deſtruction of this town, which, during the earthquake, was ſwallowed up rather by the ſea than by the land, the inhabitants diſperſed and encamped in the environs. In 1763 they ſelected another ſpot, ſituated about a quarter of a league from the river Biobio, and three leagues from the ancient town of Conception, and the village of Talcaguana. On this ſpot they erected a new town, to which the biſhopric, the cathedral, and the religious houſes were transferred. The houſes conſiſt only of one ſtory, that they may be able more effectually to reſiſt the ſhock of earthquakes, which occur in thoſe parts almoſt evey year. This town occupies a large extent of ground. The inhabitants are about 10,000; and here is the reſidence of the biſhop and a colonel of horſe, who is the military governor. The biſhopric is nominally bounded on the north by that of Santiago, the capital of Chili, where the governor-general reſides, and on the eaſt by the Cordilleras, and extending on the ſouth as far as the ſtraits of Magellan. But its true limit is the river Biobio, about a quarter of a league from the town. M. de la Perouſe ſays of this part of Chili, that it is the moſt fertile ſpot in the world. Corn, he ſays, produces ſixty-fold, and the vine is equally abundant; the fields are covered with innumerable flocks, which, without requiring any care, multiply beyond all calculation. The only care neceſſary is to keep ſeparate the different property of individuals; and oxen, horſes, mules, and ſheep herd together in the ſame paſtures. A large ox is commonly worth eight dollars, a ſheep ¾ of a dollar; but there are no purchaſers, ſo that the inhabitants kill every year a great quantity of cattle, the ſkins and tallow of which are ſent to Lima. They alſo cure ſome proviſions for the conſumption of the ſmall coaſting veſſels which navigate the ſouth ſeas. The climate is remarkably healthy, and M. Pérouſe found ſeveral in this town that had completed 100 years; but notwithſtanding all theſe advantages, the colony is not thriving, which he attributes principally to the prohibitory regulations that extend through every part of Chili. This kingdom, he ſays, of which the productions, increaſed to their maximum, would ſupply all Europe; whoſe wool would be ſufficient for the manufacture of France and England, and whoſe herds, converted into ſalt proviſion, would produce a vaſt revenue; has no commerce. Four or five ſmall veſſels bring every year from Lima tobacco, ſugar, and ſome articles of European manufacture, which the miſerable inhabitants receive after having been charged with heavy cuſtoms at Cadiz, at Lima, and, laſtly, at their arrival at Chili; in exchange for which they give their tallow, hides, ſome deals, and their wheat, which, however, bears ſo low a price, that the cultivator has no inducement to extend his tillage. Unfortunately, ſays Pérouſe, for this country, it produces a ſmall quantity of gold; the annual amount of which in the dioceſe of Conception is eſtimated at about 200,000 piaſtres. The adminiſtration of juſtice is very defective. To theſe ſeveral circumſtances it is owing that the land remains uncleared, that commerce is in a low ſtate, that the houſes of the moſt opulent inhabitants of La Conception are almoſt deſtitute of furniture, and that the only workmen in the town are foreigners. The dreſs of the women conſiſts of a plaited petticoat, diſcovering half the leg, formed of gold and ſilver ſtuffs, which, being reſerved for extraordinary occaſions, is transferred, like jewels, from grand-mother to grand-daughter, ſtriped ſtockings of red, blue, and white, and very ſhort ſhoes, but ſuch ornaments are only within the reach of a few; the reſt having ſcarcely clothes to cover their nakedneſs. The idleneſs, together with the credulity and ſuperſtition of the inhabitants, has filled this kingdom with convents, both for men and women. The common people are a mongrel race, much addicted to theft, and the women are very eaſy of acceſs. Nevertheleſs, thoſe of a ſuperior claſs, or the true Spaniards, are extremely polite, and hoſpitable. The inhabitants, and even the women, excel in horſemanſhip; they are very dextrous in managing the lance and nooſe; and they rarely miſs their aim, though at full ſpeed, with the nooſe, which they throw 40 or 50 yards, and thus halter the object of their diverſion or revenge. The nooſe is made of thongs of cow-hides, which they twiſt with oil, till it is rendered ſupple and pliant, and ſo ſtrong ,as to hold, it is ſaid, a wild bull which would break a halter of hemp of double thickneſs. De Ulloa's, &c. Voyage to South America, vol. i. Perouſe's Voyage round the World, vol. i.

Conception, *the bay of,* is one of the moſt commodious that can be found in any part of the world. The length from Terra-firma, N. and S. is nearly 3½ leagues, and its breadth from E. to W. almoſt 3 leagues, which is contracted by the iſland of Quiriquina, forming two entrances; of theſe, that on the eaſt ſide is the ſafeſt, being two miles broad, and accordingly frequented by moſt ſhips. The weſt entrance is between the iſland and Talcaguana point, and is near half a league in breadth. In the principal entrance of this bay is 30 fathom water, which depth afterwards decreaſes to 11 and 10, till within about a mile of the ſhore, oppoſite to the entrance. The weſtern entrance, though the numerous rocks and breakers in it make it to appear very dangerous, has a channel with water ſufficient for the largeſt ſhip, the depth being at firſt 30 fathom, and never leſs than eleven. Within the bay are three roads or harbours, where ſhips anchor; for though the bottom be every where clear, it is only in one of theſe three places that ſhips can ride in ſafety, being no where elſe ſheltered from the wind. The firſt, called Puerto Tome, lies eaſt and weſt, with the north point of Quiriquina, contiguous to the coaſt of Terra-firma. The anchoring place is about half a league diſtant from the land; in about 12 fathom water. But this road is uſed only when the ſhips come in during the night; it being difficult to reach either of the other two before day-light, as ſeveral tacks muſt be made for that purpoſe. In this bay the principal port is that of Talcaguana. It is properly an elbow, and bears S. S.W. from the ſouth point of Quiriquina. This is much the moſt frequented, ſhips in general anchoring here, as it has not only better ground than any other part of the bay, but is moſt ſheltered from the north winds. Whereas at Cirillo Verde, a little green mountain, ſituated near the city, they lie expoſed not only to theſe winds, but alſo to the ſouth winds; the land which ſhould intercept them being low. Beſides, the bottom is of a looſe mud, ſo that the anchors in a hard gale of wind generally come home; and conſequently the ſhips are in great danger of being ſtranded on the coaſt. From theſe inconveniences it may be concluded, that the only ſhips which anchor here are ſuch as happen to be in theſe parts in the midſt of ſummer, for which this road is moſt convenient, as it is neareſt to the city. Although the tide riſes in this bay ſix feet three inches, the water is ſmooth, and there is ſcarcely any current. It is high water here at the full and change of the moon, at 45 minutes paſt one. The bay is open only to the north winds, which never blow but in the winter, that is, from the end of May to October. Two rivers empty themſelves into this bay; one of which paſſing through the city of Conception bears its name; the other is called St. Pedro. The firſt is the watering place for ſhips anchoring at Cirillo Verde; whereas thoſe at Talcaguana ſupply themſelves from ſtreams that flow from the adjacent eminences; they eaſily take on board a ſufficient quantity of wood, of which there is plenty, and alſo of all other neceſſaries. Ships, before they enter the bay of Conception, endeavour to make the iſland of Santa Maria, and then coaſt along it keeping at the ſame time a good look out for a reef of rocks which ſtretches out almoſt three leagues from the north-weſt point; thence they continue their courſe, keeping at a little diſtance from the main, there being no rocks beſides thoſe that are above the water. After weathering the rocks on the iſland of Santa Maria, they ſteer directly for Talcaguana point, at the diſtance of about half a league; from which ſea-ward is a rock called Quiebra-ollas, which ſhould be carefully avoided, as it is ſurrounded with ſhoals. After being abreaſt of this rock, they ſteer for the north point of Quiriquina; off which lie two rocks ſwarming with ſea-wolves; but as there is a ſufficient depth of water all round them, there is no other danger in ſtanding near them beſides that which is viſible. After paſſing them, the courſe is continued as near as poſſible to the iſland of Quiriquina, care being taken to avoid ſome other rocks lying along the ſhore. In making ſeveral tacks to get into Conception-bay, the iſland of Quiriquina muſt be avoided on the eaſt and ſouth ſides, as there is a ſhoal on the ſouth extending to a conſiderable diſtance from the ſhore. At a third part of the diſtance between the road at Talcaguana, and the point of the ſame name, is another ſhoal, running about half a league towards the eaſt, in the middle of which is a ridge of rocks. To avoid this ſhoal, it is beſt at entering the bay with a land wind, to ſteer directly for the middle of a ſpot of red earth on a mountain of middling height, ſituated at the bottom of the bay, continuing this courſe till the ſhip has paſſed the ſhoal; and then to ſteer directly for the houſes at Talcaguana, till within about half a mile from the ſhore, which is the uſual anchoring place in 5 or 6 fathom water. The ſame care is alſo neceſſary to avoid another reef of rocks, lying between the Morro and the coaſt of Talcaguana.

Conception, or *Conception de los Pampas,* a town of South America, in Paraguay, on the S. ſide of the river Plata. S. lat. 36° 30′. W. long. 57° 11′.

Conception, *La,* a ſea-port town of America, in the province of Veragua, on the Spaniſh main, with a harbour, formed by the river Veragua; 90 miles W. of Panama. N. lat. 8° 52′. W. long. 81° 51′.

Conception, a river of America, on the iſthmus of Darien, which runs into the Spaniſh main. N. lat. 9° 4′. W. long. 78° 15′.

Conception *Bay,* a large bay on the eaſt coaſt of Newfoundland iſland, whoſe entrance is between Cape St. Francis on the ſouthward, and Flamborough head on the northward. It runs a great way into the land in a ſouthern direction, having numerous bays on the W. ſide, in which are two ſettlements, Carboniere and Havre de Grace. Settlements were made here in 1610, by about 40 planters, under governor John Guy, to whom king James had granted a patent of incorporation. N. lat. 47° 40′. W. long. 52° 40′.

Conception *de Salava,* or *of Salaye,* a ſmall town of North America, in the province of Mechoacan, in Mexico. It was built by the Spaniards, as well as the ſtations of St. Michael and St. Philip, to ſecure the road from Mechoacan to the ſilver mines of Zacatea. N. lat. 10°. W. long. 83° 5′. They have alſo given this name to ſeveral boroughs of America, to a ſea-port of California, &c. &c.

Conception *de la Vega,* a town of Hayti, in what was formerly the Spaniſh part of Hiſpaniola, or St. Domingo. It gave the title of duke to the family of Columbus, the immortal diſcoverer of America.

Conception, in *Grammar.* See Syllepsis.

CONCEPTION, in *Logic* and *Metaphyſics*, the ſimple apprehenſion or perception which we have of any thing, without proceeding to affirm or deny any thing about it.

The ſchoolmen uſually make two kinds of conception; the one formal, the other objective.

The firſt is defined to be the immediate and actual repreſentation of any thing propoſed to the mind: on which footing, it ſhould be the ſame thing to the underſtanding, that a word or voice is to the ear; whence ſome alſo call it *verbum mentis*.

The ſecond is the thing itſelf repreſented by a formal conception. But others explode the notion of an objective conception, as being, in reality, no conception at all; excepting where the mind contemplates its own acts, &c.

Formal or proper conceptions, are ſubdivided into univocal, where ſeveral things are diſtinctly repreſented as under ſome common ratio, or in the ſame degree of perfection; analogous, where ſeveral things are repreſented as under ſome proportional likeneſs; and equivocal, where they are repreſented immediately as ſuch, without regard to any common ratio or likeneſs.

Dr. Reid, in his "Inquiry into the Human Mind, on the Principles of Common Senſe," and alſo in his "Eſſays on the Intellectual Powers of Man," (Eſſ. iv.), ſubſtitutes the word conception inſtead of the ſimple apprehenſion of the ſchools, and employs it in the ſame extenſive ſignification. He alſo uſes it, in common with ſome other writers, as ſynonymous with *Imagination*, which ſee. To this purpoſe, he ſays, that "conceiving, imagining, apprehending, underſtanding, and having a notion of a thing, are common words to expreſs that operation of the underſtanding, which the logicians call "*Simple* APPREHENSION;" which is defined by them to be the bare conception of a thing without any judgment or belief about it. However, although conception may be exerciſed without any degree of belief, even the ſmalleſt belief cannot take place without conception; for he who believes muſt have ſome conception of the object of his belief. Dr. Reid, without attempting a definition of this operation of the mind, explains ſome of its properties, ſtates different theories concerning it, and points out ſome miſtakes of philoſophers in their account of it. In every operation of the mind, ſays this writer, and in every thing which we call thought, there muſt be conception. Our ſenſes cannot give us the belief of any object, nor can we remember or reaſon, nor exert any of our active powers, without this mental operation; but in bare conception, there can, he thinks, be neither truth nor falſehood, becauſe it neither affirms nor denies. In this reſpect, conception differs from opinion; as an opinion, though ever ſo wavering, or ever ſo modeſtly expreſſed, muſt be either true or falſe; whereas a bare conception, which expreſſes no opinion or judgment, can be neither; to this purpoſe, Mr. Locke obſerves very juſtly, if we ſubſtitute conceptions for ideas, that our ideas, being nothing but bare appearances, or perceptions, in our minds, cannot properly and ſimply in themſelves be ſaid to be true or falſe, no more than a ſimple name of any thing can be ſaid to be true or falſe. Mr. Locke, following the example of Des Cartes, Gaſſendi, and other Carteſians, has given the name of perception to the bare conception of things; and he has been followed in this reſpect by biſhop Berkeley, Mr. Hume, and many late philoſophers, when they are diſcuſſing the ſubject of ideas. They have been probably led into this impropriety, ſays Dr. Reid, by the common doctrine concerning ideas, which teaches us, that conception, perception by the ſenſes, and memory, are only different ways of perceiving ideas in our own minds; and if that doctrine be well founded, he thinks that it will be very difficult to find any ſpecific diſtinction between conception and perception. He adds, there is reaſon to diſtruſt any philoſophical theory, when it leads men to corrupt language, and to confound, under one name, operations of the mind, which common ſenſe and common language teach them to diſtinguiſh. This author further obſerves, when he is tracing the analogies that ſubſiſt between the operations of body and thoſe of the mind in the plaſtic arts, and particularly in painting, that nothing more readily gives the conception of a thing than the ſeeing of an image of it; and hence, by a figure common in language, conception is called an image of the thing conceived. Nevertheleſs, the image in the mind is not the object of conception, nor is it any effect produced by conception as a cauſe, but it is conception itſelf. In this mode of illuſtrating conception, Dr. Reid differs from many other philoſophers, who have generally maintained, that in conception there is a real image in the mind, which is its immediate object, and diſtinct from the act of conceiving it. This author proceeds to trace the analogy that ſubſiſts, not only between conceiving and painting in general, but between the different kinds of our conceptions, and the different works of the painter. As this artiſt makes fancy-pictures, or copies from the painting of others, or paints from the life, that is, from real objects of art or nature which he has ſeen, our conceptions, in Dr. Reid's opinion, admit of a very ſimilar diviſion. Some conceptions may be called fancy-pictures, being commonly called creatures of fancy or of imagination, which are not the copies of any original that exiſt, but are originals themſelves. There are other conceptions, which may be called copies, becauſe they have no original or archetype, to which they refer, and with which they are believed to agree; and we call them true or falſe conceptions, as they agree or diſagree with the ſtandard to which they are referred. Theſe are of two kinds, *viz.* ſuch as are analogous to pictures taken from the life, or ſuch a we have of individual things that really exiſt; and ſuch as are analogous to the copies which the painter makes from pictures done before, which are the conceptions we have of what the ancients called univerſals, or of things which belong or may belong to many individuals. Theſe univerſals are always expreſſed by general words; and all the words of language, proper names excepted, are general words, or the ſigns of general conceptions, or of ſome circumſtances relating to them. Such general conceptions are formed for the purpoſe of language and reaſoning.

Having thus ſtated the three different kinds of our conceptions, and illuſtrated them at large, our author proceeds to deſcribe their different properties. Accordingly he obſerves, that our conception of things may be ſtrong and lively, or it may be faint and languid in all degrees. In this connection it is ſaid, that imagination, when it is diſtinguiſhed from conception, ſeems to ſignify one ſpecies of conception, *viz.* the conception of viſible objects. Again, our conceptions of things may be clear, diſtinct, and ſteady; or they may be obſcure, indiſtinct, and wavering. Moreover, when we barely conceive any object, the ingredients of that conception muſt either be things with which we were before acquainted by ſome other original power of the mind, or they muſt be parts or attributes of ſuch things Thus, a man cannot conceive colours, if he never ſaw, nor ſounds, if he never heard. If man has not a conſcience, he could not conceive what is meant by moral obligation, or by right and wrong in conduct. Nevertheleſs, we are unconfined with regard to the arrangement of the ingredients of our conception; and this laſt property of the faculty of conception, and that which eſſentially diſtinguiſhes it from every other power of the mind, is this, that it is not employed ſolely about things which have exiſtence.

The powers of ſenſation, of perception, of memory, and of conſciouſneſs, are all employed ſolely about objects that [illegible]; but conception is often employed about objects [illegible]ther do, nor did, nor will exiſt. To prevent imp[illegible]n in this matter, we ought to diſtinguiſh between that act or operation of the mind, which we call conceiving an object, and the object which we conceive. [illegible]ceive any thing, there is a real act or opera[illegible] mind; of this we are conſcious, and can have [illegible]ce; but every ſuch act muſt have an [illegible] conceives muſt conceive ſomething. For th[illegible] of conception ſtated by Dr. Reid, [illegible] upon them, we muſt refer to the ar[illegible] cloſes his account of the faculty of conception with an enumeration of what he conceives to be the errors into which writers have fallen in their diſcuſſion of the operations of the mind. In all judgment and in all reaſoning, he ſays, conception is included. We can neither judge of a propoſition, nor reaſon about it, unleſs we conceive or apprehend it; and therefore thoſe are miſtaken who ſo diſtinguiſh between conception, judgment, and reaſoning, as to imply, that a propoſition, or even a ſyllogiſm, may not be ſimply apprehended. Dr. Reid further obſerves, that the diviſion, commonly made by logicians, of ſimple apprehenſion into ſenſation, imagination, and pure intellection, ſeems to be, in ſeveral reſpects, very improper. Senſation, and the perception of external objects by the ſenſes, are, in his opinion, very different operations of the mind; and, though commonly conjoined by nature, they ought to be diſtinguiſhed by philoſophers. Neither ſenſation, nor the perception of external objects, is ſimple apprehenſion; becauſe both, as he thinks, include judgment and belief, which are excluded from ſimple apprehenſion. Moreover, thoſe who diſtinguiſh imagination from pure intellection, by referring to the imagination an image in the brain, and to pure intellection an image in the intellect, ground their diſtinction upon an hypotheſis; ſince we have no evidence, as he apprehends, that there are images either in the brain, or in the intellect. See Imagination. Dr. Reid further obſerves, that it is a miſtake to repreſent ſimple apprehenſion as the firſt operation of the underſtanding, and judgment as a compoſition or combination of ſimple apprehenſions, which miſtake probably has ariſen from ſuppoſing that ſenſation and the perception of objects by the ſenſes, are nothing but ſimple apprehenſion. Although theſe are very probably the firſt operations of the mind, they are not ſimple apprehenſions. See Perception. Inſtead of ſaying, that the more complex operations of the mind are formed by compounding ſimple apprehenſions, we ought rather to ſay, that ſimple apprehenſions are obtained by analyſing more complex operations. In this connection, Dr. Reid obſerves, that a ſimilar miſtake pervades the whole of Mr. Locke's Eſſay. It is this, that our ſimpleſt ideas or conceptions are got immediately by the ſenſes, or by conſciouſneſs; and the complex afterwards formed by compounding them. He notices alſo another miſtake concerning conception, which is, that our conception of things is a teſt of their poſſibility; ſo that, what we can diſtinctly conceive, we may conclude to be poſſible; and of what is impoſſible, we can have no conception. This opinion has been held by philoſophers for more than 100 years, without contradiction or diſſent, as Dr. Reid believes; and he conſiders it as a neceſſary conſequence of the received doctrine of ideas; ſince it is evident, that there can be no diſtinct image, either in the mind, or any where elſe, of that which is impoſſible. Our author has inveſtigated this opinion, and urged a variety of objections againſt it. Whatever, he ſays, is declared to be poſſible or impoſſible is expreſſed by a propoſition; and every propoſition, of which you underſtand the meaning diſtinctly, is poſſible. Farther, every propoſition, that is neceſſarily true, ſtands oppoſed to a contradictory propoſition that is impoſſible; and he that conceives one, conceives both: thus, a man who believes that two and three neceſſarily make five, muſt believe it to be impoſſible that two and three ſhould not make five. Again, mathematicians have, in many caſes, proved ſome things to be poſſible, and others to be impoſſible; which, without demonſtration, would not have been believed; "yet I have never found," ſays Dr. Reid, "that any mathematician has attempted to prove a thing to be poſſible, becauſe it can be conceived, or impoſſible, becauſe it cannot be conceived." Moreover, mathematicians often require us to conceive things that are impoſſible, in order to prove them to be ſo; and this is the caſe in all their demonſtrations, "ad abſurdum." For other particulars connected with the ſubject of this article, and a fuller view of Dr. Reid's illuſtration and reaſoning, we muſt refer to his Eſſays above cited.

A late excellent writer, to whom thoſe who wiſh to underſtand the philoſophy of the human mind are under great obligation, though they may not admit all his principles and reaſoning, has particularly conſidered the power of conception. By conception profeſſor Dugald Stewart (ſee his "Elements of the Philoſophy of the Human Mind," ch. iii.) means, that power of the mind which enables it to form a notion of an abſent object of perception, or of a ſenſation which it has formerly felt. Although this is not excluſively the proper meaning of the word, yet he thinks that the faculty now defined deſerves to be diſtinguiſhed by an appropriated name. Conception is often confounded with other powers: memory recognizes the features of an abſent or deceaſed friend, and every act of this faculty includes an idea of the paſt; whereas conception implies no idea of time whatever. Thus conſidered, the word conception correſponds to what was called by the ſchoolmen *ſimple apprehenſion*; with this difference only, that they included, under this name, our apprehenſion of general propoſitions; whereas the profeſſor wiſhes to limit the application of the word *conception* to our ſenſations, and the objects of our perceptions. By thus reſtricting the application of the term, more than Dr. Reid has done, our ideas become more diſtinct; and for ſuch a reſtriction the authority of philoſophers in an analogous caſe may be juſtly pleaded. In ordinary language, we apply the ſame word *perception* to the knowledge which we have by our ſenſes of external objects, and to our knowledge of ſpeculative truth; and yet an author would be juſtly cenſured, who ſhould treat of theſe two operations of the mind under the ſame article of perception. "Thus," ſays the profeſſor, "there is as wide difference between the conception of a truth, and the conception of an abſent object of ſenſe, as between the perception of a tree, and the perception of a mathematical theorem." For this reaſon, he has confined conception to that faculty, whoſe province it is to enable us to form a notion of our paſt ſenſations, or of the objects of ſenſe which we have formerly perceived. The buſineſs of conception, thus defined, is to preſent us with an exact tranſcript of what we have felt or perceived. The firſt remarkable fact which ſtrikes us with regard to conception is, that we can conceive the objects of our ſenſes much more eaſily than thoſe of others. Thus, we can conceive an abſent viſible object much more eaſily than a particular ſound, a particular taſte, or a particular pain, which we have formerly felt. This peculiarity ſeems to ariſe from this circumſtance, that when we think of a ſound, or of a taſte, the object of our conception is one ſingle detached ſenſation; whereas every viſible object is complex, and the conception which we form of it as a whole, is aided by the aſſociation of ideas, which connects the different parts together, and preſents them to the mind in their proper arrangement; whilſt the various relations which theſe parts bear to one another in point of ſituation equally contribute to ſtrengthen the aſſociations. This power of conceiving viſible objects may be much improved by habit. Theſe obſervations, together with others adduced by our author, are applicable to conception as diſtinguiſhed from imagination, though the two powers are very nearly allied, and often ſo blended, that it is difficult to ſay to which of the two ſome particular operations of the mind are to be referred. Among logicians, it is a common, and almoſt an univerſal doctrine, that conception (or imagination, often uſed as ſynonymous with it) is attended with no belief of the exiſtence of its object. To this purpoſe, Dr. Reid ſays, "perception is attended with a belief of the preſent exiſtence of its object; memory with a belief of its paſt exiſtence; but imagination is attended with no belief at all; and was therefore called by the ſchoolmen *apprehenſio ſimplex.*" Profeſſor Stewart controverts the truth of this principle, and alleges ſeveral circumſtances in juſtification of his doubts concerning it. "If it were a ſpecifical diſtinction between perception and imagination, that the former is always attended with belief, and the latter with none; then the more lively our imagination were of any object, and the more completely that object occupied the attention, the leſs ſhould we be apt to believe its exiſtence; for it is reaſonable to think, that when any of our powers is employed ſeparately from the reſt, and there is nothing to withdraw the attention from it, the laws which regulate its operation will be moſt obvious to our obſervation, and will be moſt completely diſcriminated from thoſe which are characteriſtical of the other powers of the mind. So very different however is the fact, that it is matter of common remark, that when the imagination is very lively, we are apt to aſcribe to its objects a real exiſtence, as in the caſe of dreaming or madneſs; and we may add, in the caſe of thoſe who, in ſpite of their own general belief of the abſurdity of the vulgar ſtories of apparitions, dare not truſt themſelves alone with their own imaginations in the dark. That imagination is in theſe inſtances attended with belief, we have all the evidence that the nature of the thing admits of; for we feel and act in the ſame manner as we ſhould do, if we believed that the objects of our attention were real; which is the only proof that Metaphyſicians produce, or can produce, of the belief which accompanies perception." The author acknowledges, however, that in moſt caſes it is true that imagination is attended with no belief, if by belief we mean a permanent conviction which influences our conduct. But if the word be uſed in the ſtrict logical ſenſe, he inclines to think, that the exerciſe both of conception and imagination is always accompanied with a belief that their objects exiſt. From a variety of obſervations, which we cannot ſtate within the limits of this article, the ingenious profeſſor infers, that when the conceptions of the mind are rendered ſteady and permanent, by being ſtrongly aſſociated with any ſenſible impreſſion, they command our belief no leſs than our actual perceptions; and, therefore, if it were poſſible for us with our eyes ſhut to keep up for a length of time the conception of any ſenſible object, we ſhould, as long as this effort continued, believe that the object was preſent to our ſenſes. See NOMINALS, REALISTS, and UNIVERSALS.

CONCEPTION, in *Phyſiology*, denotes the changes which take place in the internal organs of generation of the female ſex, connected with the developement and growth of the embryo. See GENERATION.

CONCEPTION, *in Animals*, is ſaid to be occaſioned by ſomething emitted by the male, in the act of coition, impregnating and vivifying the rudiments of an animalcule contained in the female. To explain in what manner this is effected, and to ſhew

> "How the dim ſpeck of entity began
> T' expand its recent form and ſtretch to man,"
> Garth.

has been the object of anxious inquiry from the earlieſt ages. But though much learning has been expended on the ſubject, and ſeveral ingenious theories contrived, to explain the myſtery (ſee GENERATION), yet very little of real knowledge has been obtained.

In this place, without deciding whether the male ſperm contains the animalcule, or only a ſubtle aura, giving life to ſomething engendered in the female, it will be ſufficient to obſerve, that the firſt effect of impregnation, or conception, will be found in one of the ovaries, or female teſticles, as they are called (ſee OVARY), and not in the uterus, as was generally believed.

That the ovaries are neceſſary to conception, has been long known, as is evident by the practice of ſpaying (that is, taking out the ovaries of) ſows and other animals, to prevent their breeding. The late Mr. John Hunter took one of the ovaries out of a ſow (Obſ. on the Animal Œcon. 4to.), and found ſhe left off breeding two years ſooner, and produced fewer pigs at each litter, than another ſow, kept with her, that was perfect. The perfect ſow continued breeding ſix years, and produced 162 pigs; the half-ſpayed ſow continued to be fruitful only four years, and brought only 76 pigs: whence he concluded, that there is a certain limited number of eggs in each of the female ovaries, and when they are exhauſted, the animal is no longer fit for conception.

Anatomiſts, in the courſe of their examination of the bodies of females, have found hair, teeth, and other organiſed parts in the ovaries; and ova, containing fœtuſes, have been found in the Fallopian tubes. (See FALLOPIAN *tubes*, alſo FOETUS *extra uterine.*)

On carefully examining into the contexture of the ovaria, they are found to conſiſt of cluſters of veſicles, like bunches of grapes, which are ſuppoſed to be ova or eggs.

When one of the veſicles, or eggs, as they are called, become ripe, it enlarges, and puts on a yellowiſh hue, and if at this time it ſhould be impregnated by the male ſperm, it burſts the thin membrane that confines it to the ovarium, enters the fimbriated end of the Fallopian tube, and thence deſcends into the uterus.

The rent in the ovarium, through which the ovum had paſſed, forms a cicatrice, which is called, from its colour, *corpus luteum.* (See CORPUS *luteum.*) On diſſecting the ovaria, there are always found as many of theſe corpora lutea, as the woman, the ſubject of the diſſection, had borne children.

While impregnation, or conception, is taking place in the ovarium, and the fertilized ovum is deſcending through the Fallopian tube, a proceſs is going on in the uterus, to prepare it for its reception. The veſſels of the uterus, which were before ſo extremely minute, as not to be viſible, begin to be conſpicuous; the whole organ is enlarged, and a ſecretion of a mucus takes place, and lines its internal ſurface. This mucus ſoon puts on the appearance of a rough and ſhaggy membrane, deſtined to become the medium of connection between the ovum and the uterus. The late Dr.

William Hunter called this membrane the decidua, becauſe it is caſt off at the birth of the fœtus. He was ſuppoſed to have firſt diſcovered it; but Needham, who publiſhed his "Obſervations de formato Fœtu," in 1667, gives a clear deſcription of it and of its office, but acknowledges that his account is taken from brutes; he never having had an opportunity of opening the body of a woman who had died undelivered. There are three membranes, he ſays, lining the uterus of viviparous animals when pregnant; "extima prorſus fibroſa eſt, nulla vena, aut arteria viſibili donata," p. 176: it ſerves as a ſheath, he ſays, to the other membranes. Though he gives no name to this membrane, yet, as he places it between the chorion and the uterus, it can be no other than the decidua. Harvey deſcribes it alſo ſtill more diſtinctly. Before any veſtige of the conception can be ſeen, he ſays, "mucoſa quædam filimenta tanquam aranearum telæ, ab ultimo ſive ſuperiore cornuum angulo ducuntur; quæ ſimul juncta membranoſam ac mucilaginoſam tunicam, ſive manticam vacuam referunt." Exercit. ſexageſima nova.

The ovum being received into the uterus, in a little time, puſhes out ſmall fibres, or veſſels, principally, perhaps, from that part by which it had been connected to its calyx in the ovarium, in a manner not diſſimilar to that by which an acorn is joined to its cup, or a hazel nut to its outer green ſhell. Theſe veſſels, piercing the decidua, which affords a ſupport to them, inſinuate themſelves into the pores of the uterus, and abſorb the moiſture from it, for the ſupport and increaſe of the ovum, as the young fibrils, or ſlender radicles of plants and trees, abſorb their nouriſhment from the earth. Although the uterus is intended by nature, and is thus prepared for the reception of the ovum, yet if it happens to be detained in the Fallopian tube, or to fall into the cavity of the abdomen, it there puts forth its radicles, and attaches itſelf to the part it happens to fall upon, or be in contact with, and the incloſed fœtus is nouriſhed and comes to maturity nearly in the ſame manner, as if it had been received in its proper matrix. (See FOETUS *extra uterine*, alſo FOETUS, *Nouriſhment of, in Utero*.)

On examining the ovum, ſoon after its deſcent into the uterus, it appears to contain a clear glutinous fluid, like the white of an egg; in a little time a concretion, like a ſmall maggot, is ſeen in the centre of the fluid, which is the primordium of the embryo. Very minute blood-veſſels are now viſible, branching upon a part of the chorion, hereafter to become placenta; the little galba, or maggot, being attached to it by ſlender threads, ſcarce a line in length, the future funis umbilicalis. At one extremity of the concrete three veſicles are ſeen, the rudiments of the eyes and brain; and beyond them, a crimſon moving point, the punctum ſaliens, or heart. Soon after, fine white filaments are perceived, variouſly circumvoluted, the inteſtines. The reſt of the viſcera are now faintly delineated; then the integuments covering and confining the viſcera; then the extremities, or limbs, begin to ſprout, at firſt ſhort ſtumps, without hands or feet, which at length emerging, complete the transformation. The whole fœtus is ſaid to be completely formed, by the end of the fourth week from the time of conception. See Harvey, De Generat. Anim.: and his predeceſſor, under whom he ſtudied at Padua, Fabricius ab Aquapendente. For the further developement and growth of the fœtus, ſee EMBRYO, and alſo FOETUS.

CONCEPTION, *Symptoms of, in Women.* As ſoon as a woman hath conceived, a train of ſymptoms commence, which announce ſome conſiderable alteration has taken place. "Mulier ubi concipit," Hippocrates ſays, "ſtatim inhorreſcit, et incaleſcit, ac dentibus ſtridet, et articulos reliquumque corpus, convulſio prehendit, et uterum torpor." A woman, as ſoon as ſhe has conceived, ſhivers, and then becomes hot, her teeth chatter, and ſhe ſuffers a ſlight convulſive motion of her whole body. And in another place, "Pregnantem mulierem, ſi aliter non cognoſcas, oculi tracti, et caviores fiunt, et candidum oculorum albedinis naturam non habet, ſed lividius exiſtit." Op. Om. cura Vand. Linden. t. ii. p. 285. In pregnancy the eyes become hollow, the whites of them loſe their clearneſs, and become thick and muddy. If towards the end of the term of uterine geſtation, he adds, the eyes become hollow, and the face and the whole body are affected with œdema, if the tips of the ears and of the noſe are white, and the lips livid, the child will be found to be diſeaſed or dead. Andreas Laurentius, who was phyſician to Henry IV. of France, recites the following circumſtances, as indicative of a woman having conceived. "Nos mulierem concepiſſe exiſtimamus," he ſays, "ſi in ſeminum concurſu totum corpus leviter cohorruerit, aut titulatu quodam uterum contrahi perceperit; ſi exceptum cum voluptate ſemen non exciderit; ſi uteri os internum exquiſitè conniveat; ſi menſtrua ſubſiſtat purgatio; ſi lenis doloris ſenſus circa umbilicum et hypogaſtrium oberret; ſi mammæ obdureſcant, extuberant, perdoleant; ſi veneris appetentia langueſcat; ſi ocyſſimè lætatur, et ſubinde mœrore afficiatur; denique ſi in eduliis faſtidium." We know a woman to have conceived, if immediately after copulation ſhe is affected with ſhivering; if the ſemen, received with pleaſure, is not ſuffered to eſcape; if the mouth of the womb is found to be completely cloſed; if a ſlight ſenſe of pain is perceived about the navel; if ſhe ceaſes to menſtruate, and the breaſts become large, hard, and painful; if the appetite for venery abates; if ſhe has frequent and ſudden changes from mirth to ſadneſs; and, laſtly, if ſhe has a loathing to her uſual food, and a deſire for things before indifferent, or to which ſhe had an averſion. Theſe obſervations are in general juſt, and may ſerve to ſhew the accuracy with which the ancients noticed the minuteſt circumſtances; but they are for the greater part ſuch as we can make little uſe of in practice; as we ſhould neither be permitted to inquire whether a ſuperior degree of pleaſure was felt at the moment of coition, or whether the ſemen was retained, or to examine whether the os uteri was completely cloſed. Waving, therefore, theſe minutiæ, it will be ſufficient to deſcribe the moſt uſual ſymptoms attendant on conception and pregnancy, in the order they occur, and to make ſome obſervations on each of them, with the view of ſhewing the cauſes from which they are derived, and the means by which they may be mitigated, or appeaſed, when they are ſo violent as to endanger abortion, or are likely to occaſion any permanent evil to the conſtitution.

The firſt ſymptom by which women judge themſelves to have conceived, is an intermiſſion of the regular diſcharge of the menſes. This is ſo general, that women who have been accuſtomed to be regular, always date their conception from the time they firſt miſs their courſes, as they are popularly called; and in this judgment, they are almoſt conſtantly right, unleſs fever, or ſome other cauſe has intervened, to which the interruption of them may be attributed.

Nauſea and vomiting are alſo pretty conſtant attendants on pregnancy. Theſe are moſt troubleſome in the morning, and often commence before the period for meſtruation arrives. They have been ſuppoſed to be occaſioned by the ſubſidence of the uterus into the pelvis, dragging part of the bowels with it. But as they come on before the uterus has obtained ſufficient bulk to diſturb the bowels by its weight, they are with more propriety aſcribed to ſympathy, between the ſtomach and the uterus. Nauſea and vomiting, unleſs uncommonly violent, are rather to be eſteemed ſalutary than dangerous, and it has been obſerved, that women, attacked with theſe ſymptoms, are leſs liable to miſcarry, than thoſe who are free from them. Blood has even been known to be thrown up from the ſtomach, from the violence of the ſtraining, without any ſubſequent ill conſequence. When, however, the vomiting is extremely violent, and obſtinate, if there are alſo ſigns of plethora, or general fulneſs of the veſſels, two or three ſmall bleedings have often proved ſalutary. In the mean while the body ſhould be kept open, by adminiſtering gentle eccoprotics, which the coſtive ſtate of the bowels, incident alſo to pregnancy, makes particularly neceſſary. Infuſion of ſenna, with ſoluble tartar, or the bitter purging ſalt; lenitive electuary, rhubarb, magneſia, or caſtor oil, may be conveniently uſed, or emollient and opening glyſters, adminiſtered advantageouſly for this purpoſe. In the relaxed ſtate of the bowels, to which ſome delicate women are inclined, the confectio alkermes, or aromatica, given in weak cinnamon water, with three or four drops of the tincture of opium, twice or thrice a day, or from a quarter of a grain to a grain of opium may be given advantageouſly every night at bed time; where theſe have failed, the diarrhœa has been removed, by giving occaſionally, in addition to the above, ſmall doſes of ipecacuanha; or, laſtly, by change of air, all other methods having proved unſucceſsful.

The diſpoſition to vomiting uſually ceaſes between the fourth and fifth month, or ſoon after the woman has quickened, (ſee QUICKENING). The uterus now riſing above the brim of the pelvis, and entering into the cavity of the abdomen, is leſs preſſed upon by the neighbouring parts, and has more room for diſtenſion; perhaps alſo having been long uſed to the irritation, occaſioned by the increaſe of the ovum, it is leſs ſenſibly affected by it. In ſome conſtitutions, however, the ſickneſs and vomiting continue to haraſs the women through the whole courſe of pregnancy: yet even in theſe caſes, although the vomiting is ſo inceſſant, that the whole of what is taken into the ſtomach ſeems to be ejected that way, yet ſuch women have ordinarily as favourable labours, produce as healthy children, and recover from child-birth as ſpeedily and completely as thoſe who paſs through their pregnancy with only the uſual ſickneſs.

Subſidence, or falling in of the abdomen, ſo as to be leſs prominent than uſual, is conſidered as another of the early ſymptoms of pregnancy.

Dans une ventre plat
Un enfans il y a,

as the old French proverb has it. This has been ſaid to be occaſioned by the deſcent of the uterus into the pelvis, drawing with it a portion of the bowels, but with little propriety. The real cauſe ſeems to be emptineſs of the bowels: Women not only vomiting up the greater part of the food they take in, during the firſt five or ſix weeks of their pregnancy, but being uſually during that time ſo troubled with nauſea, as to have little inclination to take ſuſtenance.

The aureola, or circle round the nipple, which in virgins is of a beautiful pink colour, becomes darker, it is ſaid, after conception. It is certain, the aureola is darker in women who have had children, than in thoſe who were never pregnant, and in ſome women who have borne many children, it becomes of a dark chocolate colour, but as that colour continues after child-birth, no indication can be taken thence, whether the woman is actually pregnant, unleſs perhaps with the firſt child.

Enlargement, hardneſs, and tenderneſs of the breaſts, with pains darting through them, and a diſcharge of a thin paliſh milk, or whey, are commonly attendant on a pregnant ſtate. This alteration in the ſtate of the breaſts uſually takes place in the third or fourth month after conception, ſometimes earlier, and is indicative of the preparation making in them for the ſecretion of milk, the future nouriſhment for the child. If from this plump and firm ſtate, the breaſts ſubſide, and become looſe and flaccid, unleſs a violent diarrhœa may have ſupervened to occaſion it, the fœtus may be expected to be weak, ſickly, or dead.

Cardialgia, or heart-burn, is a frequent and troubleſome attendant on pregnancy. (See CARDIALGIA). This has obtained its name cardialgia, from its being ſuppoſed to be an affection of the cardia, or upper orifice of the ſtomach. A ſenſe of burning, or of intenſe heat, moleſts the patient, which demands almoſt inceſſant drinking to appeaſe it. As the uterus enlarges, it thruſts the inteſtines higher into the abdomen, hence the liver, and other viſcera, are diſturbed and ſtraightened, and thence probably a more plentiful ſecretion of bile, which flowing into the ſtomach, is thought to occaſion this uneaſy ſenſation, which is obſerved to be more troubleſome in a recumbent, than in an upright poſture. Pills with ſoap and rhubarb, Columbo root, magneſia, and other teſtaceous powders, are found to be the moſt uſeful medicines in this complaint. Milk and water, pyrmont and other chalybeate waters, bark and tonics are alſo ſerviceable; but it ſometimes reſiſts every medicine, and only ſubſides after the food is digeſted, and the ſtomach is nearly emptied. This points to the only preventive, abſtinence. Women ſubject to this complaint ſhould content themſelves with the lighteſt diet, and that taken in ſmall quantities. In the mean while, the rhubarb, ſoap, and Columbo, ſhould be perſiſted in to help digeſtion, and to cleanſe and empty the bowels.

Cramp, attacking the legs, thighs, or belly, is alſo a frequent attendant on the pregnant ſtate. This is probably occaſioned by the preſſure of the head, or other part of the fœtus on the iliac or neighbouring nerves, and conſequently becomes more troubleſome the farther the woman advances in her pregnancy. An unnaturally irritable ſtate of the nervous ſyſtem ſeems to be the pre-diſpoſing cauſe of this complaint. Hence, perſons in the higher ranks of life, whoſe conſtitutions are debilitated by ſitting up late at nights, by large companies, luxurious diet, &c. are moſt frequently tormented by it. A more ſimple diet, early hours, exerciſe in the open air, keeping the bowels empty, bark, and other bitter and tonic medicines, promiſe moſt, both in preventing and curing this troubleſome complaint.

Of the ſymptoms here enumerated, many are equivocal, as happening indifferently in the pregnant, or in the unimpregnated ſtate; and none of them are ſingly of ſufficient validity, to enable us to form a deciſive opinion from them; but from the conjunction of ſeveral of them, a pretty certain conjecture may be formed. If a woman accuſtomed to be regular, ſoon after marriage ceaſes to be ſo, and about the ſame time is affected with nauſea and vomiting, there would be little hazard in pronouncing ſuch a perſon to be pregnant. But where the ſymptoms are equivocal, it is always beſt to defer giving a deciſive opinion, until the commencement of the ſixth month, when from the motion of the fœtus, and the increaſed bulk of the abdomen, we may be enabled to determine with certainty.

About this time, a new train of ſymptoms ſucceeds, principally dependent on mechanical cauſes. The volume of the uterus, daily enlarging, preſſes on, and flattens the urinary bladder, and diminiſhes its capacity. Hence a more frequent neceſſity for making water. The uterus, at the ſame time, preſſing on the rectum, occaſions the alvine fæces to be diſcharged with difficulty; hence coſtiveneſs, and the return of the blood by the iliac and hæmorrhoidal veins being prevented, by the ſame cauſe, the piles; hence, alſo, œdematous ſwellings of the legs, thighs, and labia pudendi.

The labia pudendi, conſiſting almoſt entirely of cellular membranes, are ſometimes ſo enormouſly diſtended as to prevent the perſon from walking, and to occaſion conſiderable pain. Scarifying the labia, or making two or three punctures with a lancet, the parts being afterwards fomented with warm water, ſometimes ſucceeds in reducing theſe ſwellings. Bleeding and moderate purges are alſo neceſſary. However formidable the appearance of the labia, when thus enlarged, may be, they offer no impediment to the labour, which is frequently, in theſe caſes, uncommonly expeditious. In theſe leuco-phlegmatic habits, the fibres ſeem to have loſt their tone or power of reſiſting, and to give way to the ſlighteſt impulſe, ſo that the child is frequently expelled by the moſt trifling effort. The hæmorrhoids, or piles, are not ſo tractable, but frequently elude every attempt to cure them, until after delivery, when they uſually ſoon ſubſide.

Varices, or enlargement of the veins of the legs and thighs, being dependent on the ſame cauſes, the preſſure of the uterus, preventing the return of the blood from the lower extremities, can only be palliated, until after the birth of the child, when they gradually vaniſh. It will be right, while waiting for this event, to moderate the diſtenſion of the veins, and prevent their burſting, by keeping in a recumbent poſture, and by wearing bandages around the parts. The piles may be relieved by taking a deſert ſpoonful of cream of tartar every day, and by anointing them with a preparation, conſiſting of galls of Aleppo reduced to an impalpable powder, and mixed to the conſiſtence of an ointment with cold drawn linſeed oil, or green tea, macerated in boiling water, may be applied as a poultice.

An idea prevails among women, that it is neceſſary they ſhould take a greater quantity of nouriſhment during the pregnant ſtate, than at other times, as they are then to furniſh ſuſtenance to an additional being; and they frequently, at the exhortation of their friends, take in a greater quantity of food than they have any inclination for, leſt they ſhould deprive the child of its neceſſary nouriſhment. But as no more of the food they ſwallow can be of uſe for that purpoſe, than what is properly digeſted, and as all the ſymptoms ſhew the depreſſed ſtate of the ſtomach, it is evident that by loading that organ unneceſſarily, all the complaints incident to the pregnant ſtate will be aggravated and increaſed. The greater part of the bile being diſcharged by vomiting, during pregnancy, a ſufficiency does not remain to complete the digeſtion of the food, to which it greatly contributes. Hence the chyle, admitted in too crude a ſtate into the veſſels, by its ſtimulus, excites after every meal a kind of hectic, by which the body is emaciated, the face is contracted, or ſhrunk, and the eyes, as Hippocrates obſerved, become ſunk or hollow. In this ſtate, therefore, an increaſed quantity of food, by increaſing the labour of digeſtion, adds to the miſchief. A moderate diet, with a due quantity of vegetables, and of ripe fruit, with country air, when it can be obtained, are the beſt remedies, and are to be recommended in every caſe during pregnancy.

It has been obſerved, that the ceſſation of the menſes is one of the earlier ſigns of pregnancy; but ſome women continue to have a diſcharge of blood from the pudenda, recurring at longer or ſhorter intervals, for the firſt four, five, or ſix months of their pregnancy; but the return of theſe diſcharges is rarely regular, recurring at the end of the ſecond, third, or fourth week, and ſometimes at the end of longer intervals. The quantity alſo varies, being ſometimes more ſparing, at others more profuſe than the menſes uſually are. Theſe diſcharges happen whenever any portion of the placenta, or membranes, is detached from the uterus, and generally terminate in abortion, or the premature birth of the fœtus; or, if the woman carries her burthen to the end of the ninth month, the child is uſually weak, ſickly, or dead born. "Si pregnanti," Hippocrates ſays, in the place laſt quoted, "purgationes menſtruæ curſum ſuum teneant, bene valere fœtum eſt impoſſibile." A ſlender diet, with occaſional ſmall bleedings, and mild purges are the beſt preventives, in theſe caſes.

Pica, or an irregular or depraved appetite, exciting women to long for, or intenſely deſire, ſome particular kind of food, is ſometimes an attendant on pregnancy. (See Pica.) This formerly, from an improper indulgence of the appetites and fancies of pregnant women, was a very troubleſome, and ſometimes a formidable affection; as not only the health and life of the mother, but the perfection of the fœtus, were ſuppoſed to depend on gratifying theſe longings. If a child happened to be born with ſome mark or blemiſh on its body, the memory of the female relatives or friends was racked, to recollect ſome deſire of the woman that had been diſappointed, to which the accident was attributed. Sometimes, however, theſe marks were ſuppoſed to have been occaſioned by the ſudden ſight of ſome object, which it was thought to reſemble.

This idea of the power of the imagination of the mother, in marking or diſfiguring the fœtus, is ſo ancient that we can ſcarce trace its origin. We read in Geneſis, that Jacob placed peeled rods before the ewes when in company with the rams, "and it came to paſs, that when the ewes looked at the rods, that the lambs they yeaned, were party-coloured, and ſtreaked." And Heſiod, the moſt ancient of the Greek poets, ſays, "Ne quis rediens e funere, liberis operam det, ne imaginatio rei triſtis, in proles tranſeat, eaſque permutet." Let no one returning from a funeral, embrace his wife, leſt the melancholy he had contracted, ſhould make an impreſſion on the fœtus. Dr. Daniel Turner, who was an intire convert to the opinion, has made a large collection of ſtories of monſtrous births, all occaſioned, he ſays, by the diſappointed longings of their mothers, or by their being frighted by the ſight of ſome hideous or miſhapen objects. See his Treatiſe, De Morbis cutaneis. lib. xii. Turner's book was anſwered by Dr. Blondee, in a maſterly and ſatisfactory manner. The opinion is now wearing away very faſt, and bids fair in a little time to be totally obliterated. See Imagination.

When the appetite, during pregnancy, is inordinate or depraved, requiring improper food, it may be remedied by taking ſmall doſes of ipecacuanha, of rhubarb and magneſia, of Columbo, and other bitter and tonic medicines.

Conception, *immaculate*, of the Holy Virgin, is a feaſt eſtabliſhed in honour of the Holy Virgin; particularly with regard to her having been conceived and born immaculate: *i. e.* without original ſin; held in the Romiſh church on the 8th of December.

The Latin church, ſays Gibbon, (Hiſt. of the Decline and Fall of the Roman Empire, vol. ix. p. 265.) has not diſdained to borrow from the Koran the immaculate conception of the virgin-mother. It is darkly hinted in the Koran (c. 3. p. 39.) and more clearly explained by the tradition of the Sonnites. (Sale's Note, and Maracci, tom. ii. p. 112.) In the 12th century, the immaculate conception

tion was condemned by St. Bernard as a preſumptuous novelty. However Allatius, in his Prolegomena on Damaſcenus, endeavours to prove this feaſt to have been celebrated by ſeveral churches in the Eaſt, as early as the eighth century. It was firſt eſtabliſhed about the year 1138, though it is not known, with any degree of certainty, by whoſe authority it was introduced, nor in what place it was firſt celebrated; about 1140 certain churches in France began to obſerve it; but it had been obſerved in England, in conſequence of the zeal of archbiſhop Anſelm, before this period.

The church of Lyons in France was one of the firſt that adopted this new feſtival, but the canons of Lyons were ſeverely cenſured by St. Bernard for the innovation, and he vigorouſly oppoſed the immaculate conception of the Virgin, becauſe it ſuppoſed her being honoured with a privilege which belonged to Chriſt alone. Thus commenced a controverſy, which occaſioned two parties in the Chriſtian church that contended with each other for ſeveral centuries.

This has been a great ſubject of controverſy between the Scotiſts and Thomiſts; the former maintaining, and the latter impugning it.

The Dominicans eſpouſed the party of St. Thomas, and held out a long time in defence of the Virgin's being conceived in original ſin. When this controverſy was renewed at Paris in 1384, by John de Monteſono, a native of Arragon, a Dominican friar and profeſſor of divinity, who publicly aſſerted that all who believed the immaculate conception were enemies of the true faith, the college of divines, and the whole univerſity of Paris, condemned this and ſome other tenets of Monteſonus. Upon this the Dominicans, together with their champion Monteſonus, appealed from the ſentence of the univerſity to pope Clement VII. at Avignon, (the name aſſumed by cardinal Robert of Geneva, on his election during the pontificate of Urban VI.) and raiſed an outcry, that St. Thomas himſelf was condemned by the judgment paſſed upon their brother. But, before the pope could decide the affair, the accuſed friar fled from the court of Avignon, went over to the party of Urban VI., who reſided at Rome, and thus, during his abſence, was excommunicated. Whether or not the pope approved the ſentence of the univerſity of Paris is not aſcertained. The Dominicans, however, deny that he did, and affirm, that Monteſonus was condemned merely on account of his ſlight; though there are many others who aſſert, that his opinion was alſo condemned. And as the Dominicans would not acknowledge the ſentence of the univerſity to be valid, they were expelled in the year 1389, and were not reſtored to their ancient honours in that learned body till the year 1404. The council of Trent, ſeſſ. v. in the decree of *original ſin*, declares it not to be the intention of the council to include the Virgin under it; her conception it calls immaculate; and appoints the conſtitutions of Sixtus IV. to be obſerved with regard to it.

This controverſy between the Dominicans and Franciſcans was revived in the ſeventeenth century; and a feſtival was appointed by Clement XI. in 1708, to be celebrated throughout the Romiſh church: however, the Dominicans perſiſt in denying the obligation of this law, and in maintaining their ancient doctrines.

In the three Spaniſh military orders of St. James of the Sword, Calatrava, and Alcantara, the knights take a vow, at their admiſſion, to defend the immaculate conception. This reſolution was firſt taken in 1652.

Peter d'Alva and Aſtorga have publiſhed forty-eight huge volumes in folio, on the myſteries of the conception.

Conception, *Order of*, in Germany, was inſtituted in 1618, by Charles de Gonzaguez of Cleves, duke of Nivernois and Rheteblois, and was confirmed by pope Urban VIII. in 1624. The badge of this order was a golden croſs of eight points enamelled blue; in the centre a medallion rayonnated gold, thereon the image of the Virgin ſtanding on a creſcent, holding in her arms our Saviour, and round her head 12 ſtars all enamelled proper; the reverſe was enamelled as the front, and on the medallion St. Michael; the whole of the ſtar environed with the cordon of St. Francis, tied at the bottom: this badge was worn round the neck pendent to a ſky blue ribbon.

Conception, *religious of the order of*. See Theatines.

CONCEPTUALISTS, in *Logic* and *Metaphyſics*, a denomination given to a party of nominaliſts, who took a middle road between the two ſects of nominaliſts and realiſts, into which the ſcholaſtic philoſophers were divided from the beginning of the twelfth century. That univerſality, which the realiſts hold to be in things themſelves, and the nominaliſts in name only, the conceptualiſts hold to be neither in things nor in names only, but in our conceptions, whence they derived their appellation; but being expoſed to the batteries of both the oppoſite parties, they made no great figure. It is not an eaſy matter, ſays profeſſor Dugald Stewart (Elem. of the Philoſophy of the Human Mind, p. 192), to aſcertain preciſely the meaning of the conceptualiſts on the point in queſtion, their language on the ſubject being indiſtinct and inaccurate; but the profeſſor thinks that, upon the whole, it amounted to the two following propoſitions: firſt, that we have no reaſon to believe the exiſtence of any eſſences, or univerſal ideas, correſponding to general terms; and, ſecondly, that the mind has the power of reaſoning concerning genera, or claſſes of individuals, without the mediation of language. In denying the exiſtence of univerſals, the conceptualiſts agreed with the nominaliſts. To what then, can we ſuppoſe, ſays the profeſſor, that they differed from them, but about the neceſſity of language, as an inſtrument of thought, in carrying on our general ſpeculations? Mr. Locke is referred by Dr. Reid (Eſſays on the Intellectual Powers of Man, p. 478) to the claſs of conceptualiſts. He does not maintain, that there are things which are univerſal; but that we have general or univerſal ideas which we form by abſtraction; and this power of forming abſtract and general ideas, he conceives, to be that which makes the chief diſtinction in point of underſtanding between men and brutes.

If Mr. Locke, ſays profeſſor Stewart (ubi ſupra), had any decided opinion on the point in diſpute, it did not differ materially from what is ſtated in the general propoſitions, which we have already cited. The apparent inconſiſtencies which occur in that part of his Eſſay in which the queſtion is diſcuſſed, have led ſubſequent authors to repreſent his ſentiments in different lights; but as theſe inconſiſtencies plainly ſhew, that he was ſatisfied neither with the ſyſtem of the realiſts, nor with that of the nominaliſts, they ſeem to demonſtrate that he leaned to the intermediate hypotheſis already mentioned, notwithſtanding the inaccurate and paradoxical manner in which he has expreſſed it. Dr. Reid's opinion ſeems to the profeſſor to coincide nearly with that of the conceptualiſts; or, at leaſt, to coincide with the two propoſitions, which are ſuppoſed to contain a ſummary of their doctrine. The abſurdity of the ancient opinion concerning univerſals, as maintained both by Plato and Ariſtotle, he has expoſed by the cleareſt and moſt deciſive arguments; and by his own very original and important ſpeculations concerning the ideal theory, he has, in the ingenious profeſſor's opinion, completely deſtroyed that natural prejudice from which the whole ſyſtem of univerſal ideas gradually took riſe. If, even in the caſe of individuals, we have no reaſon to believe the exiſtence of any object of thought in the mind, diſtinct from the mind itſelf, we are at once relieved from all the difficulties in which philoſophers have involved themſelves, by attempting to explain, in conſiſtency with that ancient hypotheſis, the proceſs of the mind in its general ſpeculations. On the other hand, it is no leſs clear from Dr. Reid's criticiſms on Berkeley and Hume, that his opinion does not coincide with that of the nominaliſts; and that the power which the mind poſſeſſes of reaſoning, concerning claſſes of objects, appears to him to imply ſome faculty, of which no notice is taken in the ſyſtems of theſe philoſophers. However, he has no where poſitively aſſerted, that language is not an eſſential inſtrument of thought in our general reaſonings. At the ſame time, as he has not affirmed the contrary, and as he has declared himſelf diſſatisfied with the doctrines of Berkeley and Hume, his readers are naturally led to conclude, that this is his real opinion on the ſubject. His ſilence on this point is the more to be regretted, as it is the only point about which there can be any reaſonable controverſy among thoſe who allow his refutation of the ideal hypotheſis to be ſatisfactory. In conſequence of that refutation, the whole diſpute between the realiſts and the conceptualiſts falls at once to the ground; but the diſpute between the conceptualiſts and the nominaliſts (which involve the great queſtion concerning the uſe of ſigns in general ſpeculation) remains on the ſame footing as before. See Conception.

CONCERT, an aſſembly of muſicians, or a band of muſical performers aſſembled for the entertainment of muſical hearers.

Concert *Spirituel*, Fr. A concert of ſacred muſic, originally eſtabliſhed at Paris in 1725, by permiſſion of the manager of the opera; which permiſſion was purchaſed by the brother of the celebrated Philidor, to perform concerts in Lent, on the days the theatres were cloſed, at the price of 1000 livres a year, for three years, on condition that no French muſic or ſelections from the opera ſhould be performed at theſe concerts. This firſt gave birth to the uſe of foreign muſic and foreign muſicians in France. The licence was renewed from time to time, but always at an advanced price, till it amounted, in 1749, to 9000 livres a-year. In 1734, the two celebrated Bezzozi's, from Turin, performed at the concert ſpirituel, one on the hautbois and the other on the baſſoon, with more applauſe than any foreign muſicians had ever before received in France. The celebrated Mondonville had the direction of this concert for ſeveral years, and compoſed expreſsly for its uſe motets for a ſingle voice, accompanied by a rapid and difficult harpſichord leſſon. It was at the concert ſpirituel, which, like our oratorios, takes place when no dramatic performances are allowed, that Giornovichi, La Motte, Viotti, the Agujari, Madame Mara, the Todi, Savoi, and David, were firſt heard in France; and afforded the inhabitants of Paris an opportunity of comparing the muſic and performance of foreign muſicians with their own.

In 1749, during Lent, Geminiani had a concert of ſacred muſic at Drury-lane theatre, the vocal pieces were all Italian to Latin words. Geminiani himſelf led the band on this occaſion, and played one of his own ſolos. This performance, in imitation of the French, was called Concerto Spirituale.

In Italy and Spain, *academia*, Ital. implies a concert. In France, Academie Royale de Muſique, was the title given at Paris to the eſtabliſhment of the opera under Lulli by Louis XIV. in 1672, which it retained till the revolution. Rouſſeau, the ſcourge of French muſic and French muſicians, traduced both ſo much in his famous letter on French muſic, that he was burnt in effigy at the Opera-houſe door. And in the article Academie *Royale de Muſique*, in the Encyclopedie, and Dict. de Muſique, he has given great offence by a pun; when after barely mentioning this academy, he only adds—"I ſhall ſay nothing further concerning this celebrated eſtabliſhment, except that of all the academies in the world, this is that which has made the *moſt noiſe*," *(le plus de bruit)*.

Concert-*Pitch*. This term, among muſicians, implies that particular elevation of tone, as to gravity or acuteneſs, which ought to obtain between different muſical inſtruments intended to be uſed in concert, which, when thus adjuſted, are ſaid to be tuned, or in tune. In concerts entirely vocal, or thoſe wherein adjuſtable or perfect inſtruments only are uſed, as violins, violincellos, &c., any preciſe pitch being fixed for the notes is immaterial, ſo that all the inſtruments derive their notes from ſome *one* ſound, within moderate limits of the pitch in general uſe, and for which the inſtruments were by their dimenſions calculated; ſingers therefore uſually derive their pitch from a ſimple wind inſtrument called a Pitch-pipe (ſee that article), becauſe the ſame admits of taking their key-note a little higher or a little lower than the note marked on the ſtopper of the pipe, according to circumſtances, and the nature of the piece of muſic to be performed. Violin performers, when no keyed-inſtruments are preſent, uſually derive their pitch from a ſimple ſteel fork, tuned to the note A, called a Tuning-fork (ſee that article.)

Inſtruments, which either from their large and complicated conſtruction, as organs, piano-fortes, &c., or the fixed nature of their notes, as baſſoons, oboes, flutes, &c., cannot admit of the occaſional variation in the pitch of all their notes which we have mentioned above, are regulated by the makers and tuners of them, to what is called by ſome the *concert-pitch*, and by others the *opera-pitch*; though others maintain that the latter, or that uſed by the Italian opera band, is higher than the uſual concert-pitch of the country. It were much to be wiſhed, that one invariable pitch were adopted and uſed, but this cannot be hoped for, until the ſame is accurately expreſſed by the number of pulſes or vibrations excited in the air in a given time by the given note; and the number of theſe vibrations is eſſential to be known, before the theory of *beats*, as laid down by Dr. Robert Smith in his "Harmonics," the only general and accurate method of tuning inſtruments to a required temperament, can be applied. We ſhall therefore firſt explain the different methods which have been invented for aſcertaining the exact number of vibrations made by any given muſical ſound, and conſequently of fixing its *pitch*, and then relate ſuch experiments as have fallen within our knowledge for determining what is the preſent concert-pitch in this country.

The problem being of conſiderable importance, we ſhall enumerate eight different methods of ſolving it; in order that experiments may be varied in different ways, both for obtaining greater accuracy, and that the coincidence of their reſults may inſpire confidence in the minds of ſuch as have not ſufficient mathematical knowledge or patience to go through the inveſtigations, on which the theory of the vibrations of a muſical ſtring, and the *beats* of an imperfect conſonance are founded: and ſince the note C-*ſol-fa-ut*, or that on which the tenor-cliff is placed, being alſo the ledger line above the baſe ſtaff , or the ſame below the treble ſtaff of muſic , is now generally made the key-note, in ſtating the notes of the octave, whether diatonic or tempered, we ſhall adopt each of the formulas, to the finding of the pulſes made by this note in ten ſeconds of time, to be determined by a ſtop-watch, a ſecond pendulum clock, or a ſimple pendulum, uſed for the expreſs purpoſe of determining periods of 10″ each. (See PENDULUM.)

The *firſt* method was ſuggeſted by Pere Merſenne. It conſiſts in a wire or catgut ſtring, of about 15 to 17 feet in length, over two fixed bridges at its extremities; and after this, dividing the diſtance between the bridges accurately into eight equal parts; then fixing another bridge at one of thoſe diviſions from the end; taking care that the new bridge, which ſhould have a tolerably ſharp edge or top, does not ſtrain the ſtring, or force it out of its ſtraight line. The tuning-fork, pipe, or ſtring C, upon the inſtrument whoſe pitch is to be determined, is now to be compared with the ſound of the $\frac{1}{8}$th part of the ſtring; and if its double octave below nearly agrees therewith, the tenſion of the whole ſtring is to be altered, as in tuning a ſtringed inſtrument, either tightening or ſlackening it, until the $\frac{1}{8}$th part is in exact uniſon with the double octave below the note C, without any beats or undulations: if the ſound of the $\frac{1}{8}$th of the ſtring ſhould be found on trial to give a clear muſical note, and yet differ very materially from the double octave below C, it may be neceſſary to aſſume a greater or leſſer length between the extreme bridges, and to determine anew the place of the bridge for the $\frac{1}{8}$th part thereof: and after the $\frac{1}{8}$th part has been nicely adjuſted to the double octave below the note C, as above, it will be proper again to compare the meaſure of the $\frac{1}{8}$th part of the ſtring with its whole length, to ſee that the points of bearing on the bridges are accurately adjuſted to theſe proportions. Now remove carefully the middle bridge, and cauſe the whole ſtring to vibrate, which it will be found to do ſo ſlowly, as not to cauſe an audible ſound, [if any ſound is heard, it will be one of the HARMONICS of that note, ſee that article, and TRUMPET], but ſo that its number of vibrations in 10″ can be ſeen and counted, eſpecially if a quill be held ſo near to the middle part of the ſtring, that it may touch it at each extremity of its vibration; 32 times the number of theſe vibrations will give the number of pulſes or complete vibrations made by C in 10″, and may be called its pitch.

The *ſecond* method is that which Dr. Robiſon uſed, wherein a machine, conſiſting of a combination of wheel-work, could be ſo regulated by the motion of a fly, that any given number of the teeth of a wheel ſhould paſs and ſtrike a quill projecting againſt them, during the ſpace of 10″. In uſing ſuch a machine as this, the velocity of the laſt wheel ſhould be ſo regulated, that the ſound produced by the ſnaps of the quill againſt the teeth, ſhould be in exact uniſon with the note C; when the known number of teeth which ſtrike the quill in the given time, will determine the pitch.

The *third* method is by the ſame learned and ingenious gentleman, who contrived an apparatus, regulated in the manner laſt deſcribed, which opened and ſhut the paſſage to an even current of air, produced by a pair of bellows, ſuch as are uſed in organs, any required number of times in 10″; this ſingular apparatus was found to give a clear muſical ſound, which regulated to an uniſon with C, gave the exact pitch thereof, by the number of alternate openings and ſhuttings of the cock in 10″.

The *fourth* method is founded on the following propoſition, by the author laſt mentioned, *viz.* "An open organ pipe, when ſounding its fundamental note, undulates with one node in its middle, and its undulations are analogous, in reſpect of their mechaniſm, with the vibrations of a wire of the ſame length, and the ſame weight, with the column of air in the pipe, and ſtretched by a weight equal to that of a column of the ſame air, reaching to the top of a homogeneous atmoſphere, or equal to the weight of a column of mercury, as high as that in the barometer." (See PIPES, *Theory of the Sound of*, TRUMPET, &c.) Whence this ſimple practical rule, when the barometer ſtands at about 30 inches, and the thermometer at about 55°, *viz.* divide the number 226620 by the length in inches and tenths, of an open cylindrical pipe which ſounds C, and the quotient will be the number of pulſes or complete vibrations made thereby in 10″.

The *fifth* method conſiſts in ſuſpending a known weight (equal to W grains) at one end of a wire, ſuch as is uſed for the loweſt notes of a piano-forte, the other end of which is lapped round a thumb-peg, ſuch as is uſed for tuning a violin, ſcrewed tightly into the wainſcot, near to an inſtrument whoſe pitch is to be determined; then by turning the peg, lengthen or ſhorten the vibrating part of the wire, until when ſtruck it ſounds exactly a double octave below C; meaſure exactly the length of the vibrating part of the ſtring, between its contact with the peg and the loop which ſuſtains the weight; call this L inches. After this, cut off exactly L inches of this ſame wire and weigh it, call its weight W grains; then will the number of complete vibrations or pulſes made by C in 10″ be found by the following theorem; *viz.* $\sqrt{\frac{154463 \times W}{L \times W}}$. See our article CHORDS.

The *ſixth* method is by Dr. Robiſon, and is as follows. Let a violin-guitar, or any ſuch inſtrument, be fixed up againſt a wall with the finger-board downwards, and in ſuch a manner that a violin-ſtring, ſtrained by a weight, may preſs on the bridge, but hang free of the lower end of the finger-board. Let another ſtring be ſtrained by one of the tuning-pins, till it be in exact uniſon with C, then hang weights on the other ſtring, till upon drawing the bow acroſs both ſtrings at a ſmall diſtance below the bridge, they are found to be perfect uniſons, taking care that the preſſure of the bow on the ſtrings is ſo moderate, as not to affect the tenſion of the ſtring firſt tuned. Then, having noted carefully the weight appended to the firſt ſtring, add one-fortieth part thereof to the ſame. Now draw the bow carefully again acroſs the ſtrings as before, and an audible *beating* will be heard between the ſounds of the two ſtrings; count the number of theſe beats during 10″, and 80 times this will be the number of complete vibrations, or pulſes, made by C in 10″.

The *ſeventh* method, as well as the beſt, depends on tuning a major comma; for which ſeveral rules are given under the article COMMA. From the octave below C tune upwards three ſucceſſive perfect *fifths* upon a ſingle ſtop of an organ, C G, G D, and D A; and thence tune downwards the perfect major *ſixth*, A C; which laſt C will be a major comma above the firſt C, and will beat conſiderably when ſounded therewith; count theſe beats during 10″, and 81 times this will be the number of complete vibrations, or pulſes of C in 10″. See Dr. Smith's Harmonics, p. 195.

The *eighth* method (Harmonics, p. 197.) conſiſts in tuning a major a major *ſixth*, C A, above C, not perfect, but ſuch that it may beat ſharp B times in 10″; from thence tune downwards three ſucceſſive perfect *fifths*, A D, D G, and G C; which laſt note will be an imperfect octave below C, the beats of which octave are to be counted during 10″, carefully diſtinguiſhing whether it beats ſharp or flat, and calling the number, if ſharp, S, and if flat, F; then will $81S + 16B$, or $16B - 81F$, according as the caſe may be, expreſs the number of complete vibrations, or pulſes of C in 10″.

It is not in our power to give ſo ſatisfactory an account of what is the preſent concert or opera-pitch in this country, as we could have wiſhed; but we hope that experiments will hereafter be multiplied, for fixing it very exactly (at a mean ſtate of the barometer and thermometer), and after ſuch determination, that the exact number of pulſes or complete vibrations from one extreme of the vibrations of a ſtring until its return to the ſame point, will be reſorted to by inſtrument-makers and tuners, for regulating the pitch of their forks, pipes, and inſtruments.

The vibrations, mentioned in M. Euler's experiment, (after our fifth method, under our article CHORDS) were ſemi-vibrations, or thoſe made, while a point in a muſical ſtring, went from and returned to the axis, or line of reſt, between the two points of ſuſpenſion, and not complete vibrations, or thoſe made while the ſtring went from and returned to the place of its greateſt deviation from the axis: therefore $\frac{392}{2}$, or 196, was the number of complete vibrations per 1″, made by the A, a minor third below our C; whence this made $\frac{6}{5} \times 196 \times 10 = 2351$ complete vibrations in 10″.
